HNO_3 . It is also decompd. by H_2O , Et_2O and alc.; *acetophenone nitrate*, properties similar to the BzH deriv.; BzPh.HNO_3 ; $(\text{C}_6\text{H}_5)_2\text{CO.HNO}_3$; $(\text{C}_6\text{H}_5\text{CO})_2\text{HNO}_3$; *benzil nitrate*, yellow prisms, unstable in the air; PhCH:CHCHO.HNO_3 ; *camphor nitrate*; *benzaldehyde picrate*, long, yellow prisms, m. $70-2^\circ$, unstable; $\text{BzMe.HO(NO}_2)_2\text{C}_6\text{H}_5$; *cinnamylaldehyde picrate*, yellow prisms, m. $66-7^\circ$. On standing for 3 months in a desiccator it lost 5% PhCH:CHCHO ; *dibenzalacetone picrate*, orange, rhombic crystals, m. $113-4^\circ$, quite stable; *asobenzene nitrate*, red crystals, extremely unstable; *asobenzene picrate*, red crystals; *stilbene picrate*, brown needles, m. $94-5^\circ$. No addition products of HNO_3 with unsatd. hydrocarbons could be isolated, the resulting products being NO_2 derivs. or resins.

D. BREESE JONES.

Bromination of aniline. H. FRANZEN AND A. HENGLEIN. Karlsruhe. *J. prakt. Chem.* 91, 245-57(1915).—A new and convenient method of prep. $p\text{-BrC}_6\text{H}_4\text{NH}_2$, and $2,4\text{-Br}_2\text{C}_6\text{H}_3\text{NH}_2$. PhNBrCHBrPh was obtained in 83% yield as a yellow powder by slowly adding 80 g. Br in 80 cc. CHCl_3 to 90 g. PhN:CHPh in 150 cc. CHCl_3 , and allowing to stand 1 hr. at 0° . On boiling with abs. alc. for 1 hr. it is converted into *benzylidene-p-bromoaniline hydrobromide*, bright, yellow cryst. powder, m. 215° (decompn.), which on warming in abs. alc. with $\text{C}_6\text{H}_5\text{N}$ loses HBr and is converted into *benzylidene-p-bromoaniline* (a), leaves, m. 67° . Yield, 90%. The 2 above reactions are thus represented: $\text{PhNBrCHBrPh} \longrightarrow p\text{-BrC}_6\text{H}_4\text{NHCHBrPh} \longrightarrow p\text{-BrC}_6\text{H}_4\text{N:CHPh}$. On warming 170 g. of (a) in 200 cc. abs. alc. + 500 cc. dil. HCl , and removing the BzH by distn. with steam, $p\text{-BrC}_6\text{H}_4\text{NH}_2$ was obtained in 61% yield. In an analogous way, starting out with $p\text{-BrC}_6\text{H}_4\text{N:CHPh}$, $2,4\text{-Br}_2\text{C}_6\text{H}_3\text{NH}_2$ and $2,4,6\text{-Br}_3\text{C}_6\text{H}_2\text{NH}_2$ were prepd., the 2 compds. being readily sepd. by heating the mixt. with dil. H_2SO_4 , whereby the $2,4,6$ -deriv. forms an insol. salt. *Benzylidene-p-bromoaniline dibromide*, dark yellow, amorphous powder, m. 182° . Yield, 84%. *Benzylidene-2,4-dibromoaniline hydrobromide*, yellow, cryst. powder, which with $\text{C}_6\text{H}_5\text{N}$ is converted into $2,4\text{-Br}_2\text{C}_6\text{H}_3\text{NH}_2$ in 48% yield; *2,4-dibromoaniline derivative*, yellow needles, m. 67° ; *dibromide derivative*, orange needles, m. $115-20^\circ$ (decompn.); yield, 68%. On boiling with alc. it gave $2,4,6\text{-Br}_3\text{C}_6\text{H}_2\text{NH}_2$. $\text{Br}_2\text{C}_6\text{H}_4\text{HNH}_2$ could not be made by this method.

D. BREESE JONES.

Ethyl orthoformate as an alkylating agent. F. VON WALTHER. Dresden. *J. prakt. Chem.* 91, 258-60(1915).—The prepn. of some nitrophenetoles by action of HC(OEt)_3 on the corresponding nitrophenols. As is the case with other strong acids, picric acid in H_2O readily hydrolyzes HC(OEt)_3 , but when heated alone in an oil bath up to 170° for 0.5 hr., the 2 components yield $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OEt}$, white needles from ligroin, m. 78.5° . Under the same conditions the reaction of $2,4\text{-C}_6\text{H}_3(\text{NO}_2)_2\text{OH}$, which is a weaker acid, with HC(OEt)_3 is incomplete, but a 50% yield of $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{OEt}$ was obtained by distg. the components over a free flame, and occasional addition of HC(OEt)_3 to compensate for the amt. which distils over unchanged, white needles, m. 86° .

D. BREESE JONES.

Cycloglycylglycines. Direct synthesis by the action of glycerol upon amino acids. L. C. MAILLARD. *Ann. chim.* 3, 48-120(1915); cf. *C. A.* 6, 495, 621; 8, 3423. —M. presents arguments in favor of his nomenclature for the cyclic dipeptides and describes in detail a number of homologs in the cycloglycylglycine series that have been mentioned but not characterized in his previous articles. A comprehensive, critical review of the work of other investigators in this field shows that all of the compds. described by M. have been previously synthesized. *Cyclosarcosylsarcosine*, prepd. by the usual methods, bitter needles, m. $149-50^\circ$, was found to be identical with the anhydride obtained by Traube (*Ber.* 15, 2110) and by Mylius (*Ber.* 17, 286). *Cycloalanylaniline* (A), needles, m. $282-2.5^\circ$, was shown to be the *dl*-mixt., identical with Fischer's *dl*-alanine anhydride (3,6-dimethyl-2,5-diketopiperazine; cf. *Ber.* 34, 433).

An unidentified by-product in the formation of (A) was probably an alkaloid of the pyrazine series. *dl*-Leucine was the parent substance of *dl*-cycloleucylleucine (B), needles, m. 271°, identical with *dl*-leucinimide, m. 271°, prepd. by Fischer (*Ber.* 34, 433; 35, 1075; 37, 2486) and by other investigators. An unidentified by-product in the formation of (B) from leucine responded to the usual alkaloidal reactions and was probably a pyrazine deriv.

LOUIS E. WISE.

Plurality of starches. CHARLES TANRET. *Bull. soc. chim.* 17, 83-97(1915).—A large part of this work has been previously outlined (cf. *C. A.* 8, 2964-5). Starch is apparently an intimate mixt. of amylose and amylopectin. Pure (?) amylose is rapidly dissolved when starch is treated with boiling H₂O for a few min., whereas the amylopectins are ordinarily insol. under these conditions. Pure amylopectin solns. may be obtained by heating starch with H₂O at 130° in sealed tubes and quant. removing the amyloses by fixation upon washed cotton or cellulose material. Amylopectin solns. give purplish red colorations with I, while amylose solns. give the typical starch-I blue coloration. A series of expts. was made in which fixed wts. of an anhydrous starch (from a known source) were treated with fixed wts. of H₂O at temps. ranging from 45-100°. The solns. were allowed to cool and the dissolved amylose colorimetrically detd. by comparison with the standard blue coloration with I, produced by a definite amt. of pure amylose. T. finds that the amt. of amylose remaining in soln. depends on the temp. at which the expt. was carried out. Starches from different sources furnish varying % of "amylose" (at a definite temp.). T. concludes that "amylose" is probably a mixt. of different homologous "amyloses," and that the "plurality" of starches has been definitely proven. Pure amylopectin preps. swell in cold H₂O. The "gelatinization" of starch caused by hot H₂O probably results from the simultaneous soln. of amylose and the swelling of amylopectins. "Skins" formed in concg. starch solns. are due to sepn. of amyloses.

LOUIS E. WISE.

Iodohydrins of phenylcyclohexene and phenylmethylcyclohexene. M. L& BRAZIDEC. *Bull. soc. chim.* 17, 97-109(1915); cf. *C. A.* 9, 614.

L. E. W.

Action of acetic anhydride upon alkaloids of the morphine series. II. Morphine bases in which acetic anhydride causes no rupture of the nitrogen linkage. M. TIF-FENEAU. *Bull. soc. chim.* 17, 109-14(1915); cf. *C. A.* 9, 1747.—T. shows that diacetyl-morphine, acetylcodeine, acetylmorphine and acetylthebaine are not acted upon by Ac₂O. **III. The apomorphine series. Diacetyl and triacetyl apomorphine.** With PORCHER. *Ibid* 114-9; cf. *C. A.* 8, 3191.—Upon heating 3 g. apomorphine-HCl with 10 cc. Ac₂O for 20 hrs., T. and B. obtained a mixt. of 2.4 g. *diacetyl apomorphine* (A), needles from AcOEt-petr. ether, m. 129°, [α]_D -47.2° (in Ac₂O), and 1.45 g. *triacetyl apomorphine* (B), m. 137°, purified by crystn. from Et₂O-AcOEt. *Hydrochloride* of (A), forms stable aq. solns., [α]_D -67.26° (H₂O). *Methiodide* of (A), m. 233°. (A) is an emetic, but (B) possesses no emetic properties.

LOUIS E. WISE.

Catalytic hydrogenation of liquids under the influence of common metals at moderate temperatures and pressures. A. BROCHET. *Bull. soc. chim.* 17, 124-30 (1915); cf. *C. A.* 9, 1602, 1746.—A more detailed description of the reduction of indigo to indigo white by means of H in the presence of active Ni. The rate of H absorption by indigo solns. has been graphically represented in 3 expts. by taking the number of cc. of H absorbed per min. as ordinates and the time in min. as abscissas. Max. absorption is reached after 15-20 min.

LOUIS E. WISE.

Action of sodamide upon allyldialkylacetophenones. II. Preparation of 3,5-dimethyl-3-ethyl- and 3,3-diethyl-5-methylpyrrolidones. A. HALLER AND E. BAUER. *Compt. rend.* 160, 541-3(1915); cf. *C. A.* 8, 2673.—Allyldialkylacetophenones, BzCRR'-

$\text{CH}_3\text{CH}_2\text{CH}_2$, reacting with NH_2Na , yield 3,3-dialkyl-5-methyl-2-pyrrolidones, $\text{RR}'\text{C}(\text{CH}_3)\text{CHMe.NH.CO}$ and PhH . Thus $\text{BzCMeEtCH}_2\text{CH:CH}_2$ gives rise to

3,5-dimethyl-3-ethyl-2-pyrrolidone, m. 82° , b_{16} $134-6^\circ$, and $\text{BzCEt}_2\text{CH}_2\text{CH:CH}_2$ yields 3,3-diethyl-5-methyl-2-pyrrolidone, m. $49-50^\circ$, b_{16} $144-6^\circ$. LOUIS E. WISE.

Biochemical synthesis of the mono- α -D-galactoside of ethyleneglycol. E. BOURQUELOT, M. BRIDEL AND A. AUBRY. *Compt. rend.* 160, 571-3 (1915).—Ethyleneglycol mono- α -D-galactoside (A), $\text{C}_6\text{H}_{11}\text{O}_5 \cdot \text{O} \cdot \text{CH}_2\text{CH}_2\text{OH}$, microneedles, m. $133-4^\circ$, $\alpha = 0^\circ$, without action upon Fehling soln. and quant. hydrolyzed by either dil. H_2SO_4 or emulsin, was prepd. by the following method: 300 cc. of an aq. soln. ($[\alpha]_D$ $18^\circ 20'$) of 261 g. $(\text{CH}_2\text{OH})_2$, 35 g. galactose and 5 g. emulsin was kept at 33° for about 2 months, 3 g. of fresh emulsin added, the mixt. kept at lab. temp. until the const. $[\alpha]_D$ $13^\circ 32'$ had been reached, and then treated with 3 vols. of 95% EtOH, and filtered. After removal of EtOH, H_2O and $(\text{CH}_2\text{OH})_2$ by distg. under diminished pressure, the sirupy residue was treated with 400 cc. H_2O and 4 g. of fresh bottom yeast and 5 g. glucose to insure galactose fermentation. After standing 10 days, the fermented liquor was concd. to 100 cc., 300 cc. EtOH added, the soln. filtered, concd. further to a sirup, which after treatment with successive portions of dry AcOEt, to remove traces of $(\text{CH}_2\text{OH})_2$, was extd. with abs. EtOH. These exts., after evapn. to dryness, resoln. in abs. EtOH and addition of Et_2O , yielded (A). LOUIS E. WISE.

Action of acylamino acid chlorides on sodiomalonic ester. IV. E. IMMENDÖRFFER. Univ. Berlin. *Ber.* 48, 605-16 (1915); cf. Gabriel, C. A. 9, 313.—*N*-Methyl-*C*-diethylglycine nitrile, $\text{MeNHCET}_2\text{CN}$, in 34 g. yield from 25 g. KCN and 25 g. $\text{MeNH}_2 \cdot \text{HCl}$ in 100 cc. H_2O shaken 3 hrs. with 60 cc. Et_2CO , b_{745} $165-7^\circ$, smells of camphor, produces headache, sol. in H_2O with strong alk. reaction; *picrate*, lemon-yellow needles, decomps. 98° ; *chloroplatinate*; *chloroaurate*, rectangular, mostly quadratic tables; *hydrochloride*, m. $76-7.5^\circ$. From 13 g. of the cold nitrile treated slowly with 14 cc. BzCl and then shaken 3 hrs. with 40 g. KHCO_3 in 160 cc. H_2O is obtained 21 g. *N*-methyl-*C*-diethylhippuronitrile, 6-sided plates from alc., m. $112-2.5^\circ$; 10 g. introduced in the course of about 1 hr. into 20 cc. cold H_2SO_4 with const. stirring and poured upon ice gives 10 g. of the acid, needles or elongated 6-sided plates from C_6H_6 or AcOEt, m. 186° , converted by 10 parts of boiling 20% HCl into *N*-methyl-*C*-diethylglycine hydrochloride, rhombic tables and prisms from alc., m. $246-7^\circ$; free glycine, sublimes in voluminous flocks without melting, seps. from 50 parts alc. in striated prisms, forms no Cu salt. The hippuric acid, warmed 3 hrs. with SOCl_2 , gives the chloride which with boiling MeOH yields the methyl ester, needles from petr. ether, m. $89-91^\circ$. Dimethyl *N*-methyl-*C*-diethylhippurymalonate, from the above chloride (from 5 g. acid) in 2 vols. $\text{CH}_2(\text{CO}_2\text{Me})_2$ and 0.84 g. Na and 16 cc. $\text{CH}_2(\text{CO}_2\text{Me})_2$ in 100 cc. C_6H_6 shaken overnight at 38° (yield, 2.5 g.), granular crystals from ligroin, m. $106-8^\circ$, regenerates the hippuric acid on heating with H_2O or moist solvents, while 1 g. cautiously warmed in 3 cc. HI and finally boiled 10 min. gives BzOH , the above glycine and 1-methyl-2-diethyl-5-phenylpyrrolone, leaves from Et_2O , m. 138° ; *picrate*, m. about 152° ; *chloroaurate*; *chloroplatinate*. *N*-Methyl-*C*-methylethylglycine nitrile, in 7 g. yield from 6 g. KCN, 5 g. $\text{MeNH}_2 \cdot \text{HCl}$ and 12 cc. AcEt in 30 cc. H_2O at 40° , b_{718} $149-54^\circ$; *hydrochloride*, hygroscopic; *picrate*, m. $88-9^\circ$ (decompn.); *chloroplatinate*, 6-sided golden brown plates, blackens 235° ; *chloroaurate*, scales. The nitrile (11.2 g.) with 13 cc. BzCl and 12 g. calcined soda, shaken 3 hrs. with 30 cc. H_2O , gives 21 g. of the hippuronitrile, plates from 1.5-2.0 parts alc., m. $81-2^\circ$; free acid (yield, 90%), needles from 16 parts C_6H_6 , m. $164-5^\circ$; *chloride*, yellowish crystals; *methyl ester*, leaflets from ligroin, m. $85-7^\circ$. *N*-Methyl-*C*-methylethylglycine, rectangular plates from alc., sublimes without melting. Dimethyl *N*-methyl-*C*-methylethylhippurymalonate, in 1.2 g. yield from 5 g. of the above

chloride, 1.4 g. Na and 12 cc. $\text{CH}_3(\text{CO}_2\text{Me})_2$ in 75 cc. C_6H_6 , rhombic plates from ligroin, m. $116-8^\circ$ (112° if heated slowly); 0.7 g. with 2 cc. of HI (d. 1.7) gives 0.12 g. of 1-methyl-2-methylethyl-5-phenylpyrrolone, needles from ligroin, m. $91.5-3.0^\circ$; hydrochloride, hydroiodide (needles), picrate (needles), chloroaurate. *N*-Ethyl-*C*-dimethylglycine nitrile, in 28.5 g. yield from 23 g. $\text{EtNH}_2\cdot\text{HCl}$ and 25 g. KCN in 100 cc. H_2O shaken 3 hrs. with 40 cc. acetone, b₇₆₁ $143-4^\circ$; hydrochloride, hygroscopic prisms, m. $109-10.5^\circ$; picrate, needles, darkens 158° , m. $166-8^\circ$; chloroplatinate, 6-sided plates; chloroaurate, needles. From 11.2 g. of the base and 12 cc. BzCl is obtained 20 g. *N*-ethyl-*C*-dimethylhippuric nitrile, rhombic plates from alc., m. $76-8^\circ$, b. about 275° (slight decompn.), partially hydrolyzed on long standing with soda, also losing BzOH on boiling; acid, 4-sided prisms and rhombic plates from AcOEt , m. $161.5-2.0^\circ$. *N*-Ethyl-*C*-dimethylglycine, prisms from $\text{AcOH}\cdot\text{EtOH}$, sublimes without m.; hydrochloride, prisms from $\text{EtOH}\cdot\text{Et}_2\text{O}$, m. $249-51^\circ$ (decompn.). Chloride, m. above 145° . Methyl ester, needles, m. 68° . Dimethyl *N*-ethyl-*C*-dimethylhippurymalonate, m. $111-3^\circ$. 1-Ethyl-2-dimethyl-5-phenylpyrrolone, quadrangular prisms from ligroin, m. 50° ; hydroiodide, m. 170° , quickly turns yellow; picrate, needles, m. $145-6^\circ$. *p*-*N*-gem.-Tetramethylhippuric nitrile, in 10 g. yield from 9 g. *p*- $\text{MeC}_6\text{H}_4\text{COCl}$ and 6 g. MeNHCM_2CN , plates and prisms from alc., m. 133° . Acid, rhombic plates from alc., m. 205° . Dimethyl *p*-*N*-gem.-tetramethylhippurymalonate, in 0.6 g. yield from 2 g. of the chloride of the above acid, 0.9 g. Na and 8 cc. $\text{CH}_3(\text{CO}_2\text{Me})_2$ in 50 cc. C_6H_6 , yellowish 4-sided plates from ligroin, m. $98-103^\circ$. *p*-Tolyltrimethylpyrrolone, plates, m. 125° ; picrate, m. $134.5-6.0$; hydroiodide; hydrochloride; chloroaurate; chloroplatinate. *m*-*N*-gem.-Tetramethylhippuric nitrile, in 12 g. yield from 14 g. *m*- $\text{MeC}_6\text{H}_4\text{COCl}$ and 8.5 g. MeNHCM_2CN , plates from alc., m. 86° ; acid, m. 169° . Dimethyl *m*-*N*-gem.-tetramethylhippurymalonate, in 1.5 g. yield from 6.7 g. of the above acid (converted into the chloride), 1.4 g. Na and 12 cc. $\text{CH}_3(\text{CO}_2\text{Me})_2$ in 75 cc. C_6H_6 , needles from ligroin, m. $112-4^\circ$. *m*-Tolyltrimethylpyrrolone, thin plates from ligroin, m. 83° ; picrate, needles, m. 154° ; hydroiodide; hydrochloride; chloroaurate; chloroplatinate. In the hope of obtaining $\alpha\text{-NH}_2$ ketones of the type $\text{NH}_2\text{CM}_2\text{COCH}_2\text{X}$ ($\text{X} = \text{alkyl}$) (Gabriel, C. A. 7, 2570) from $\text{C}_6\text{H}_5(\text{CO})_2\text{NCMe}_2\text{COCHNa}(\text{CO}_2\text{R})_2$ with EtI instead of MeI it was found that the salt is slowly converted into Et benzoylenedimethylpyrrolonecarboxylate on heating with acetone or EtI , immediately on boiling with H_2O , while the EtI , probably owing to steric hindrance, does not react with it, or only very slowly. C. A. R.

1,4-Dibiphenylenebutadiene. WILHELM WISLICHENUS. Univ. Tübingen. *Ber.* 48, 617-24 (1915).—The yellow-red hydrocarbon originally obtained from alc. fluorene, NaOEt and HCO_2Et and thought to be a methenylbisfluorene (*Ber.* 35, 765 (1902)) but since obtained under various conditions (C. A. 5, 482) is also formed on long standing of fluorene and alc. ethylate but in good yield only when atm. O has an abundant chance to react; the compd. has now been shown to be 1,4-dibiphenylenebutadiene (a); it is probably identical with Pummerer and Dorfmueller's "dehydrothylidenebisfluorene" (C. A. 7, 3342), Mayer's red by-product "A" (C. A. 8, 94) and Stollé's "dehydrobenzylidenebisfluorene" (C. A. 8, 119). From 20 g. fluorene allowed to stand, protected from moisture and CO_2 , for 3-4 weeks in 200 g. Et_2O with 7 g. K in 50 g. alc. and treated twice a day for about 0.5 hr. each time with dry air or O free from CO_2 , is obtained about 10 g. of crude (a) as a red-yellow ppt. mixed with a small amt. of a red to dark red substance; the ppt. is washed with Et_2O and H_2O , dried, freed from unchanged fluorene with boiling Et_2O and extd. with C_6H_6 or xylene, the 1st exts. removing the more sol. red by-product. The solns. of (a) in org. solvents are pure yellow but deposit red-yellow prisms becoming deep scarlet above 200° , m. $372-4^\circ$ (partial sublimation), sol. in cold fuming H_2SO_4 with blue color quickly changing to green; warmed with AlCl_3 in PhNO_2 it gives a deep green color changing to a turbid red; with CrO_2 -

AcOH is formed fluorenone; slow distn. with Zn dust in H gives fluorene; with Cl or 10-2 mols. SO_2Cl_2 in CHCl_3 is obtained a *chloro derivative*, $\text{C}_{21}\text{H}_{18}\text{Cl}_4$, m. $215-9^\circ$ (gas evolution), forms a red substance with alc. KOH. *Picrate* of (a), $\text{C}_{22}\text{H}_{18}\cdot 2\text{C}_6\text{H}_3\text{O}_7\text{N}_3$, m. about 260° (decompn.), regenerates (a) with hot aq. NH_3 . Boiled with excess of Zn dust in 150 cc. of AcOH until the soln. is almost colorless, 1 g. of (a) gives *dibiphenylenebutene* (b), yellowish needles from C_6H_6 , m. $267-8^\circ$, behaves like (a) towards fuming H_2SO_4 and AlCl_3 in PhNO_2 , absorbs 6 atoms of Br, with evolution of HBr, in CCl_4 . (a) heated 3 hrs. at 220° with 6 mols. of 57% HI and a little P or (b) in alc. boiled with 2.5% Na-Hg give *dibiphenylenebutane*, m. 225° , sol. in fuming H_2SO_4 without color, behaves like (a) and (b) towards AlCl_3 in PhNO_2 , absorbs 4 atoms Br, with evolution of HBr.

CHAS. A. ROULLER.

Some derivatives of α -amino- α -methylbutyric acid and α -amino- α -ethylbutyric acid. PAUL FREYTAG. Univ. Berlin. *Ber.* 48, 648-57(1915); cf. Gabriel, *C. A.* 5, 1426.— α -*Phthalimido- α -methylbutyric acid* (a), $\text{C}_8\text{H}_4(\text{CO})_2\text{NCMeEtCO}_2\text{H}$, short needles from H_2O , m. $141.5-3.0^\circ$, is obtained by gradually introducing NH_3 - $\text{CMeEtCO}_2\text{H}$ into 1 mol. melted $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$, heating to quiet fusion to 160° , pouring into a warm dish, cooling, powdering, rubbing up with cold H_2O and soda, filtering and pptg. with HCl; 0.29 g. dissolves in 100 cc. H_2O at 22° , 0.9 g. at 100° . *Silver salt*. The part of the reaction product insol. in soda (about 0.1 of the NH_3 acid used) is *bi-gem.-methylethyldiketopiperazine*, $\text{CMeEt.NH.CO.CMeEt.NH.CO}$, tables or slender

needles, m. 340.5° ; solubility in 100 cc. alc., 0.60 and 1.80 g. at 27° and 78° , resp., in 100 cc. H_2O , 0.24 and 0.51 g. at 27° and 100° . α -*Phthalimido- α -ethylbutyric acid* (b), prepd. like its homolog except that the temp. is raised to 200° , m. $161-2^\circ$; *silver salt*, browns 218° ; m. 232° (decompn.). In the prepn. of the acid there is also formed as by-product *tetraethyldiketopiperazine*, m. $346-6.5^\circ$; solubility in alc., 0.75 and 1.80 g. in 100 cc. at 26° and 78° ; in 100 cc. H_2O , 0.11 and 0.22 g. at 26° and 100° . *Chloride* of (b), from (b) and PCl_5 , needles from ligroin, m. $73-5^\circ$; 4 g. in 40 cc. C_6H_6 , slowly treated with 4 g. AlCl_3 , allowed to stand overnight, decompd. with ice, dil. HCl and 2 drops of dil. HNO_3 and freed from C_6H_6 with steam gives a thick tar, a portion of which was converted by warm 33% KOH and a little MeOH into the phthalaminic acid which, when boiled with concd. HCl, almost completely dissolves; on cooling, phthalic acid seps. and concn. of the filtrate yields an easily deliquescent substance which is probably α -amino- α -ethylbutyrophenone hydrochloride, $\text{BzCET}_2\text{NH}_2\cdot\text{HCl}$; its aq. soln. yielded easily sol. rodlets with AuCl_3 and PtCl_4 in H_2O and alc.; Na picrate gave yellow rodlets which with KOH yielded oily drops volatile with steam and having the odor of aromatic amines. The tar, therefore, undoubtedly contained α -*phthalimido- α -ethylbutyrophenone*. When another portion of this tar was recrystd. twice from a little alc., it yielded about 20% of *phenyl- $[\alpha$ -hydroxyphthalimidyl]- α -ethylbutyric lactone* (I), flat needles, m. $133-4^\circ$; 2 g. boiled a few min. with 1.5 cc. of 33%

KOH and 5 cc. each of H_2O and alc. gives 0.8 g. of an *acid* (II) or (III), platelets and broad rodlets, sinters 199° , m. 201° , which, when boiled 2 hrs. with 20 parts of 5% HCl, yields $\text{BzC}_6\text{H}_4\text{CO}_2\text{H}$ and $\text{H}_2\text{NCEt}_2\text{CO}_2\text{H}$. These 2 acids are obtained directly when 2 g. of the lactone in 8 cc. AcOH is heated 3 hrs. at 138° with 6 cc. fuming HCl. *Diphenylphthalimidyl- α -ethylbutyric acid* (IV), obtained in 3 g. yield from the chloride from 10 g. (b) treated slowly in 60 cc. C_6H_6 with 20 g. AlCl_3 , heated 2 hrs. on the H_2O bath, cooled, decompd. with ice and dil. HCl, steam distd. and the resulting tar repeat-

edly extd. with hot aq. NH_3 and the exts. pptd. with HCl , 6-sided elongated crystals from AcOH or C_6H_6 , m. 254° , converted by 3 hrs. heating at 140° with AcOH -fuming HCl into phthalophenone and $\text{H}_2\text{NCEt}_2\text{CO}_2\text{H}$. Chloride of (a), oil; the product from 10 g. (a), treated in 50 cc. C_6H_6 with 15 g. AlCl_3 and boiled 1 hr., yields 2 products: (1) α -phthalimido- α -methylbutyrophenone, elongated 6-sided plates from alc., m. $78-80^\circ$, giving with fuming HCl - AcOH after 1.5 hrs. in a xylene bath α -amino- α -methylbutyrophenone hydrochloride; chloroaurate and -platinate, rodlets; picrate, yellow prismatic rodlets, m. 193° ; free base, oil; (2) diphenyl- α -phthalimidyl- α -methylbutyric acid, rhombic columns from alc., needles from C_6H_6 , m. 283° , sol. in concd. H_2SO_4 with green color, hydrolyzed to phthalophenone and $\text{H}_2\text{NCMeEtCO}_2\text{H}$. The yield of this acid is increased by increasing the amt. of AlCl_3 and the length of heating (3 hrs.), 4.2 g. being obtained from 10 g. (a). When 22 g. (b) is warmed with 18 g. PCl_5 until liquid, freed from POCl_3 in *vacuo* at 100° and then cautiously heated over a free flame, energetic decompn. with gas evolution sets in and a yellow greenish oil distils over, solidifying to a yellowish cryst. mass (17.5 g.) which seps. from much H_2O , 5 parts alc. or 50% AcOH in needles which on distn. form fatty, H_3BO_3 -like scales, m. 83° , are volatile and have a peculiar overpowering odor; they are γ -phthalimidopentene, $\text{C}_6\text{H}_4(\text{CO})_2\text{NCEt}:\text{CHMe}$, and with boiling HI give $\text{C}_6\text{H}_4(\text{CO})_2\text{NH}$ and Et_2CO . Similarly, from the chloride of (a) is obtained β -phthalimidobutene, $\text{C}_6\text{H}_4(\text{CO})_2\text{NCMe}:\text{CHMe}$ or $\text{C}_6\text{H}_4(\text{CO})_2\text{NCEt}:\text{CH}_2$, m. 90° , b_p 215° ; it absorbs 2 atoms Br in C_6H_6 , giving the dibromide, leaflets from ligroin, m. $77-8^\circ$, which loses HBr in *vacuo* at 100° ; on heating over a free flame, an oily mixt. distils over from which by fractional crystn. from petr. ether were isolated β -phthalimidobromobutene, rodlets, m. $92-3^\circ$, and another substance, m. 130° .

CHAS. A. ROUILLER.

Epifucose. EMIL VOTOCEK AND J. CERVENY. Prag. Ber. 48, 658-60(1915).—Fuconic lactone was transformed in the usual way (heating with aq. $\text{C}_6\text{H}_5\text{N}$, best 4 hrs. at $145-50^\circ$) into epifuconic acid which was sepd. from the unchanged fuconic acid by repeated crystn. of the Ba salts from H_2O or pptn. from H_2O by alc., the progress of the sepn. being followed under the microscope until the salt consisted solely of needles. From this salt were prepd. the free epifuconic acid and its lactone and the latter reduced with Na-Hg , giving epifucose as a viscous syrup becoming quite hard in *vacuo* over H_2SO_4 , $[\alpha]_D$ about -9° , and yielding a phenyl- and *p*-bromophenylosazone, m. 204° , identical with those obtained from fucose.

CHAS. A. ROUILLER.

Triarylmethyls. XIII. *m*-Quinoids. W. SCHLENK AND MAX BRAUNS. Univ. Jena. Ber. 48, 661-9(1915).—A careful repetition of the work of Stark (C. A. 8, 1118) gave results entirely different from his and showed that the hydrocarbon obtained by the action of metals on $m\text{-C}_6\text{H}_4(\text{CPh}_2\text{Cl})_2$ (a) is not a *m*-quinoid but a bis-triarylmethyl, thus affording further evidence that *m*-quinoids are not capable of existence. The results obtained by Stark were probably due to the presence of some *p*-compd. in his (a) and to the fact that he did not exclude atm. O with sufficient care. Schlenk and B. found that for the prepn. of (a) absolutely free from the *p*-compd. it is necessary to start from a $m\text{-C}_6\text{H}_4(\text{CO}_2\text{H})_2$ free from the slightest trace of the *p*-acid; such a product is best obtained from (*m*- MeC_6H_4); 150 g. $[3,4\text{-Me}(\text{H}_2\text{N})\text{C}_6\text{H}_3]_2$ in dil. HCl is pptd. as the HCl salt with much concd. HCl , drained off, rubbed to a thin paste with H_2O , diazotized at room temp. with N_2O_5 (from As_2O_5 and HNO_3), filtered into 4 l. alc., slowly treated with 300 g. Zn dust, decanted, boiled 1 hr. with 200 g. fresh Zn dust, cooled, filtered, distd. until an oily turbidity appears in the distg. flask, cooled, the oil sepd., the aq. alc. liquid dild. with much H_2O , extd. with Et_2O , the ext. combined with the oil, washed with H_2O , dried, distd., and the distillate freed from any remaining base with gaseous HCl . There is thus obtained 75 g. (MeC_6H_4); 20 g. is added to a hot mixt. of 500 cc. concd. H_2SO_4 in 700 cc. H_2O and 160 g. CrO_3 in 300

cc. H_2O , boiled overnight, cooled, dild. with H_2O and the crystd. $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$ purified by dissolving in H_2O and a little NH_3 , filtering and pptg. with HCl . Yield, 9–10 g. To prep. (a), 140 g. PhBr in 300 cc. Et_2O is converted into the Grignard reagent and the hot soln. treated dropwise with 30 g. $m\text{-C}_6\text{H}_4(\text{CO}_2\text{Me})_2$ in 200 cc. C_6H_6 , boiled 4 days, cooled, decompd. with ice and dil. H_2SO_4 , the Et_2O layer dried, freed of Et_2O and C_6H_6 on the H_2O bath, the residue taken up in hot benzene (b. $100\text{--}50^\circ$), cooled, and the amorphous deposit pptd. from 8 parts AcOH by satg. with gaseous HCl ; the cryst. (a) thus obtained is again pptd. from AcOH with HCl , boiled 1 hr. with 2.5 parts each of AcCl and C_6H_6 and distd. on the H_2O bath; on cooling (a) deposits in prisms, m. 140.5° , very sensitive to moisture. When shaken in C_6H_6 under CO_2 with mol. Ag , 1 Cl atom is removed, the soln. becoming intensely yellow, owing to the formation of the monovalent radical $\text{ClCPh}_2\text{C}_6\text{H}_4\text{CPh}_2\dots$; this soln. eagerly absorbs O and at once becomes colorless, but in a few moments the yellow color returns and can again be destroyed by shaking with air; after 4–5 repetitions of this process, the soln. becomes permanently colorless, indicating the existence of an equil.: 1 mol. colorless hexaarylethane $\rightleftharpoons$ 2 mols. colored triarylmethyl, which is destroyed by formation of a colorless superoxide by the triarylmethyl. The yellow soln. shows a characteristic band spectrum (narrow, sharply defined, very dark band at $\lambda 513\text{--}7$, with complete absorption in the visible spectrum from $\lambda 493$). The CPh_2Cl group still remaining can easily be detected by running a drop of the soln. upon melted PhOH , the latter becoming intensely red-brown. The removal of this 2nd Cl atom requires much more energetic treatment; shaking for days in C_6H_6 in sealed tubes under CO_2 with a large excess of mol. Ag will not affect its removal but on boiling with Cu bronze the yellow soln. after a time becomes violet, owing to the formation of the bivalent radical, $\text{C}_6\text{H}_4(\text{CPh}_2\dots)_2$. In thin layers this soln. is blue and shows an intense band at $\lambda 576\text{--}636$, sharply defined towards the red, less sharply towards the green; on shaking with air it instantly and permanently becomes colorless. On concn. it deposits a substance of the comp. $\text{C}_{20}\text{H}_{14}$, which, however, is no longer identical with the free bistriarylmethyl, for it is colorless and its solns. in boiling xylene or anisole are also colorless. It is apparently a complicated condensation product. XIV. Theory of the "quinocarbonium salts." W. SCHLENK AND R. OCHS. *Ibid* 676–80; cf. *C. A.* 8, 2728.—Tri- α -thienylmethyl perchlorate (a), which cannot have a quinoid structure, is in all respects analogous to Ph_3CClO_4 , indicating that the so-called "quinocarbonium" colored triarylcannabinol salts are really simply carbonium compds. α -Iodothiophene, light yellow oil, b.₁₀ 78° , is obtained in 40–4 g. yield from 37 g. $\text{C}_4\text{H}_5\text{S}$ and 112 g. HgO in 150 cc. C_6H_6 treated with 111 g. I in 15 g. portions in the course of 15 min., sepd. from the HgI_2 and excess of C_6H_6 , washed with C_6H_6 and fractionated; 30 g. in 120 cc. Et_2O are treated in the usual way with 10 g. Mg shavings, cooled, decanted from the excess of Mg, treated about 0.5 hr. with CO_2 and decompd. with ice and dil. H_2SO_4 , giving 15–9 g. of $\alpha\text{-C}_4\text{H}_5\text{SCO}_2\text{H}$, m. 124° ; 16 g. of the acid in 150 cc. alc. treated 2 hrs. with dry HCl yields 14 g. of the Et ester, b.₁₈ 96° ; 6 g. of this ester in 20 cc. Et_2O is slowly dropped into a boiling soln. prepd. by treating 16 g. $\text{C}_4\text{H}_5\text{SI}$ in 100 cc. Et_2O with 4 g. Mg shavings and pouring from the excess of Mg; after 2 hrs. boiling, the reaction mixt. is decompd. with ice and H_2SO_4 and extd. with Et_2O ; the dark red-brown soln. of triethienylcannabinol thus obtained is at once treated with 6 cc. of 70% HClO_4 , whereupon (a) seps. in crystals with blue luster, deflagrates on heating, forms a yellow-brown powder, gives in $(\text{CHCl}_3)_2$ an intensely yellow soln. showing a characteristic broad absorption band and conducting the elec. current. XV. Some bistriarylmethyls. W. SCHLENK AND MAX BRAUNS. *Ibid* 716–28; cf. *C. A.* 7, 2578.—When 30 g. $p\text{-Ph-C}_6\text{H}_4\text{I}$ in 100 cc. Et_2O is boiled 2.5 hrs. with 10 g. Mg powder activated by Baeyer's method, decanted from the excess of Mg, dild. with 100 cc. C_6H_6 , treated hot with 5 g. ($p\text{-MeO}_2\text{CC}_6\text{H}_4$), in small portions and boiled 4 hrs. there is obtained p,p' -biphenylene-

bis[dibiphenylcarbinol], $[\text{C}_6\text{H}_4\text{C}(\text{C}_6\text{H}_4\text{Ph})_2\text{OH}]_2$, needles from xylene, m. somewhat above 260° , colored intensely violet by concd. H_2SO_4 , the soln. showing an intense band at λ about 610–480, sharply defined towards the red, less sharply towards the blue; treated 0.5 hr. in boiling xylene containing a little AcCl with dry HCl , it gives *p,p'*-biphenylenebis[dibiphenylchloromethane], needles with 1 mol. xylene, m. about 271° , sol. in molten PhOH with intense dark violet color; 2 g. boiled 0.5 hr. in 75 cc. C_6H_6 under CO_2 with 10 g. Cu bronze gives *p,p'*-biphenylenebis[dibiphenylmethyl], identical with Schmidlin's " β -tribiphenylmethyl" (*C. A.* 7, 1017), blue needles with strong green metallic luster, whose blue soln. shows a band at λ about 660–570. Although its mol. wt. could not be detd. because when once dry it is no longer easily sol., it is doubtless monomol. for its blue solns. are instantly and permanently decolorized by shaking with air; the peroxide so formed could not be obtained pure; it seps. from C_6H_6 -gasoline as a white powder with 87.46% C and 5.8% H . [$p\text{-C}_6\text{H}_4\text{CPh}_2\text{OH}$] (Chichibabin, *Ber.* 40, 1812 (1907)), obtained in 10 g. yield from the Grignard reagent from 12 g. PhBr in 100 cc. Et_2O added to 9 g. ($p\text{-BzC}_6\text{H}_4$) suspended in 100 cc. C_6H_6 and boiled 3 hrs., seps. with 1 C_6H_6 ; its yellow-red soln. in $\text{AcOH-H}_2\text{SO}_4$ shows a strong band at λ about 550–480; 8 g. in 120 cc. Et_2O satd. with HCl at room temp. and treated with 20 cc. AcCl gives the bischloromethane which, shaken 1 day with Cu bronze in C_6H_6 , gives the bis[diphenylmethyl], crystals with green metallic luster, forming a dark powder whose intensely red-violet solns. show a band at λ about 600–540. The ($p\text{-BzC}_6\text{H}_4$)₂ is obtained as silvery needles from PhNO_2 , m. 216° , in 28 g. yield from 50 g. each BzCl and AlCl_3 on the H_2O bath treated with 20 g. Ph_3 in small portions. *m,m'*-Biphenylenebis[diphenylcarbinol], flat prisms and tablets from xylene, m. $183\text{--}4^\circ$, colors concd. H_2SO_4 orange-red, is obtained in 8 g. yield from the Grignard reagent from 18 g. PhBr in 100 cc. Et_2O boiled 48 hrs. with 5 g. (*m*- $\text{MeO}_2\text{CC}_6\text{H}_4$)₂ in 100 cc. C_6H_6 ; 5 g. boiled 0.5 hr. with 50 g. AcCl and 50 cc. C_6H_6 gives the bischloromethane in lancet-shaped crystals, m. $175\text{--}6^\circ$, colors PhOH intensely dark brown; 1.5 g. shaken 24 hrs. in 12 cc. C_6H_6 under CO_2 with 8 g. Hg gives the bis[diphenylmethyl] in colorless needles, forming orange-red solns. with 2 bands; an intense one at $\lambda_{512\text{--}20}$ and a faint one at $\lambda_{481\text{--}93}$; the soln. is at once decolorized by air but after a few sec. the color reappears; this phenomenon may be repeated 8–10 times before the decolorization is permanent, indicating that the substance is considerably associated in soln.; a 3% soln. in freezing C_6H_6 gave a mol. wt. of 880. Attempts to prep. the isomeric *o,o'*-compd. failed because the impure, badly crystg. *biscarbinol* when treated with HCl and AcCl gave, instead of the chloromethane, anhydro-*o,o'*-biphenylenebis[diphenylcarbinol], $(\text{C}_6\text{H}_4\text{-CPh}_2)_2\text{O}$, m. $291\text{--}3^\circ$, unchanged by heating with PCl_5 in PCl_5 . Tetraphenyl-*o*-xylene-glycol, obtained in 18 g. yield from the PhMgBr from 30 g. PhBr in 100 cc. Et_2O boiled 24 hrs. with 20 g. phthalophenone in 200 cc. C_6H_6 , prisms from C_6H_6 -benzine, m. 198° , sol. in H_2SO_4 with dark orange-yellow color. All attempts to convert it into the dichloride (with HCl , AcCl , SO_2Cl_2 , PCl_5) failed, the product, which is also obtained with the most varied dehydrating agents, being tetraphenylphthalane, $\text{C}_6\text{H}_4(\text{CPh}_2)_2\text{O}$, needles, m. $174\text{--}5^\circ$, sol. in H_2SO_4 with orange-yellow color.

Preparation of glucosaminic acid. HANS PRINGSHEIM AND GERHARD RUSCHMANN. Univ. Berlin. *Ber.* 48, 680–2 (1915).—The acid is obtained in 9.7 g. yield when 20 g. glucosamine-HCl in 400 cc. H_2O is treated with 110 g. yellow HgO , heated on the H_2O bath with frequent shaking until the Hg ppt. becomes gray, boiled 5 min. over a free flame, filtered, decompd. with H_2S on the H_2O bath, filtered, concd. *in vacuo* at $50\text{--}60^\circ$ to incipient crystn., allowed to stand 24 hrs. in the ice chest, filtered from the 1st crop of the acid, again concd. *in vacuo* to about 100 cc., and completely pptd. in the cold with 96% alc. The combined crops are dissolved in the necessary amt. of hot H_2O and again pptd. with alc. when cold.

A. P. LOTHROP.

Behavior of keratin sulfur and cystin sulfur, in the oxidation of these proteins by potassium permanganate. I. TH. LISSIZIN. Univ. Moscow. *Biochem. Bull.* 4, 18-23(1915).—Human hair was digested with 2% KMnO_4 . In the mass of dissolved oxidation products, 9% of the total S occurred as H_2SO_4 , 2.5% as oxyprotosulfonic acid and 88.5% as H_2O -sol. organic substance. A method is outlined for the isolation of this latter substance, which is pptd. by Pb acetate, is slightly sol. in dil. alc., insol. in 95% alc., acid in reaction, very hygroscopic, gives the biuret reaction, and is decompd. by mineral acids with the formation of H_2SO_4 . When cystin was oxidized in a similar manner, 47% of the S was split off as H_2SO_4 and among the oxidation products a small amt. of H_2S was always present; H_2S is never found in the distillates of the oxidation products of hair.
A. P. LOTHROP.

Organic phosphorus compounds of wheat-bran. CHARLES J. ROBINSON AND J. H. MUELLER. Univ. Louisville, Ky. *Biochem. Bull.* 4, 100-17(1915).—The organic P of wheat bran is present mainly in the form of phytin, similar to that from many other sources. It is most readily sepd. from a 0.2% HCl ext. of bran by pptn. with Cu acetate. A cryst. tri-Ba salt is readily prepared. There is also present another substance, similar in compn., which forms a Ba salt containing 34% Ba as compared

with 38% in Ba phytate. It does not dialyze, indicating that the mol. is larger than that of Ba phytate. A third compd. which differs widely from phytin, containing more C and less P, can be sepd. It yields a pentose on hydrolysis and forms a Ba salt containing only 31% Ba. It has not been obtained in cryst. form and its compn. is uncertain; the formulas, $C_6H_{18}O_{24}P_2Ba_2$, for the Ba salt and $C_4H_{14}O_{24}P_2$, for the acid accord most closely with the analytical results but the agreement is not entirely satisfactory. Influence of low temperatures upon enzymes. JOSEPH S. HEPBURN. *Biochem. Bull.* 4, 136-50(1915); *J. Frank. Inst.* 179, 581-5(1915).—A review. A. P. L.

Does butter-fat contain nitrogen and phosphorus? THOMAS B. OSBORNE AND ALFRED J. WAKEMAN. Conn. Agr. Expt. Sta. *J. Biol. Chem.* 21, 91-4(1915).—The growth-promoting substance in butter-fat is concd. in the butter-oil that remains after the removal of the solid fraction by crystn. from alc. at -20° . If this butter-oil does contain P and N, it is present in such minute amt. as to make its isolation impossible. The traces of N and P that have been detected in butter-fat were probably derived from butter-milk in the butter before centrifugalization; butter-milk is rich in both N and P. These expts. apparently exclude from the list of possible substances, that might be the cause of the growth-promoting power of butter-fat, all compds. containing either N or P. A. P. LOTHROP.

Studies of autolysis. I. The accelerating effect of manganous chloride on liver autolysis. H. C. BRADLEY AND MAX MORSE. Univ. Wis. *J. Biol. Chem.* 21, 209-21(1915).—In dil. solns., pig and dog livers autolyze until about 25% of the total N cannot be pptd. by tannic acid; about 75% is undigested, even in the presence of active enzyme. If $MnCl_2$ is added, from 75 to 90% of the N is sol. in tannic acid and the undigested residue consists chiefly of connective tissue. The equil. is changed proportionately by the addition of $MnCl_2$ until a conc. of 0.1 M is reached; increasing conc. beyond this gradually diminishes the speed and lowers the equil. point. The $MnCl_2$ appears to alter the normally resistant liver proteins in such a way as to render them digestible by liver protease, thus increasing the effective mass of substratum in the digest. "The pseudo-equilibria represent therefore true points of equil., detd. by the mass of proteins constituting the effective substratum present in each case. The other proteins present are unavailable and exercise no influence on the equil. of the reaction." A. P. LOTHROP.

Comparative rate of oxidation of enzymes and their corresponding pro-enzymes. W. E. BURGE. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 357(1915).—Pepsinogen is more resistant to oxidation than pepsin, trypsinogen than trypsin. J. F. LYMAN.

The diastases of the blood. HUGH MCGUIGAN AND C. L. V. HESS. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 359-60(1915).—Diastase is present in dog blood. A quant. method for diastase in blood is described. J. F. LYMAN.

Oxidation in the red corpuscles of the goose. J. F. MCCLENDON. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 364-5(1915).—Induction shocks failed to show any increase in intracellular oxidation. J. F. LYMAN.

Oxidizing power of oxyhemoglobin. J. F. MCCLENDON. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 366(1915).—Recrystd. oxyhemoglobin and methemoglobin oxidized 0.01 N α -naphthol and *p*-phenylenediamine as rapidly as solns. of red corpuscles of equiv. concn. J. F. LYMAN.

The production of enzymes and its causes. H. ZIKRS. *Monatsh. Landw.* 7, 24; *Biedermanns Zentr.* 44, 68-9(1915).—Z. cultivated in glucose soln. for 14 yrs. a strain of yeasts capable of fermenting saccharose. When these were again brought into a saccharose soln. after about 300 or 400 subcultures had been made $(NH_4)_2SO_4$

and asparagine as N source), a strong fermentation took place at once. The same result was obtained when freshly killed yeasts from the glucose soln. were used. Similar expts. carried out with maltose soln. also gave the same results. The conclusion is drawn that the yeast contains both invertase and maltase in the form of a zymogen.

C. F. MILLER.

Studies on amylases. VIII. The influence of certain acids and salts upon the activity of malt amylase. H. C. SHERMAN AND A. W. THOMAS. *J. Am. Chem. Soc.* 37, 623-43 (1915).—Weak acids (acetic, propionic, phosphoric), strong acids (HCl, HNO₃, H₂SO₄), and acid phosphates (Na and K) produced optimum activation of malt diastase in concentrations corresponding to the same actual acidity— $p_H^+ = 4.2$ to 4.6, detd. electrometrically. Special methods for the purification of the enzyme, starch, and reagents are given. It is stated that measurements of the amylolytic action of purified amylase cannot be used for comparison with measurements of the saccharogenic action of the same prepn. **IX.** Experiments upon the purification of malt amylase. H. C. SHERMAN AND M. D. SCHLESINGER. *Ibid* 37, 643-8 (1915).—A new method of purification, consisting of dialysis at low temp. and pptn. with (NH₄)₂SO₄ and alc., yielded maltase of max. activity—1570. The most active prepn. contained 15.2% N, less than that obtained by Osborne (*J. Am. Chem. Soc.* 18, 536-42). The higher diastatic power and lower N content are ascribed to the low temp. of dialysis, which minimizes the possible hydrolysis of the enzyme itself in the process of prepn.

W. A. PERLZWEIG.

Amylases. X. Comparison of certain properties of pancreatic and malt amylase preparations. H. C. SHERMAN AND M. D. SCHLESINGER. Columbia Univ. *J. Am. Chem. Soc.* 37, 1305-19 (1915); cf. preceding abstr.—Although the best amylase prepn. obtained in S.'s lab. from the pancreas and from malt are very similar in physical properties and chem. nature, they do not seem to be identical. Malt amylase is most active in an acid soln., while pancreatic amylase is most active in an alk. soln. In the presence of its proper activating electrolyte but with time, temp. and substrate the same, the diastatic power of pancreatic amylase is around 4000 (new scale), that of malt amylase about 1570. In the amylase from pancreatin, proteolytic activity is concd. with concn. of the diastatic power, while the purified malt amylase shows no proteolytic activity. The malt prepn. retains its diastatic power much longer in H₂O, the pancreatic product in 50% alc. and when allowed to act upon starch; the rapidity of deterioration is proportional to the purity of the prepn. Heating the dry products to 100° destroys about 1/3 of the activity of the pancreas amylase and 1/2 that of the malt amylase. The rapidity of deterioration in H₂O increases with the temp., this being the more marked with the pancreas amylase. Pancreatic amylase in H₂O is preserved to an important extent by a mixt. of NaCl and NaH₂PO₄ while the deterioration of malt amylase may be hastened by its activating salt (NaH₂PO₄). In long digestion expts. with a large excess of sol. starch (1% soln. with PhMe as antiseptic) at 40°, a malt amylase prepn. produced 2450 times its wt. of maltose in 30 min. and 93,000 times its wt. after 48 hrs., when it ceased to be active, while a pancreas prepn. having the same relative activity, as compared with the most active product, produced 8,000 times its wt. of maltose in 30 min., 440,000 times its wt. in 48 hrs. and 516,000 times its wt. in 96 hrs.; values for other pancreas prepn. are given. Malt amylase deteriorates as much in 1 day at a diln. of 1:10,000,000 as in 10 days at a diln. of 1:10,000. In 50% alc. both amylases are much more stable at 5-10° than at about 23°. Both amylases are essentially proteins, giving the typical color reactions, containing 15-6% N and being hydrolyzed to NH₃ acids; the Van Slyke method shows that the distribution of the N among the NH₂ acid radicals is about the same as in such proteins as edestin and casein. Both are sol. in H₂O and 50% alc., insol. in strong alc. and acetone, show the same colloidal

appearance under the ultramicroscope, are retained by parchment paper and collodion membranes; 1% solns. heated above 50° form ppts. of coagulated albumin, the coagulum giving a violet-blue biuret reaction, while the filtrate gives a biuret reaction which is rose-red in the case of the pancreas, violet-red in that of the malt prepn. The coagulum from 200 mg. of a malt prepn. (equiv. to 0.1836 g. of dry, ash-free substance) in 20 cc. H₂O slowly heated with const. stirring to 50–5°, weighed 0.1136 g. and contained 16.1% N. The filtrate, containing 0.0700 g. of the original substance, contained 0.00959 g. or 13.7% N. A pancreas prepn. gave 11.6% of its wt. of coagulum with 16.9% N while the uncoagulable portion contained 14.9% N. When 200 mg. of a malt amylase prepn. (with a diastatic power of 1470 when fresh and 1050 at the time of the expt.) in 20 cc. H₂O was dialyzed against 200 cc. H₂O at 5–10° for 48 hrs., its activity was reduced to 750; the dialysate showed about 6% of the activity of the original soln. and when added to the dialyzed soln. slightly increased the activity of the latter. The concd. dialysate gave a distinct biuret reaction notably pinker than that of the original soln. but the same concd. dialysate gave no color with ninhydrin. S. and S. conclude that both amylases are complex proteins consisting of an albumin and a proteose (or peptone) fraction, sepd. by hydrolysis when heated in H₂O, the albumin fraction coagulating. In the case of malt amylase, this cleavage appears to be easily reversible, so that the enzyme does not rapidly deteriorate on standing in H₂O, but if the soln. is dialyzed, it does deteriorate rapidly, probably owing to the removal of a cleavage product, and as the dialysate restores the diastatic power only to a slight extent, the dialyzable proteose fraction probably undergoes some further, not readily reversible cleavage in the relatively large amt. of H₂O. With the pancreatic amylase, the cleavage is apparently much less readily reversible, and the proteose fraction may also more readily undergo further cleavage, since the concd. soln. of the non-coagulable portion gives a pinker biuret reaction. In both cases the amylolytic action probably first involves a combination of the amylase with the starch, the labile constituent of the enzyme being protected from destructive change while in such combination.

CHAS. A. ROULLER.

Studies on enzyme action. XIII. The lipase of soy beans. K. G. FALK. New York. *J. Am. Chem. Soc.* 37, 649–53(1915).—The action of lipase from soy beans was studied by methods used for that of lipase from castor beans (cf. *C. A.* 9, 634) and in duodenal contents (cf. *C. A.* 8, 1435). The action of lipase on triacetin in solns. of NaCl, NaF, MgSO₄, MnSO₄, MeOH, and EtOH resembles, in general, that of castor-bean and duodenal lipase. Heat and drying produced effects upon soy bean lipase that were similar to those previously observed for castor bean lipase and esterase. A prepn. of soy bean lipase had practically the same composition as the castor bean product.

W. A. PERLZWEIG.

Enzymes of the central nervous system. H. M. ENGLISH AND C. G. MACARTHUR. *J. Am. Chem. Soc.* 37, 653–64(1915).—Sheep brain contains lipase, erepsin, amylase, catalase, enzymes which decompose arbutin and salol, and probably a pepsin- or trypsin-like enzyme, or both. Lipase and proteases are best extd. with a mixt. of glycerol and H₂O, or with H₂O alone. Exts. of dry tissue were more active than those of fresh tissue, especially after extn. with benzene for removal of lipins. Lipase acted most powerfully upon triacetin and monoacetin; also upon lecithin and cephalin. Its activity followed the laws of enzyme action regarding concn. of enzyme and substrate, and reaction time, having been accelerated by the presence of Na glycocholate, saponin, or a mixt. of Na₂HPO₄ and NaH₂PO₄; it was at its best in a slightly acid medium. Erepsin acts best in an alk. medium. Exts. of gray matter were, in general, more active than those of white. Higher activity was obtained with exts. of cerebrum, cerebellum, and midbrain than with those of medulla, or corpus callosum. Similar amts. of lipase

were found in dog, sheep, beef, human brains, respectively. Negative results were obtained in tests for peroxidase, oxidase, reductase, guanase, urease, rennin. W. A. P.

Identity of heliotropism in animals and plants. I. JACQUES LOEB AND HARDOLPH WASTENREYS. *Proc. Nat. Acad.* 1, 44-7(1915).—The different parts of the spectrum of a carbon arc light are shown to exercise the same relative efficiency in the production of heliotropic responses in the animal *Eudendrium* (polyps) as in the seedlings of the plant *Avena*. II. *Science* 41, 328-30(1915).—Two types of heliotropic (biological) substances are suggested; one with the max. of sensitiveness or absorption in the yellowish green, near $\lambda = 534 \mu$, and the second with the max. of sensitiveness in the blue, near $\lambda = 477 \mu$. Both of these types are distributed in both animal and plant kingdoms, independently of systematic boundaries. W. A. PERLZWEIG.

Biochemical systems and their role in the development of the organism. W. BECHTEREW. *Rev. gen. sci.* 25, 770-7(1914).—Discussion of the interdependence of factors in heredity and evolution, and of biochemical systems such as the internal secretions. W. A. P.

Nature of antagonism. W. J. V. OSTERHOUT. Harvard Univ. *Science* 41, 235-6(1915).—The author attempts to explain the antagonism of both electrolytes and non-electrolytes on the basis of their opposite effects on protoplasm. He reaches this conclusion from his studies on the effects of substances on the permeability of protoplasm. For a description of these expts. cf. *C. A.* 6, 2438; 9, 327. W. A. P.

Biochemical research of glucosides hydrolyzable by emulsin in some plants of Papilionaceae and Scrophularineae. E. BOURQUELOT AND A. FICHTENHOLZ. *J. pharm. chim.* 11, 219-25(1915).—By observing the optical rotation upon the successive action of invertin and emulsin on solns. of the various exts., and detg. the % of reducing sugar formed, the presence of glucosides was indicated in *Cytisus laburnum*, *Ononis natrix*, *Psoralea bituminosa*, *Indigofera leptostachya*, *Scrophularia aquatica*, *Linaria spuria*, *L. elatine*, *L. cymbalaria*, *L. vulgaris*, *L. purpurea* and *Euphrasia officinalis*. Only 2, *Coronilla varia* (Legum.) and *Melampyrum arvense* (Scroph.) gave no indication of glucosides. The sugars are cane sugar, except that in *Linaria spuria*. *Linaria* is especially rich in glucosides. (Cf. *C. A.* 1, 767; 5, 514). S. WALDBOTT.

Physico-chemical research on the animal liquids. IX. The curve of the neutralizing power of urine. G. QUAGLIARIELLO AND E. D'AGOSTINO. Univ. Naples. *Atti accad. Lincei* 23, II, 638-45(1914).—The effect on the conc. of H ions of the addition of increasing amts. of HCl and NaOH was detd.: (1) in urine of a normal man; (2) in synthetic urine (an aq. soln. of Na_2HPO_4 , KCl, CaCl_2 , MgSO_4 , H_2SO_4 , NaOH, HCl, Na urate and urea); (3) in 0.05 N KH_2PO_4 . The log. of the H ion conc. is plotted against the amt. of HCl or NaOH added. The neutralization curves obtained in (2) and (3) are quite different from those obtained in (1). In both (2) and (3) there is a marked critical point. Q. and A. ascribe this difference to the presence in natural urine of a phosphoric-uric acid complex, which is not formed in synthetic urine. The lower dissociation const. of the complex acid explains the higher neutralizing capacity of the natural as compared with synthetic urine. E. J. WITZEMANN.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

The simplest and quickest demonstration of iodine in urine, saliva and in other body fluids. I. SCHUMACHER. *Deut. med. Wochschr.* 41, 196-7(1915).—A tablet of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ is placed on a piece of filter paper and 5 to 7 drops of the fluid to be examd. are added. If iodides are present, I is set free and stains the cellulose of the paper blue. Even some I in organic combination is liberated. S. AMBERG.

Simple method of quantitative urea determination in small amounts of blood for the purpose of diagnosis of kidney lesions. A. HAHN. *Deut. med. Wochschr.* 41, 134-6(1915).—Further simplification of the previous method of Hahn and Saphra (cf. *C. A.* 8, 2172) for the detn. of urea in urine. A very small amt. of a dry prepn. of soy urease is used (0.015-0.02 g.). One cc. urine is measured into a 50 cc. flask and to this 10 cc. water and 2 drops methyl orange are added. This is titrated immediately with 0.1 *N* HCl to change the indicator to orange yellow, not red. Then a small amt. of enzyme and 3 drops of toluene are added, whereupon the flask is well stoppered and left standing until the next day, when it is titrated with 0.1 *N* HCl. One cc. 0.1 *N* HCl corresponds to 3 mg. urea. The urea in blood is detd. as follows: One cc. serum is placed in a flask and 20 cc. water, a little enzyme and 3 drops toluene (not more) are added. In a second flask are placed 1 cc. serum, 10 cc. water and toluene. Both flasks are stoppered and left standing 8-20 hrs. at room temp. The contents of each flask are now treated in the same manner, i. e., 20 cc. 0.1 *N* HCl are added and the fluid transferred to a 150 cc. flask with distd. water. 0.5 cc. of a 5% KIO₄ soln. and some KI are added and the soln. shaken well. The yellow I color must now appear. 20 cc. 0.01 *N* thiosulfate soln. are run in and then 2 cc. 1% starch soln. This soln. is titrated with 0.1 *N* I soln. The change from a whitish turbidity to green is sufficiently sharp. The difference between the I added to flask I and II gives the alkalinity derived from the urea, and needs only to be multiplied by 0.0003 to obtain the urea in 1 cc. serum. S. AMBERG.

Color reaction of gallic acid and tannic acid and its application. C. T. MÖRNER. *Pharm. Zentralkalle* 56, 13(1915).—Priority is claimed for Griessmyer (*Z. anal. Chem.* 11, 43(1872)) in the matter of the reaction described by Schewket (cf. *C. A.* 8, 327, 723). C. O. EWING.

The use of formalinized blood corpuscles in the complement fixation test. W. PFREILER AND K. LOSSOW. *Mitt. Kaiser Wilhelms Inst. Landw. Bromberg* 5, 276-80 (1913); through *Exp. Sta. Rec.* 30, 779.—Blood corpuscles should be treated in an unwashed state with HCHO and then kept on ice, or at room temp., and washed when required for use. E. M. FRANKEL.

The diagnosis of plague by means of the precipitin test of Ascoli. H. BERLIN. *Centr. Bakt. Parasitenk., Abt. I* 75, 466-85(1915).—An ext. made by boiling in NaCl soln. the organs of an animal infected with plague, artificially or naturally, will give a ppt. with plague antiserum. The reaction is positive with exts. of either fresh or putrid organs from infected animals. The amt. of ppt. depends on the amt. of plague bacilli in the organs. In making the test, undild. serum and exts. should be used. The reaction is not specific as it is sometimes given with normal organ extracts. It is positive if the infected organs have remained in formalin or alc. for a long time. This test should not replace the bacteriological test, but should be used as an aid to it. J. H. L.

Convenient methods for demonstrating the biochemical activity of microorganisms, with special reference to the production and activity of enzymes. C. H. CRABILL AND H. S. REED. *Va. Agr. Expt. Sta. Biochem. Bull.* 4, 30-44(1915).—Descriptions are given of methods, adapted to the needs of the class room, for making semi-permanent demonstrations of the activities of microorganisms. "The methods are designed to show the presence and action of products of cellular activity upon appropriate substances incorporated in thin layers of agar in Petri dishes." Methods have been devised to show the presence of amylase, emulsin, lipase, proteases, erepsin, trypsin, amidase and cytase, and for the formation of lactic or other acids. A. P. LOTHROP.

Role of serum antitrypsin in the Abderhalden test. J. BRONFENBRENNER, W. J. MITCHELL, JR. AND PAUL TITUS. *West. Penn. Hosp., Pittsburgh. Biochem.*

Bull. 4, 86(1915).—The appearance of dialyzable cleavage products in the serum is dependent upon "the removal of serum antitrypsin, which in turn liberates the normal proteases of the serum, thus setting the serum into autodigestion." The anti-tryptic activity of serum, as tested against trypsin soln., diminishes in a sp. manner in serum of pregnant individuals so that the estn. of antitrypsin may be used as a method of diagnosis of pregnancy parallel with or complementary to the Abderhalden test.

A. P. LOTHROP.

The estimation of lipid and acid-soluble phosphorus in small amounts of serum. ISIDOR GREENWALD. Harriman Research Lab., N. Y. *J. Biol. Chem.* 21, 29-36 (1915).—The method depends upon the formation of finely suspended strychnine phosphomolybdate, which is yellow in color when placed in a colorimeter. Measure 1 cc. of serum into a 10 cc. volumetric flask, containing about 8 cc. of 1% picric-1% acetic acid mixt. and make up to the mark with the same soln. The serum must be free from hemoglobin. Allow to stand 2 hrs. with occasional shaking and filter through a 5.5 cm. No. 589 black ribbon C. S. & S. filter paper into a standard 10 cc. cylinder. Read the vol. of the filtrate, transfer to a Jena test tube, 200 x 20 mm.; add a few glass beads and boil down to 1 cc. Add 1 cc. concd. H_2SO_4 and heat until all the picric acid has been distd., heating the sides of the tube to insure complete removal. Complete the oxidation by adding 1-2 drops of concd. HNO_3 and heating. The residue and filter paper (lipoid P) are transferred to another test tube and oxidized by adding 1 cc. of H_2SO_4 and as much HNO_3 as is necessary. Cool, dil. and almost neutralize with 10% NaOH (from Na). Make up to 50 cc. and take aliquot portions, usually 20 and 10 cc., for the detns. Measure these amts. into 50 cc. volumetric flasks, add 5 cc. of dil. HNO_3 (35 cc. concd. HNO_3 dild. to 100 cc.) and dil. to about 45 cc. Mix thoroughly and add 2 cc. of the reagent of Pouget and Chouchak. ((A) Dissolve 95 g. of molybdic acid and 30 g. of dry Na_2CO_3 in 600 cc. warm H_2O , cool, add 141 cc. concd. HNO_3 and dil. to 1000 cc. (B) Dissolve 2 g. of strychnine sulfate in 90 cc. warm H_2O and dil. to 100 cc. For use, add 1 cc. of B to 10 cc. of A, filter and use at once.) Make up to 50 cc. and mix. At the same time measure 5 cc. of a soln. containing 0.0131 mg. P (0.03 mg. P_2O_5) into another flask and treat similarly. Allow to stand 20 mins. and compare the colors in a Dubosq colorimeter, setting the standard at 80 mm. In calcg. the results make proper correction for the vol. of soln. adhering to the protein-picric ppt. The error is about $\pm 2\%$. The amt. of P not pptd. by the acetic-picric acid mixt. varies in normal individuals between 2 and 6 mg. per 100 cc. of serum, apparently depending on the diet and stage of digestion. The amt. of lipoid P is usually from 7 to 13 mg. per 100 cc. and is less subject to variation in the same individual than is the amt. of acid-sol. P. In nephritis there is retention of inorganic PO_4 and an increase in the amt. of lipoid P in the serum.

A. P. LOTHROP.

The estimation of non-protein nitrogen in blood. ISIDOR GREENWALD. Harriman Research Lab., N. Y. *J. Biol. Chem.* 21, 61-8(1915).—The use of CH_3OH for the pptn. of proteins as recommended by Folin and Denis (*C. A.* 7, 1209) in their method for the detn. of non-protein N in blood is open to the objection that added amino acids cannot be quant. recovered in the filtrate and that it exts. also a certain amt. of lipoid N which, although non-protein, does not belong in the same fraction as urea and amino-acid N. When a 2.5% CCl_3CO_2H soln. is substituted for CH_3OH as proposed by G., the lipoids are completely pptd. with the proteins, added amino acids can be quant. recovered and the final filtrate, free from protein, contains all the H_2O -sol., non-protein blood constituents. The method is as follows: dil. blood to 10 times its original vol. with 2.5% CCl_3CO_2H soln., filter after 30 min., shake the filtrate with about 4 g. of kaolin per 100 cc. and filter again. Measure portions of the filtrate into large Jena test tubes, add a few glass beads, 1 cc. of concd. H_2SO_4 and a few drops of 5% $CuSO_4$.

soln. and boil down until the mixt. chars. Add about 0.3 g. K_2SO_4 and heat 5 min. after the mixt. is colorless. Cool, dil., add a little powd. pumice and distil as recommended by Bock and Benedict (*C. A.* 9, 813). Proceed subsequently according to the method of Folin and Denis. It is most convenient to use 10 cc. of filtrate, equiv. to 1 cc. of blood, and to dil. the distillate, after Nesslerizing, to 50 cc. Using this method G. has found the normal amt. of non-protein N in human blood to be about 30 mg. per 100 cc. instead of about 22 mg. It appears that a considerable amt. of non-protein N normally present in blood, the nature of which is yet to be detd., is not extd. when CH_3OH is used as the protein precipitant.

A. P. LOTHROP.

A note on the determination of nitrogen by the Kjeldahl-Folin-Farmer method. VICTOR J. HARDING AND FRANCIS H. S. WARNEFORD. McGill Univ. *J. Biol. Chem.* 21, 69-71(1915).—While the Folin-Farmer method is satisfactory for the detn. of total N in minute amts. in physiological fluids, the inherent errors are too large to allow its use in detg. the % of N in small amts. of organic compds. and the calcn. of formulas therefrom.

A. P. LOTHROP.

Gastrointestinal studies. VIII. A method for the quantitative estimation of trypsin in the gastric contents. WILLIAM H. SPENCER. Jefferson Med. College. *J. Biol. Chem.* 21, 165-7(1915).—Prepare 5 reagent tubes, Nos. 1, 2, 3, 4 and 5. Add to tubes 1 and 2, 0.5 cc. of gastric contents, which have been filtered if turbid. To tubes 2, 3, 4 and 5 add 0.5 cc. distd. H_2O . From tube 2 remove 0.5 cc. and add to tube 3. Mix and transfer 0.5 cc. from tube 3 to tube 4. Repeat for tube 5. This gives dilns. of gastric contents of 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ and $\frac{1}{16}$. To each tube add 1 drop of a 1% alc. soln. of phenolph., and drop by drop 2% $NaHCO_3$ until a light pink color is produced. Add to tubes 1, 2, 3 and 4, 0.5 cc. of casein soln. and to tube 5, 1 cc. (Prepare the casein soln. by dissolving 0.4 g. of casein in 40 cc. 0.1 *N* $NaOH$. Add 130 cc. of distd. H_2O and 30 cc. of 0.1 *N* HCl). Incubate the tubes at 40° for 5 hrs. Ppt. the undigested casein by adding drop by drop a soln. containing 1 cc. of glacial $AcOH$, 50 cc. of 95% alc. and 50 cc. distd. H_2O . The tubes in which digestion is complete remain clear; a turbidity appears in the others. The tryptic values are expressed in terms of diln., complete digestion in a diln. of $\frac{1}{4}$ for example indicating a tryptic value of 4. Controls of boiled gastric contents must show no digestion and become turbid on addn. of the pptg. soln.

A. P. LOTHROP.

Note in defense of the Folin-Farmer method for the determination of nitrogen. OTTO FOLIN. Harvard Med. School. *J. Biol. Chem.* 21, 195-9(1915).—F. discusses the recent criticisms by Bock and Benedict (*C. A.* 9, 813) of the original Folin-Farmer method. When the air supply for aeration comes from out of doors, no NH_3 is obtainable in blank tests. If lab. air is employed a possible source of error may be introduced. Errors due to traces of NH_3 in the H_2SO_4 and K_2SO_4 apply with nearly equal force to the Kjeldahl method. If the Ostwald pipet is used explicitly as described, the error is only about 0.1%, not 1% or over as claimed by Bock and Benedict. Colorimetric readings are subject to the "personal equation" and may amount to 1%. Experience and const. use, however, reduce the error to considerably less than 1%. Titration with 0.02 *N* $NaOH$, using methyl red as indicator, can be substituted for the colorimeter by those who cannot readily learn to use that instrument with accuracy and certainty.

A. P. LOTHROP.

Creatinine and creatine determinations. The occurrence of creatine. J. L. MORRIS. Washington Univ. *J. Biol. Chem.* 21, 201-8(1915).—A method has been devised for the detn. of creatinine and creatine in the presence of acetone, acetoacetic acid or glucose; it is much more rapid than the methods involving extn. and distn. The creatinine is pptd. as the double salt of K and creatinine, the ppt. is redissolved and the creatinine value of the soln. detd. To 100 cc. of urine add 1 g. of picric acid and

warm to not more than 60° on a H₂O bath to hasten the soln. of the picric acid. Cool, stir well and allow to stand 4 hrs. Decant through a Gooch crucible and return to the beaker the ppt. caught on the asbestos. Dissolve the double salt by heating on a H₂O bath with 100 cc. of 0.5 N HCl, transfer to a 500 cc. volumetric flask and make up to the mark with hot H₂O used in rinsing the beaker. Filter a portion from asbestos and det. the creatinine in a 10 cc., 5 cc. or smaller amt. of soln. which gives a value nearest a 1 mg. standard. Use as a standard a soln. of K creatinine picrate containing 1 mg. of creatinine per 10 cc. (0.5388 g. of the double salt in 1000 cc. 0.1 N HCl). In detg. *crealine*, add to 100 cc. of urine 20 cc. of 5 N HCl and heat in an autoclave at 120° for 40 mins. Neutralize the HCl with 10% NaOH. Make up to 200 cc., filter and use 100 cc. of the filtrate for pptn. of the K creatinine picrate. Add 1.5 g. of picric acid, hastening soln. by heating over a free flame, and allow to stand overnight. Complete the detn. as already described. *The pptn. is not complete in either case and a correction of 8 mg. should be added in each detn. of creatinine and one of 12 mg. in the creatinine-creatinine detn.* The method should *not* be used for general routine work but possesses a distinct advantage when interfering substances are present. That the creatine appearing as an additional amt. of creatinine after hydrolysis is really such and not some other substance converted into a form giving the color reaction, is shown by the fact that this resultant "creatinine" is pptd. as the double picrate under the same quant. conditions as is creatinine. The identity of the creatine reported in the urine of children, post partum women, diabetics and fasting individuals is thus established.

A. P. LOTHROP.

New technic for the administration of "606." F. NARBONA. *Gac. farm. españ.*; *Boll. chim. farm.* 53, 10(1914).—Five-tenths cc. pure MeOH and the desired amt. of "606" are carefully mixed in a mortar; 4–6 cc. (according to the amt. of "606" employed) of physiol. serum are then added. This method of administration assures absence of inflammation and supuration.

H. S. PAINE.

Simplification of the hemin crystal test. NIPPE. *Boll. chim. farm.* 53, 139(1914).—A soln. is prepd. from 0.1 pt. KBr, 0.1 pt. KI, 0.1 pt. KCl and 100 pts. glacial AcOH. Several drops of this soln. are added to the blood sample and the latter is heated on a glass slide with cover disk until bubbles are formed. Crystals may then be observed with the low power of the microscope. Excess of the soln. may be removed by evapn. or aspiration.

H. S. PAINE.

Sterilization of phosphate sera. GUYOT. *Giorn. farm. chim.* 53, 72(1914).—Cheron phosphate serum gives a slightly alk. reaction to litmus and cochineal and is rendered turbid by the action of heat; this turbidity may be prevented by the addition of acid. G. recommends the addition of 8 drops official H₃PO₄ to 100 cc. Cheron serum. The latter prep. then remains clear after sterilization and may be injected into tissues without producing irritation or inflammation.

H. S. PAINE.

Determination of acetone in urine. L. SOBEL. *J. suisse pharm.*; *Giorn. farm. chim.* 63, 470(1914).—The method of Lieben which consists in isolation of the Me₂CO by distn. and estn. by means of the formation of CHI₃ has been rendered exact by S. Add several cc. HCl to 200–250 cc. urine and distil through a Liebig condenser; treat the distillate with KI and K₂CO₃; collect the ppt. of CHI₃ on a filter and carefully wash with H₂O until the filtrate fails to give a ppt. with AgNO₃; place the CHI₃ with the filter in a flask with fuming HNO₃ and several crystals of AgNO₃ and bring to boiling under a reflux condenser. After suitable diln. the AgI thus formed is collected on a filter, washed, dried and weighed. The wt. of AgI multiplied by 0.1171 gives the wt. of Me₂CO.

H. S. PAINE.

A micro-method for the determination of freezing points. ERLING SCHREINER. *Tidsskrift Kem. Farm. Terapi* 12, 69–72(1915).—The operation is conducted in a

Dewar flask (10 x 18 cm. inside), which contains a 20% soln. of glycerol. Into this is inserted a condenser through which circulates NaCl soln. A ring stirrer encircles the condenser and is moved up and down at 20 to 60 strokes per min. Outside the stirrer a thermometer is inserted into the glycerol and to this is attached the capillary tube containing the sample to be examd. The sample is frozen and allowed to melt by slowly increasing the temp., and the formation of the meniscus noted. A detn. can be accomplished in $\frac{1}{2}$ hr. The vol. required for the detn. need not exceed 0.005 cc. A table gives the results of examns. of 12 salt solns. and 2 sera. These results were compared with similar detns. in the usual Beckmann app.; 7 of them were identical. The max. discrepancy was 0.02°; this difference was observed in both salt and serum samples.

ERNEST D. CLARK.

Reduction and alcoholic fermentation. HERBERT STANGE. Univ. Leipzig. Z. Gärungsphysiol 5, 65-150(1915).—The reducing power of yeast juice was tested with a number of reducible substances. At the beginning of fermentation reducible substances in moderate concn. may have a stimulating effect (methylene blue) or an inhibiting effect (selenious acid). In 0.1 mol. conc. all reducible substances are strongly inhibitory, especially tellurate, thiosulfate and methylene blue. Selenious acid and selenite exert an extraordinary depression. The fermentation quotient, $C_2H_5OH:CO_2$, is invariably lower than that corresponding to the theoretical equation. This change is brought about by an increased production of CO_2 , the absolute value of which is identical for exts. of the same dried yeast prepn. In the presence of S and TeO_2 , both of which depress the total fermentation only slightly, no change in the quotient in the sense of the Grüss and Kostychev theory was observed. The amts. of reduction product are extremely small in comparison to the fermentation, especially with S and thiosulfate. The reduction of telluric acid is proportional to the concn. and to the vigor and the time of fermentation. The reducing power of non-fermenting juice is attributed to the proteolytic process, since addition of telluric acid increases the CO_2 production. Quantitatively considered, reduction is an insignificant concomitant phenomenon of alcoholic fermentation and proteolysis. The assumption of a reducing ferment has no experimental basis.

A. W. DOX.

Influence of the radioactivity of the air on the microorganisms of the atmosphere. A. TRILLAT AND FOUASSIER. Compt. rend. 159, 817-9(1914). E. M. FRANKEL.

Organic nutrition of a marine bacterium. H. COUPIN. Compt. rend. 160, 151-2 (1915).—*Micrococcus spumaeformis* does not grow on gelatin media containing pure water but thrives if 2.5% of NaCl is added. It easily assimilates glucose, fructose, galactose, sucrose, maltose, glycerol, mannitol, glycogen and peptone, whereas tyrosine, glycocoll and fatty substances are only poorly used. The organism does not utilize lactose, starch, dextrin, inulin, egg-white, primary alcs., glycol, erythrol, formaldehyde or organic acids. It ferments glucose, galactose, fructose, sucrose, lactose, EtOH, glycerol and mannitol. In general it requires sugar and peptone for its nutrition.

E. M. FRANKEL.

Marine yeast. H. COUPIN. Compt. rend. 160, 251-2(1915).—Marine yeast, *Torula marina*, may be cultivated in fresh water containing peptone or glucose, or on

gelatin, potato, or carrots, but its fermentation is not as marked as when it is grown on sea-water media. E. M. FRANKEL.

Factors which influence the development of *Penicillium glaucum*. Contributions to the knowledge of antiseptics and narcotics. H. J. WATERMAN. Delft. *Centr. Bakt. Parasitenk., Abt. II* 43, 639-88(1915). J. H. LEWIS.

Development of alkalinity in *Glomerella* cultures. HOWARD S. REED AND J. T. GRISOM. Va. Agr. Expt. Sta. *J. Biol. Chem.* 21, 159-63(1915).—The fungus used was *Glomerella rufomaculans*, the cause of the bitter rot of apples. The alkalinity developed in the culture medium is due to the formation of (a) carbonates, (b) NH_3 , and (c) organic bases. The carbonates probably arise from the combination of Na^+ , K^+ and NH_4^+ with the CO_2 formed by fermentation of the carbohydrate in the culture medium. The NH_3 is formed by the autolysis of the fungus protein rather than by denitrification. Bases of the hexone and purine series are also developed as a result of autolysis of the fungus protein. A. P. LOTHEP.

Quantitative determination of sulfur in the culture medium for the detection of the bacteria producing hydrogen sulfide. H. W. REDFIELD AND CLARENCE HUCKLE. Cornell Univ. *J. Am. Chem. Soc.* 37, 612-23(1915).—Using the methods described in another paper (cf. *C. A.* 9, 1069) for the estn. of S in peptone, the authors studied (a) the total amt. of S broken down by putrefactive bacteria in an unadjusted culture medium contg. 3% Witte peptone and 0.75% KCl, (b) the forms of S most readily used by these bacteria, and (c) the forms resulting from their activity. W. A. P.

Germicidal power of glycerol on various microorganisms under various conditions. E. H. RUEDIGER. *Philippine J. Sci.* 9B, 465-77(1914).—R. states that glycerol has a distinct, though feeble germicidal action, the latter being weaker at 15° than at $30-5^\circ$. Germicidal action also depends on the diluent; the microorganisms died sooner in glycerol dild. with physiol. salt soln. than in glycerol diluted with bouillon or horse serum. In dild. up to 50%, glycerol failed to destroy the anthrax organism in 15 days. This may be due to presence of resistant spores. Glycerol appears to act as a selective poison upon plague, cholera and diphtheria organisms. All the non-spore-forming organisms died in less than 4 days in 50% glycerol-physiological salt soln. W. A. P.

Antiseptic role of some insoluble substances. LOUIS RÉNON, CH. RICHET FILS AND ANDRÉ LEPINE. *Compt. rend. soc. biol.* 76, 64-6(1914).—The antiseptic action of electrically produced colloidal C (the size of the particles being approx. $4-6 \mu\mu$) was measured by means of its retarding action on the acidification of milk by the lactic acid bacillus. The colloidal C exerted an undeniable antiseptic action which increased with the amt. of C present, the latter acting in this respect as an ordinary antiseptic. No acceleration of the action of the lactic acid bacilli by minimal amts. of colloidal C was detected, this being contrary to the observation of Richet in the case of chem. antiseptics. H. S. PAINE.

Exchange of nutrients in plants. P. MAZÉ. *Compt. rend.* 159, 809-11(1914).—Chem. activity of living protoplasm regulates the relations of the cell to the exterior, independently of the laws of osmosis. E. M. FRANKEL.

Experiments on the pigments of the chromoleucites. V. LUBIMENKO. *Compt. rend.* 160, 277-80(1915); cf. *C. A.* 8, 1602.—The transformation of chloroleucites into chromoleucites involves the formation, by oxidation and reduction, of a number of

pigments resembling carotin and xanthophyll, and their isomers lycopin and rhodoxanthin. E. M. FRANKEL.

Free nitrogen and the higher plants. M. MOLLIARD. *Compt. rend.* 160, 310-3 (1915).—Higher plants, like the radish, do not utilize atmospheric N. E. M. F.

Carbon nutrition of horticultural plants. H. FISCHER. *Gartenflora* 63, 125-32 (1914); *Exp. Sta. Rec.* 31, 532.—Excess of CO₂ in the air materially increases the yield of fruit and flowers over the normal. E. M. FRANKEL.

Studies on the physico-chemical properties of vegetable saps. III. A comparison of the physico-chemical constants of the juices expressed from the wall with those from the included carpellary whorl in proliferous fruits of *Passiflora gracilis*. J. A. HARRIS AND ROSS A. GORTNER. *Carnegie Inst. Biochem. Bull.* 4, 52-79(1915).—Detns. were made of sp. gr., concn., depression of f. p., osmotic pressure, elec. cond., and mean mol. wt. of the cell sap from the tissues of the wall and the abnormal carpellary whorl of fruits with trimerous fruit wall and tetramerous proliferation. Sixty samples of this class were obtained by the dissection of about 100,000 fruits of *Passiflora gracilis*. The physico-chem. constns. are all susceptible to the influence of the environmental and possibly to the physiological state of the plant upon which the fruit is borne. The sp. gr., concn. (wt. of solutes/wt. of H₂O), sp. elec. cond. and osmotic pressure are all higher in the sap of the fruit wall than in that from the carpellary whorl. The concn. of electrolytes is relatively higher in the fruit wall while that of nonelectrolytes is higher in the sap of the proliferation. The mean mol. wt. of the solutes is quite variable but apparently is somewhat higher for the solutes of the abnormal tissues. The paper is limited to the presentation of facts; no attempt is made to discuss the physiological significance of the results. A. P. LOTHROP.

Digestibility of rations for steers. H. W. MUMFORD, H. S. GRINDLEY, L. D. HALL AND A. D. EMMET. *Univ. Ill. Agr. Expt. Sta., Bull.* 172, 235-78(1914).—Results are given relating to the effect, in steers, upon the coeffs. of digestibility (1) of variations in the proportions of roughage and concentrates in the ration, (2) of the substitution of a nitrogenous concentrate for a part of the grain in the ratio of 1:5, and (3) of variations in the amt. of feed consumed from maintenance rations to full feed. W. A. PERLZWEIG.

Forms of nitrogen in growing pigs, with special reference to the influence of the quantity of protein consumed. W. E. JOSEPH. Univ. Ill. Agr. Expt. Sta., *Bull.* 173, 289-317(1914).—No difference was observed in the nature of the nitrogenous material produced in growing pigs, on varying the quantity of protein consumed between 0.32 and 0.94 lb. per 100 lbs. of live wt. Only the character of the body proteins remains unchanged, the amt. of these being affected, when the supply of food-protein is deficient.

W. A. PERLZWEIG.

ABNORMAL.

Ratio between amino nitrogen and total nitrogen in the urine of those sick with croupous pneumonia. E. SIGNORELLI. Inst. for advanced studies, Florence. *Lo sperimentale* 68, 117-131(1915).—The ratio amino N:total N is in general 0.01-0.02 notwithstanding the alterations of the exchange which is produced in the pneumonics. In the crisis of the disease the urine shows a large amt. of N, and after the crisis a gradual increase of total N. At the crisis there is a greater endogenous production of NH_3 acids, but the equil. between the NH_3 acids is destroyed and their concn. in the blood is not altered. This is probably the cause of the constancy of the ratio. In one case which failed to bear out the above conclusions severe albuminuria was observed; this would introduce an inaccuracy in the NH_3 acid detns. by the Henriques-Sørensen method.

H. W. BANKS, 3RD.

Change in amino acids during fasting. A. FRANCESCO. Lab. of the Italian Hospital, Buenos Ayres. *Lo sperimentale* 68, 137-44(1915).—In dogs under normal conditions on a mixed diet sufficient to maintain const. body wt., a nearly const. amt. of amino acids was eliminated. The ratio amino N: total N has an individual value (const. within certain limits) for each animal. During fasting to the point of exhaustion and death of the animal the ordinary oscillations in the % of NH_3 -N were observed. The av. over the whole period was, however, greater than under normal conditions. This increase was most noticeable toward the end of the period. F. concludes, therefore, that splitting of proteins, especially during the last days of fasting, undergoes appreciable modification.

H. W. BANKS, 3RD.

Analyses of the urine of a man during a two-week fast. R. WATANABE AND R. SASSA. Tokio. *Z. Biol.* 64, 373-408(1914).—Minimum N output was reached in the second week (0.18-0.20 g. per kg.). There was a steady increase in the ammonia N, and total acidity. The uric-acid-N diminished at first and then rose towards the end. The purine-N remained const., while the creatinine-N ran parallel to the total N in a ratio of 1:7.1. The Cl output diminished steadily. The N:P₂O₅ ratio was quite high (5.8:1). The mol. diuresis ($\Delta \times$ urine vol.) increased up to the 4th day and then diminished.

E. M. FRANKEL.

A case of levulose in urine. ED. JUSTIN-MUELLER. *J. pharm. chim.* 11, 218-9 (1915).—A certain specimen reduced Fehling soln., but showed negative optical rotation. Levulose was plainly indicated by the dark red ppt. with Selivanov's reagent. The sample of urine was taken in a case of indigestion due to overeating of raisins and figs. Another sample from the same person showed no trace of sugar.

F. PHYSIOLOGY.

ANDREW HUNTER.

The relation between the efficiency, gaseous exchange and food consumption of the mammalian heart. E. ROHDE AND NAGASAKI. Heidelberg. *Zentr. Physiol.* 27, 1114-22(1914).—Normally O consumption bears a direct relation to the work done. In disturbances due to narcotics, lack of O, CO poisoning, muscarine, veratrine, etc., the work diminishes more rapidly than the O consumption. Every diminution of energy exchange is accompanied by a rise in carbohydrate metabolism and lowering of metabolism of protein and fat, the former effect being primary while the latter is secondary. Diminished oxidation due to lack of O or to KCN results in appearance of organic acids and aldehydes. Parallel with these disturbances in carbohydrate metabolism there is depression in the ratio of the O consumption to work. This cannot be referred to modified sugar metabolism for, in CO₂ poisoning sugar metabolism does not change while the ratio of O consumption to work is depressed. R. and N. believe impaired energy relations are due to increased H ion concn. in the muscle cells.

E. M. FRANKEL.

Studies on the physiology of reproduction in the domestic fowl. XIII. The failure of extract of pituitary body (anterior lobe) to activate the resting ovary. RAYMOND PEARL AND FRANK M. SURFACE. Maine Agr. Expt. Sta. *J. Biol. Chem.* 21, 95-101(1915).—On account of the well established connection between the pituitary body and the genital organs, the effect of injection of exts. of the anterior lobe of the pituitary of the cow on the resting ovary was studied. The autumn moulting period was chosen for the study as that is the only long-continued and certain period of true physiological rest of the ovary. The birds were all normal, healthy, yearling fowls in the process of moulting at the end of their first or pullet laying year. The injection of pituitary ext. "into the abdominal cavity of hens in which the ovary is in a completely resting condition did not cause an activation of the ovary, in the sense of inducing ovulation at an earlier date than that at which it would normally occur."

A. P. LOTHROP.

Changes in the blood after muscular activity and during training. E. C. SCHNEIDER AND L. C. HAVENS. *Am. J. Physiol.* 36, 239-59(1915).—Exercise causes a rapid increase in hemoglobin, erythrocytes, leucocytes, and sp. gr. of the blood. Evidence is presented indicating that the erythrocytes are called out from an abdominal store perhaps through the action of epinephrine. The leucocytes are squeezed out of the tissues by the muscular movements.

J. F. LYMAN.

Influence of blood transfusion on the kidneys. I. A. RABENS. *Am. J. Physiol.* 36, 294-8(1915).—Detns. of urinary total N, urea, NH₃, amino acids, P, Cl, reducing sugars, acidity and sp. gr. with normal and depancreatized dogs before and after transfusions of normal blood do not give any evidence of injury to the kidneys by the method of transfusion. Dogs excrete only 10 to 14% as much chlorides following pancreatectomy as before the operation, the diet remaining constant.

J. F. LYMAN.

Distribution of gastrin in the body. R. W. KEETOM AND F. C. KOCH. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 353(1915).—Gastrin, a hormone having a stimulating action on the gastric glands, was prepd. from pyloric and fundus portions of the stomach and in lower concs. from cardiac portions, intestinal mucosa and esophagus. In other tissues its presence could not be demonstrated.

J. F. LYMAN.

Relation of red corpuscles and the hemoglobin to the oxygen tension of the respired air. H. C. DALLWIG, A. C. KOLLS AND A. S. LOEVENHART. *Proc. Am. Physiol.*

Soc.; Am. J. Physiol. 36, 356-7(1915).—When O tension of respired air is reduced below 14% of an atm., red corpuscles and hemoglobin increase after 3 to 7 days due to increased activity of the bone marrow. J. F. LYMAN.

Influence of depancreatization upon the state of glucemia following the intravenous injection of dextrose in dogs. I. S. KLEINER AND S. J. MELTZER. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 361-2(1915).—After intravenous injections of dextrose (4 g. per kg.) into depancreatized dogs blood sugar does not return to its former value in 1.5 hrs. as it does with normal animals. J. F. LYMAN.

Apnea as an after-effect of pulmonary distension, and its dependence on the vagus nerves. T. S. GITHENS AND S. J. MELTZER. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 363(1915).—Apnea may be produced by the mere distension of the nerve endings of the pulmonary vagus without the aid of a chem. factor (acapnia), even when the air used for distension contains 5% CO₂, provided the vagus nerves are intact. J. F. LYMAN.

Changes in the content of hemoglobin and red corpuscles in the blood of man at high altitudes. E. C. SCHNEIDER AND L. C. HAVENS. *Am. J. Physiol.* 36, 380-97 (1915).—Comparative effects of abdominal massage and exercise at different altitudes on hemoglobin and red corpuscle content of the blood in peripheral vessels indicate that the rapid increases observed during the first 2 or 3 days spent at a high altitude are due in part to the throwing into the general circulation of a large mass of reserve corpuscles from the abdominal area and in part to a loss of fluid from the blood. Blood-forming centers also become more active at high altitudes. J. F. LYMAN.

Effect of partial adrenal deficiency upon sympathetic irritability. R. G. HOSKINS. *Am. J. Physiol.* 36, 423-9(1915).—The removal of 0.5 to 0.7 of the adrenal tissue in the dog resulted in a depressed irritability of the sympathetic nervous system as shown by low blood pressure, decreased vasomotor reaction to nicotine, and unchanged reaction to epinephrine. J. F. LYMAN.

Action of glandular extracts on the secretion of cerebrospinal fluid. C. H. FRAZIER AND M. M. PERT. *Am. J. Physiol.* 36, 464-87(1915).—Saline exts. of pancreas, spleen, kidney, liver, ovary and testes do not influence the rate of secretion of the choroid plexus. An apparent increased rate is due to mechanical rather than secretory effects in that the fall in arterial blood pressure following injections of the exts. increases pressure in the cranial venous sinuses, thus forcing out preformed fluid in the ventricles and cisterna magna. Brain exts. cause a secretion independent of blood pressure. Thyroid exts. have a specific inhibitory effect. J. F. LYMAN.

Researches on the perfused heart. Some effects of sodium chloride. W. BURRIDGE. Oxford. *Quart. J. Exp. Physiol.* 8, 303-30(1915).—An active displacement of Ca salts is a factor in the production of the diastolic failure which follows perfusion of isotonic NaCl through the frog heart. After perfusion of isotonic NaCl (1) the action of Ca salts in shortening the refractory period, (2) the action of the same salts in producing tonus, and (3) their action in supporting the spontaneous contractions are all greatly increased. Two-fold relations exist in the heart between the salts of Na and Ca. They are antagonistic in regard to their mutual adsorption on the surface of certain of the heart colloids (surface effects); they are antagonistic in regard to the changes in the state of aggregation each induces in these same colloids (deep effects). The state of aggregation induced by Ca is one unfavorable to its own activity in its function of tonus production, etc.; the state of aggregation induced by Na favors these latter functions of Ca. The favoring action of Na on these Ca functions outweighs its antagonism. Hence, if the amt. of NaCl in a perfusion soln. be increased, the effective action, in certain directions, of the Ca salts already present in that soln. will

also be increased, but at a distinctly later period, and *vice versa*. Cf. following abstract. V. C. M.

Further experiments on the relation between the action of calcium salts and alkalies on the perfused heart. W. BURRIDGE. Oxford. *Quart. J. Exp. Physiol.* 8, 331-39(1915).—It is shown that the action of the alkali in inducing changes whereby the effective action of a given conc. of Ca in producing tonus is increased, is antagonized by Ca salts, and it is suggested that Ca salts induce a state of aggregation in certain heart colloids which is unfavorable to their own activity in producing tonus. Alkalies first prolong and then shorten the refractory period of the heart, and thus a marked summation of contractions is made possible. Cf. preceding abstract. V. C. M.

The lipid-content of vascular endothelium. J. TAIT AND J. A. HEWITT. Edinburgh and St. Andrews. *Quart. J. Exp. Physiol.* 8, 391-3(1915).—In 2 sets of analyses of the endothelium of the aortae of the ox the Et_2O ext. was found to amount to 8.41 and 9.25%. This did not support the authors' supposition that the slight adhesion of blood to the walls of blood vessels might be due to the existence of a large amt. of lipoids in the endothelium. V. C. M.

The lipid content of peritoneal endothelium. J. TAIT AND W. CAMPBELL. Edinburgh. *Quart. J. Exp. Physiol.* 8, 395-7(1915).—The lipid content of the peritoneal endothelium of 2 sets of bullocks was found to be 15.06 and 14.8%; of 2 sets of sheep, 14.6 and 13.06%. V. C. M.

Displacement by oxygen of carbon monoxide from combination with hemoglobin. MAURICE NICLOUX. *Compt. rend. soc. biol.* 76, 328-31(1914).—The classical view that CO-hemoglobin is a very stable compd., upon which O exerts practically no action, is based upon a misconception, since the interaction of oxyhemoglobin, CO and O should be considered as a balanced reaction, thus: $\text{HbO}_2 + \text{CO} \rightleftharpoons \text{HbCO} + \text{O}_2$ (Hb = hemoglobin). Hemoglobin, when placed in contact with mixts. of CO and O, combines (both *in vivo* and *in vitro*) with the 2 gases in proportions which are detd. by the resp. tensions in the mixt. and regulated by the mass action law. Expts. *in vitro* with pig blood satd. with CO showed that CO was readily displaced by pure O from combination with hemoglobin. The degree of satn. of the blood was expressed as the % of CO-hemoglobin based on the total amt. of hemoglobin, this being the quotient (multiplied by 100) of the amt. of CO present in 100 cc. blood divided by the amt. of CO contained in 100 cc. of the same blood when satd. When pure O was used, the % of CO-hemoglobin decreased from 100 to 7.3 in 12 hrs.; this corresponded to a decrease from 23.15 cc. to 1.7 cc. CO in 100 cc. blood. When air was employed, the % of CO-hemoglobin decreased from 100 to 15.5 in 15 hrs., all other detg. conditions being identical with those prevailing when pure O was used; this corresponded to a decrease from 26.2 cc. to 6.7 cc. CO in 100 cc. blood. Respiration of O is, therefore, the most desirable treatment in cases of CO intoxication, but only those forms of app. which permit introduction of O into the pulmonary alveoli should be used. H. S. P.

Factors affecting the coagulation time of blood. VI. The effect of rapid and progressive hemorrhage upon the factors of coagulation. KATHERINE DRINKER AND C. K. DRINKER. *Am. J. Physiol.* 36, 305-24(1915).—Rapid progressive hemorrhage causes a decrease in coagulation time approx. paralleled by a fall in antithrombin. Prothrombin underwent no regular change, usually increasing slightly, then decreasing slightly. The accuracy of the results for fibrinogen are questioned. A decrease is indicated. Platelet counts did not vary following hemorrhage. J. F. LYMAN.

G. PATHOLOGY.

H. GIDEON WELLS.

Functional modifications produced by cholera toxin on the various systems of the organism. G. CICCONARDI. Univ. of Naples. *Lo sperimentale* 68, 69-112

(1915).—The method of prepg. and purifying the cholera toxin (a nucleoprotein) is given, and the effect of its injection in rabbits and guinea pigs is studied with regard to temp., circulation, respiration, renal function, motor function of the intestine and muscular functions. The effects produced in the animals are similar to the characteristic symptoms of cholera in man, viz.: strong lowering of temp., pathologic variations in the circulation and respiratory app., stoppage of the renal secretion, diarrhea upon exciting peristalsis, and muscular contraction.

H. W. BANKS, 3RD.

Variations in the hemolytic power of the serum of the frog after removal of the liver. V. RONCA. Univ. Modena. *Lo sperimentale* 68, 305-19(1915).—Total removal of the liver caused a marked decrease in the hemolytic power of the serum toward the erythrocytes of a rabbit, and an increase in the metachromatic granular substance of the nucleated cells. The blood as usual coagulated rapidly. When anemia was induced by bleeding, the natural hemolytic power of the serum toward rabbit erythrocytes returned rapidly. The removal of the spleen had no effect upon the production of the natural hemolysins of the frog toward rabbit erythrocytes. Extracts of the liver, spleen, and pancreas did not exhibit this hemolytic power.

H. W. BANKS, 3RD.

The modifications produced in the serum in hemolytic anemia by means of splenectomy during the course of the anemia. P. BASTAI. Institute of pathologic anatomy, Florence. *Lo sperimentale* 68, 357(1915).—Splenectomy has a favorable influence on the course of anemia produced in rabbits by specific hemolytic serum.

H. W. BANKS, 3RD.

Experimental vaccination against cholera vibrio with a vaccine sterilized by ether. H. VINCENT. *Compt. rend.* 160, 378-80(1915).—Ether sterilizes cholera cultures at once and may be used in prepg. cholera vaccines. The ether exts. unnecessary lipins and seems to diminish the ill effects of the vaccine. The bacteria are broken up in the sterilization and, being finely divided, favor rapid formation of antibody. The method seems to be generally applicable to the prep. of vaccines. E. M. FRANKEL.

The action of bacterial filtrates on fixed tissues. R. BRITZOLFF. Univ. Heidelberg. *Beitr. path. Anal.* 60, 337-46(1915).—Pieces of kidney, liver, lung and spleen from freshly killed guinea pigs were fixed by boiling or with CH_3O and put into sterile filtrates of bouillon cultures of different bacteria. The changes produced in the tissues were studied microscopically. They were similar to those seen in post-mortem autolysis. The leucocytes and cells of the myocardium were affected less than the liver and kidney cells, and the connective tissue cells least of all. The substance in the filtrates that produces the changes is of an enzyme nature because it is destroyed upon boiling and only those filtrates that liquefy gelatin act on the tissues. The strongest action was observed with *B. proteus vulgaris* which produces a large amt. of protease in its growth.

JULIAN H. LEWIS.

The influence of an oxidizing substance (sodium iodoxybenzoate) on immune reactions. A. ARKIN. *J. Infect. Dis.* 16, 349-60(1915).—Na iodoxybenzoate, which stimulates physiological oxidations, also stimulates the production of hemolysin and agglutinin in rabbits when injected intravenously shortly after immunization. The action of this substance is probably on the tissues of the body, because it inhibits also the local tuberculin reaction in tuberculous animals.

JULIAN H. LEWIS.

Natural hemolysins in human serum. JOHN A. KOLMER AND ARTHUR J. CASSELMAN. *J. Infect. Dis.* 16, 441-7(1915).—The sheep hemolytic system is the one commonly used in complement fixation work with human serum although the latter contains a large amt. of antihemolysin. With the purpose of finding a more desirable hemolytic system, K. and C. detd. the amt. of natural hemolysins for different animals in human

serum. The amt. of hemolysis indicates the amt. of antihemolysis. A table is given showing the number of sera tested and the amt. of hemolysis of different corpuscles produced. As far as the presence of natural hemolysins is concerned, the following is the order of preferability of hemolytic systems: guinea pig, rabbit, horse, chicken, rat, hog, goat, ox, dog, sheep. JULIAN H. LEWIS.

The ferment activity of blood in infectious diseases. FREDERICK HOWARD FALLS. Univ. Ill. *J. Infect. Dis.* 16, 466-78(1915).—The serum in lobar pneumonia, malaria, acute articular rheumatism, typhoid, meningitis, tuberculosis, tabes dorsalis and paresis gives a positive Abderhalden reaction with placental tissue. Pregnancy and the puerperal state give responses that cannot be differentiated from these reactions. The source of the ferment is probably not to be found in the leucocytes, because the reaction was often strongly positive in cases with a low leucocyte count and frequently weak in conditions in which the leucocyte count was high. JULIAN H. LEWIS.

Serum diagnosis of Rous's chicken sarcoma, based on chemical methods. CASIMIR FUNK. *Biochem. Bull.* 4, 24-9(1915).—Expts. were performed with serum of chickens inoculated with very malignant, Rous chicken sarcoma. Tumor serum was as a rule poorer in N, P and S and richer in amino N than normal. The mol. depression was greater in normal serum. Analysis in the case of Rous sarcoma gives much more reliable results than other diagnostic methods, but is open to the objections that Rous sarcoma differs in many respects from other tumors and that the same chem. differences may be found in other pathological conditions. It does not follow that analogous results can be obtained for human serum. The expts. are in progress. A. P. L.

Reaction of rabbits to intravenous injections of mold spores. A. F. BLAKESLEE AND R. A. GORTNER. Conn. Agr. College and Univ. Minn. *Biochem. Bull.* 4, 45-51 (1915).—The work was undertaken in connection with expts. on the detn. of the chem. differences which may exist between the 2 sexual races in the fungus group of mucors; it was thought that cytolytins might be developed for mold spores which would be sexually specific. Rabbits were injected intravenously with spores of "Mucor V." The injections failed to cause the development of cytolytic substances capable of dissolving the fungus spores but apparently stimulated the formation of antibodies causing agglutination. A. P. LOTHROP.

Comparisons of urinary and serum findings in the diagnosis of tuberculosis. J. BRONFENBRENNER, J. ROCKMAN AND W. J. MITCHELL, JR. West Penn. Hosp., Pittsburgh. *Biochem. Bull.* 4, 80-5(1915).—Urine was examd. by the Ehrlich diazo reaction and the Moritz Weiss test for neutral S, and the findings compared with those of the serum test in 100 cases clinically tuberculous and 100 non-tuberculous cases. The diazo or Weiss test is less const. than the serum reaction and, when positive, is of value only if typhoid is excluded. These tests are not sufficiently frequent in tuberculosis to be of diagnostic value. An increased amt. of neutral S in advanced stages of the disease is quite const. and of prognostic value, especially in connection with corresponding negative findings in the serum. A. P. LOTHROP.

Neutral-sulfur and colloidal-nitrogen tests in the diagnosis of cancer. FREDERIC G. GOODRIDGE AND MAX KAHN. Columbia Univ. and Beth Israel Hosp. *Biochem. Bull.* 4, 118-26(1915).—In cases other than cancer, positive results with the colloidal-N estn. were obtained in myocarditis, diabetes and syphilis; and positive Salomon and Saxl neutral-S reactions in tuberculosis, hemophilia, pernicious anemia and atrophic cirrhosis of the liver. "Positive results with either the colloidal-N or the neutral-S test, alone, are not indicative of carcinoma. When performed *conjointly* on urine of the same case, however, positive results with *both* methods are strongly indicative of malignancy." A. P. LOTHROP.

Active immunization to hay fever. MARK J. GOTTLIEB AND SEYMOUR OPPENHEIMER. New York. *Biochem. Bull.* 4, 127-35(1915).—The authors record the treatment of 11 cases of hay fever with vaccines prepared from ragweed or golden-rod pollen before and during the season for autumnal catarrh. The vaccines, which appeared to be free from protein, were obtained by extg. the pollen grains with salt soln. and pptg. with alc. the "active" material from such exts. There were 5 cures; 4 cases showed marked improvement; 9 cases reacted to ragweed pollen, 2 to that of both ragweed and golden-rod. While immunity may not have been successfully carried over to the succeeding year, recurrences were much milder and required less re-immunization. The investigation will be extended with vaccines from other pollens. A. P. L.

Studies on the theory of diabetes. V. A study of narcotic drugs in phlorhizin diabetes. W. D. SANSUM AND R. T. WOODYATT. Rush Medical College, Chicago. *J. Biol. Chem.* 21, 1-21(1915).—Doses of epinephrine supplementary to injections of phlorhizin remove all the glycogen from the body. This method should be employed in preparing animals for the study of *new sugar* formation following administrations of substances that may cause hyperglucemias in non-diabetic animals. The excretion of extra sugar which has been observed after Et_2O or N_2O narcosis in phlorhizinized dogs has its origin in glycogen as no extra sugar appears after dogs have been treated with phlorhizin plus epinephrine. AcH does not give rise to *new* formations of sugar as claimed by Ringer and Frankel (*C. A.* 8, 954). "The hypothesis that antiketogenesis and diabetic phenomena generally depend upon the occurrence or non-occurrence of glucoside-like unions between aldehydes and alcohol groups is also wholly untenable." The presence or absence of glycogen in diabetic dogs can be shown by subcutaneous injection of 0.25-1 mg. of epinephrine and is a convenient method to use as a check in all expts. on diabetic animals in which the mobilization of glycogen could lead to erroneous conclusions. A. P. LOTHROP.

The several factors of acid excretion in nephritis. LAWRENCE J. HENDERSON AND WALTER W. PALMER. Mass. General Hosp., Boston. *J. Biol. Chem.* 21, 37-55 (1915).—Studies have been made of 44 cases of nephritis involving analyses of the daily excretion for 311 days. Estimations were made of H ion conc., acid excretion, NH_3 and vol. The cases studied divide themselves into 2 groups, group I being characterized by large vol., intense acidity, and diminished total-acid excretion due to a deficit in urinary NH_3 . In group II the urinary vol. is normal, the acidity high and the total acid excretion low or normal, due to fluctuations in NH_3 ; these cases involve degrees of acidosis much milder than in the cases of group I, which consist of sharply defined cases of the same type functionally. A. P. LOTHROP.

The retention of alkali in nephritis. WALTER W. PALMER AND LAWRENCE J. HENDERSON. Mass. General Hosp., Boston. *J. Biol. Chem.* 21, 57-60(1915); cf. preceding abstr.—Acidosis appears to be invariably associated with the type of nephritis in which there is a condition of diminished NH_3 excretion, as in these cases real retention of alkali has been observed when NaHCO_3 was administered. It is frequently associated with other types. It is possible for a condition of acidosis to be accompanied by diminished NH_3 excretion as well as by an increase in the amt. of NH_3 . A. P. LOTHROP.

The effect of acid administration on parathyroid tetany. D. W. WILSON, THORNTON STEARNS AND J. H. JANNEY, JR. Johns Hopkins Univ. *J. Biol. Chem.* 21, 169-77 (1915).—The intravenous injections of 0.286 and 0.143 M HCl in 0.143 M NaCl relieves parathyroid tetany in dogs, the time elapsing before the return of the symptoms varying with the amt. of acid but in some cases extending over several days. NaCl alone has no apparent beneficial effect. The same effect is produced when the HCl is taken by mouth but this method of procedure is usually not efficient, owing to the difficulty with which material is retained in the stomachs of dogs in tetany. These

results suggest "the possibility of a beneficial action due to a variation in the acid-base equilibria in the body" and "that there may be a condition of or tendency towards an alkalosis after parathyroidectomy" which is relieved by the introduction of acid.

A. P. LOTHROP.

On starvation and obesity, with special reference to acidosis. OTTO FOLIN AND W. DENNIS. Harvard Med. School. *J. Biol. Chem.* 21, 183-92(1915).—"Obesity is not a predisposing or contributing factor in the onset or intensity of the acidosis of starvation. By repeated fasts of moderate duration the obese acquire an increased ability to starve without the production of acetone bodies. The obese lose less body protein than others in the course of moderate periods of starvation (4-6 days), and on repeating the fasts the losses of body protein become still smaller. Successive moderate periods of starvation constitute a perfectly safe, harmless, and effective method for reducing the wt. of those suffering from obesity."

A. P. LOTHROP.

Neutralizing power of saliva in its relation to dental caries. J. A. MARSHALL. *Am. J. Physiol.* 36, 260-79(1915).—The neutralizing power of the saliva of 104 persons was detd. by Henderson's method, *i. e.*, the sum of the titrations with 0.02 *N* HCl (*p*-nitrophenol indicator) and with 0.02 *N* NaOH (phenolph. indicator). The reaction of normal resting saliva shows no definite relationship to dental caries. The activated saliva (paraffin stimulus) shows a tendency toward greatly increased neutralizing power in persons immune to caries while in persons with carious teeth this increase is less marked or lacking.

J. F. L.

The cholesterol content of human blood serum. HUGO PRIBRAM. Prague. *Zentr. inn. Med.* 36, 325-8(1915).—The detn. of the cholesterol content of the blood serum throws much light on pathol. conditions. The detn. of total cholesterol is not sufficient. The amts. of cholesterol in the free and in the combined condition deserves greater attention.

JOHN T. MYERS.

The coefficient of Ambard in dementia praecox. A. OBREGIA, C. J. URECHIA AND A. POPEIA. *Compt. rend. soc. biol.* 76, 49-50(1914).—Excretion of N remained practically unchanged in 70% of the cases of *dementia praecox* under observation; retention of N was observed in 30% of these cases. No definite relation between the value of the Ambard coeff. and the condition of exaltation or depression of the patient was established.

H. S. PAINÉ.

Investigation of suprarenal antibodies during the course of suprarenal insufficiency. A. SÉZARY AND P. BOREL. *Compt. rend. soc. biol.* 76, 384-5(1914).—S. and B. attempted to ascertain by means of the method of complement deviation whether suprarenal antibodies analogous to those detected during the existence of lesions of certain other organs are present in the blood of subjects suffering from suprarenal insufficiency. Ox suprarenal ext. was employed as antigen and the expts. were controlled by means of the serum of a rabbit in which severe, exptl. lesions of 1 of the suprarenals had been produced. The results in all cases (7 subjects of which 4 were suffering from well defined Addison's disease) were negative. Positive results were obtained only with syphilitics (who showed no suprarenal lesion). It has already been shown that a suprarenal antigen may be substituted without disadvantage for the usual antigens in the Wassermann reaction. The authors attempted to verify the above results with rabbits the serum of which before the expt. did not produce deviation of complement in the presence of suprarenal antigen or syphilitic liver; only 1 rabbit survived and the serum of this animal did not produce deviation of complement in the presence of suprarenal antigen in 1 month after exptl. lesion of 1 suprarenal.

H. S. PAINÉ.

Action of oxidizing substances on antibodies. MARCEL BÉLIN. Tours. *Compt. rend. soc. biol.* 76, 520-2(1914).—B. has previously demonstrated that toxins are readily

oxidized *in vivo*, thus checking the progress of certain infectious diseases; he has now attempted to ascertain if antibodies in general and antitoxins in particular are likewise affected by energetic oxidizing agents. Guinea pigs were immunized to a colon bacillus by means of a subcutaneous injection of 9.5 cc. culture followed, 8 days afterward, by a 2nd injection (intraperitoneal) of 0.25 cc. culture; at the end of a week all the animals received an intraperitoneal injection of 2 cc. culture per kg., this amt. being sufficient to kill untreated controls in 10-15 hrs. As a result of several subcutaneous injections of NaClO_2 (0.08 g. per kg. in a soln. containing 0.04 g. per cc.) a number of the animals succumbed and the remainder were severely affected; the controls readily withstood the treatment. It is, therefore, concluded that the antibodies were oxidized. B.'s observations regarding the facility of oxidation of toxins *in vivo* emphasize the therapeutic value (especially in acute stages) of this principle, provided a satisfactory oxidizing agent can be found; the latter should be stable, easily handled, quite rich in O and capable of being injected subcutaneously.

H. S. PAINE.

Influence of blood transfusion on hyperglucemia and glucosuria of pancreatic diabetes in the dog. A. J. CARLSON AND H. GINSBURG. *Am. J. Physiol.* 36, 280-93 (1915).—Transfusion of normal blood into dogs in complete pancreatic diabetes caused a reduction in blood sugar and a marked decrease in sugar elimination. The results indicate an increased oxidation of sugar following the transfusion of normal blood.

J. F. LYMAN.

Concentration of sodium chloride in the plasma and its relation to the rate of excretion in normal and diabetic man. F. C. McLEAN. *Proc. Am. Physiol. Soc.; Am. J. Physiol.* 36, 357-8 (1915).—When the conc. of NaCl in plasma falls below 5.62 g. per l. excretion no longer occurs. Of 18 diabetics half had a normal excretion; the others (one exception complicated with severe nephritis) excreted NaCl on a marked-ly diminished threshold.

J. F. LYMAN.

Production of bile pigment outside the liver. A. A. H. VAN DEN BERGH AND J. SNAPPER. *Nederlandsch Tijdschrift Geneeskunde* March 20 and April 3, 1915; *J. Am. Med. Assoc.* 64, 1538, 1624; cf. *C. A.* 9, 1491.—Extravasated blood left undisturbed in tissues, or in some cavity, in time yields a small amt. of bile pigment. If the bilirubin content is greater than that of the blood serum, the indication is that the accumulation is not of recent occurrence. In pernicious anemia blood from the splenic vein was found to contain much more bilirubin than the peripheral blood, and the splenic system was much darker in color, both indicating that the bilirubin in question had been formed in the spleen.

L. W. RIGGS.

Endemic goiter (CLARK) 14.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Influence of hypodermic injections of organic and inorganic preparations of iron in experimental anemia. A. CHISTONI. Univ. Naples. *Lo sperimentale* 68, 53-68 (1915).—The effect of the injections was studied upon rabbits in which anemia had been produced by daily injections of $\text{PhHNNH}_2\cdot\text{HCl}$ (1.25-7 mg. per day). The iron preps. studied were "protoferrina", ammoniacal citrate of iron, and green ammoniacal citrate of iron (2 mg. Fe per day). With organic Fe the hemoglobin is rapidly increased as is the hemoglobin index. At the same time the diminution of erythrocytes is stopped, and eventually the erythrocytes increase in number. Other pathol. indications of anemia disappear or greatly diminish. With the inorg. preps. erythrocytes increase and the hemoglobin increases somewhat; but the pathol. indications of anemia do not disappear or diminish.

H. W. BANKS, 3RD.

Phosphorus in the wounds made by German artillery projectiles. V. HENRI. *Compt. rend.* 160, 82-3(1915).—Shrapnel and shells carry a purple powder containing 97% of P. Wounds caused by them may heal slowly due to the action of such P.

E. M. FRANKEL.

Pneumoconiosis of metal polishers. A. LAFONT, DESMOULINS AND F. HEDM. *Compt. rend.* 160, 328-30(1915).—Clinical observations. Pewter polishers often have lead poisoning.

E. M. FRANKEL.

Comparative pharmacodynamic action of gold in the colloidal form and as soluble salts. H. BUSQUET. *Compt. rend.* 160, 404-6(1915).—Colloidal Au causes marked improvement in the action of the *isolated* heart of a rabbit; similar doses of Au in sol. form diminish coronary flow and cause general depression of activity. In the *intact animal* (dog), 3-5 mg. per kg. of colloidal Au cause diminution of rate, increase in amplitude of the heart and a rise in blood pressure, whereas the sol. Au salts, in similar doses have just the opposite effects and are often toxic.

E. M. FRANKEL.

Effect of alkali water on dairy cows. C. LARSEN AND D. E. BAILEY. S. Dakota Sta., *Bull.* 147, 300-25; *Exp. Sta. Record*, 30, 775.—Cows watered with alkaline H₂O showed nothing abnormal. The principal mineral constituent, Na₂SO₄, was eliminated by the kidneys and caused increased H₂O output over that of the fore-period, despite a diminished intake.

E. M. FRANKEL.

Action of diuretics of the methylxanthine group on normal individuals on different diets. R. WIDMER. Bern. *Z. Biol.* 64, 315-72(1914).—Theophylline in doses of 0.5 g. has a marked diuretic effect when the diet is high (meat) or low (milk) in salts and protein. The absolute increase in the output of H₂O and chlorides, as well as the f. p. depression, is greater on a meat diet though, in relation to the normal urine, there is a greater diuretic effect on the milk diet. Under the influence of the diuretic, the output of salts is relatively smaller than that of water, causing a diminished f. p. depression. On a milk diet, the urinary H₂O output is only about half the intake, while on a meat diet it is about 80% of the intake, due probably to the diuretic action of the extractives in the meat.

E. M. FRANKEL.

Influence of quinine on metabolism. F. SILBERSTEIN. Vienna. *Zentr. Physiol.* 29, 413-21(1915).—Quinine-HCl (0.5-2.0 g.), given *per os* or subcutaneously to dogs, causes very marked increase in blood-sugar content and glucosuria. Doses under 1 g. have little effect on the body temp., but those over 1 g. cause a preliminary rise followed by a fall. Three explanations are offered.

E. M. FRANKEL.

Effects of drugs upon the vessels of the pia mater and retina. ARTHUR D. HIRSCHFELDER. Univ. Minn. *J. Pharmacol.* 6, 597(1915).—Epinephrine, strychnine, cocaine, quinine and ethylhydrocuprein were found to constrict the cerebral and retinal vessels of rabbits and cats, while acetanilide, antipyrine, amyl nitrite, caffeine and alc. dilated them. After digitalis or strophanthin, the caliber of the pial vessels seemed to follow the general blood pressure.

P. J. H.

Effects of digitalis in experimental auricular fibrillation. ARTHUR D. HIRSCHFELDER. Univ. Minn. *J. Pharmacol.* 6, 597-8(1915).—The irregularly beating heart under conditions of continual elec. stimulation was very markedly slowed by digitalis, and also was promptly returned to rapid arrhythmia by paralyzing the vagi with atropine. Section of the vagus was not as effective as atropine.

P. J. H.

A study of the relative importance in the nephritic kidney of a responsive vascular mechanism, as compared with a functionally responsive epithelium in determining the efficiency of various diuretics. WM. DEB. MACNIDER. Univ. N. Carolina. *J. Pharmacol.* 6, 599-601(1915).—With morphine-Et₂O anesthesia, the animals nephritic from 4 mg. U showed a marked diuretic effect from theocine, caffeine, theobromine,

pituitrin, 0.9% urea, 20% glucose, but not with duodenal ext. With Gréhan's anesthetic, the animals nephritic with 6.7 mg. U showed no diuretic effects from any of the substances, although the renal vascular dilatation here often exceeded that of the other animals. Diuretic animals exhibited uninjured renal epithelium, while the nondiuretic animals exhibited cells in various stages of degeneration. The substances here employed are only of diuretic value with uninjured renal epithelium. P. J. H.

Note on the absence of morphine from the liver in a case of chronic laudanum addiction. JACOB ROSENBLOOM. West Penn. Hosp., Pittsburgh. *Biochem. Bull.* 4, 90-3(1915).—The liver of a woman, addicted to the use of large amts. of laudanum for 5 years, was obtained 3 hrs. after death and examd. for morphine according to Dragendorff's process. "The morphine was so changed in the organism, under conditions as yet unknown, that it was impossible to detect morphine; and such a change is marked in cases of habituation to the alkaloid." A. P. LOTHEROP.

Detoxicating effect of the liver of *Cathartes aura* upon solutions of β -imidazolylythylamine. ALLAN C. EUSTIS. Tulane Univ. *Biochem. Bull.* 4, 97-9(1915).—The liver of the common turkey buzzard was chosen because of the fondness of this bird for carrion, on which it thrives. The liver was removed under sterile conditions, ground to a pulp and incubated at 37° for 24 hrs. with 0.1% saline soln. of β -imidazolylythylamine. The filtrate was used for injections into guinea pigs, on a basis of 0.5 mg. of the compd. per 300 g. of wt. No effects were observed with solns. that had been incubated with liver but the usual fatal symptoms appeared with a control soln. The action is apparently due to some enzyme, as heating to boiling inhibits the detoxicating action. A. P. LOTHEROP.

Toxicity of oil of chenopodium. W. SALANT AND E. K. NELSON. *Am. J. Physiol.* 36, 440-63(1915).—Symptoms in cats, dogs, rabbits and guinea pigs after administration of the drug are described. The minimal fatal dose for the cat is about 0.4 cc. per kg. *per os* or 0.2 cc. subcutaneous. The other animals tried have a higher resistance. Simultaneous administration of fixed oils as olive oil, etc., also carbohydrates, have a protective action due to the solubility of the drug in the fixed oil or to the detoxification by glucuronic acid derived from glycogen and glycerides. Ascaridole, the active principle of chenopodium, is 30% more toxic than the oil. A rearrangement product of ascaridole in which the position of the 2 O atoms is changed was less than half as toxic as the oil. Successive small doses showed a cumulative effect. J. F. L.

The movements of the isolated small intestine and the action of various drugs and extracts upon them. A. W. YOUNG. Edinburgh. *Quart. J. Exper. Physiol.* 8, 347-75(1915).—For the expts. a modification of the method of Magnus was employed on the isolated small intestine of the cat. NaHCO_3 in conc. of 0.01-0.04% increases the tone of the intestine without altering the pendulum movements; with higher conc. the movements are inhibited. HCl inhibits both the tone and the movements of the intestine; inhibition is seen with 0.0005%. CO_2 has an inhibitory action on both the tone and movements of the intestine. Hyoscyamine has a stimulating action and can initiate the movements when they are absent. The action of hyoscyne is similar to that of hyoscyamine but weaker, stimulation being produced by 0.02% conc. of the former and by 0.001% conc. of the latter. Both drugs inhibit the stimulation produced by pilocarpine. Cocaine has a stimulating action in strengths from 0.001 to 0.01%; with higher conc. no stimulation is seen, but a marked regularizing effect then appears; with 0.2% paralysis of the intestine occurs. Choline produces a marked rise of tone which occurs with conc. of 0.002%; with higher conc. the pendulum movements are obliterated; atropine inhibits the action; choline and epinephrine are mutually antagonistic. Neurine in its action resembles choline, but is more powerful, acting in 0.001% conc. Aq. ext. of the pituitary in high conc. raises the tone and causes the

development of large tonus oscillations. Hemisine causes inhibition of the movements and lowering of the tone of the intestine even in conc. of 0.00001%. Exts. of spleen, thyroid, thymus, pancreas, liver, kidney and brain give no definite results. Stomach contents inhibit the movements by their acidity alone. The contents of the small intestine have often a marked stimulating effect apart from, but to a considerable degree influenced by, their reaction. Pancreatic secretion increases the tone. Indole inhibits the movements and lowers the tone. Bile has a similar action. V. C. M.

Paradoxical effect of atropine. M. PETZETAKIS. *Compt. rend. soc. biol.* 76, 522-3 (1914).—After injection of 0.002 mg. atropine the pulse of a human subject decreased gradually to a minimum of 54 (reached after 40 sec.), the normal pulse of 78 being regained after 3 hrs. This result is in accord with similar observations of various investigators (particularly Morat) and may be interpreted as being due to increased excitability of the cardio-inhibitory centers or a decrease in the excitability of the cardio-accelerative centers. H. S. PAINE.

Physiological action of proteoses. R. B. GIBSON. *Philippine J. Sci.* 9B, 499-502(1914).—Witte peptone, after repeated treatment with 80-85% hot alc., yielded 20% of semicrystalline alc.-sol. proteoses. These, after intravenous injection into dogs, produced the typical fall in blood pressure and inhibition of blood-clotting that have also been repeatedly ascribed to other proteose preps. Since his expts. showed that the amt. of alc.-sol. proteoses necessary to produce the above effects (0.4 g. per kg. body-wt.) does not depend upon the degree of purification of the material, G. concludes that the action must be ascribed to the proteoses themselves, and not to an alc.-sol. impurity. W. A. PERLZWEIG.

Lymphagogic action of the Philippine mango, *Mangifera indica* Linnaeus. R. B. GIBSON AND I. CONCEPCION. *Philippine J. Sci.* 9B, 503-8(1914).—The rash-producing effects of ingestion of the fruit of the mango among the Philippine natives led to this investigation. G. and C. found the exts. of the dried pulp less effective than the strained and centrifuged raw juice. This was injected into anesthetized dogs. There was increased flow of lymph (almost 3 times normal), which was richer in solids than that before injection. Invariable fall in blood pressure and frequent inhibition of blood-clotting were produced. These facts place the mango juice in Heidenhain's lymphagogs of the first class (see *Arch. ges. Physiol.* 49, 209(1891)). W. A. P.

Fuller's earth; its adsorptive power, and its antidotal value for alkaloids. BERNARD FANTUS. Univ. Ill., Chicago. *J. Am. Med. Assoc.* 64, 1838-45(1915); cf. C. A. 7, 2663; 8, 3868; 9, 225.—"Alkaloidal fuller's earth compds. do not act on the stomach; but are gradually dissociated in the intestines, producing a delayed and milder general action. It has an antidotal value in morphine, cocaine, nicotine, and ipecac poisoning. It has less value in strychnine and aconitine poisoning, though even in these conditions it is capable of saving life, when combined with NaH_2PO_4 . The power of adsorbing alkaloids is strongly developed in some fuller's earths and very feeble in others. Lloyd's reagent possesses this power to the highest degree. Fuller's earth is not synonymous with kaolin, as the U. S. and National Dispensatories would lead one to infer." L. W. RIGGS.

Action of animal charcoal on peptic digestion. M. DIVELLA. *Polidinicco* 22, No. 4(1915); *J. Am. Med. Assoc.* 64, 1883.—D. exptd. with bone charcoal mixed with the mucosa taken fresh from the stomach of a pig or dog, and ground in a mortar. Digestion was materially accelerated by the charcoal admixt. in a proportion of 22%. Larger or smaller proportions were far less effectual. In the presence of poisons (strychnine, As, etc.) digestion proceeded much more effectually with the charcoal than without. L. W. RIGGS.

Diuresis induced by intravenous injection of hypertonic sugar solutions. G. TURRETTINI. *Revue méd. de la Suisse Romande* 35, No. 4(1915); *J. Am. Med. Assoc.* 64, 1947.—T. gives details of several cases of acute nephritis resulting from HgCl_2 poisoning or otherwise, in which the kidneys had ceased to act. From 300 to 500 cc. of a 25-40% soln. of glucose were injected resulting in the establishment of diuresis.

L. W. RIGGS.

Sodium fluoride poisoning. J. N. STANTON AND MAX KAHN. Pittsburgh. *J. Am. Med. Assoc.* 64, 1985(1915).—This appears to be the first case of poisoning by NaF on record. The toxic effects of the F ion are similar to those of the oxalate ion. Intravenous injections of from 0.05 to 0.1 g. NaF per kg. of dog are fatal. A 0.03% soln. of NaF will destroy epithelium. The history of a case is given. L. W. R.

Allylmorphine sulfate (enormorphone) and its pharmacodynamic effects. A. MAJOR AND WIKI. *Rev. méd. de la Suisse Romande* 1915, No. 1; *Pharm. J.* 94, 32. (1915); *Schweis. Apoth. Ztg.* 53, 119-21(1915).—Its chem. comp. is: $(\text{C}_{17}\text{H}_{17}\text{NO}(\text{OH})-(\text{OC}_2\text{H}_5)_2)_2\text{H}_2\text{SO}_4$, forms white needles, m. 173-175°, sol. in H_2O , sparingly sol. in CHCl_3 . Its pharmacological action is individual and different from that of morphine. It depresses the central nervous system, producing moderate somnolence. The local analgesic effect resembles that of morphine. It does not retard respiratory rhythm, and in medium or strong doses rather accelerates it. The compd. is a convulsant for animals in doses similar to codeine. It strongly depresses the blood pressure in the dog, due to an active vasodilatation of peripheral origin. The toxic doses for hypodermic injections are for frog, av. wt., 0.025-0.03 g.; guinea pig, per kg., 0.10-0.11 g.; rabbit per kg., 0.09-0.10 g. It is deduced that therapeutic doses of allylmorphine can have no ill effects on the human heart. It could be used as a sedative hypotensor, and moderate doses are very probably well tolerated by man. S. WALDBOTT.

Metabolic influences of bathing in the great salt lake. HELEN I. MATTILL AND H. A. MATTILL. *Am. J. Physiol.* 36, 488-500(1915).—Two subjects on a uniform diet eliminated in the urine during the bathing periods (lake water contained 19.2% solids, 93% of which were chlorides as NaCl) total N 7 and 5% resp., in excess of that of the fore period. Creatinine elimination was slightly increased while chlorides showed a rise of 21% and 27%. The latter suggests an absorption of chloride through the skin.

J. F. LYMAN.

Biological researches on combinations of amino acids with formaldehyde. A. AZZI. University of Naples. *Lo sperimentale* 69, 1-27(1915).—Expts. on dogs and chickens show that compounds of NH_2 acids with HCHO introduced into the gastrointestinal canal are easily absorbed. This is most evident in the expts. on dogs, in which the increase of total N in the urine on the day of the administration of the substance (and also on the next day) corresponds very nearly to the N introduced. There is an increase in uric acid N in chickens, and in urea-ammonia N in the dogs, and this increase, at least in the dogs, is parallel to that of the total N. In the substances used, the special properties which the NH_2 group acquires are not such as to impede physiological deamidation; and the HCHO compounds, although for many reasons different from the pure amino acids, can still serve in metabolism of the higher animals.

R. A. GORTNER.

Further experiments on the relative effect of weak and strong bases on the rate of oxidations in the egg of the sea urchin. JACQUES LOEB AND HARDOLPH WASTENEYS.

Rockefeller Inst. *J. Biol. Chem.* 21, 153-8(1915).—Fertilized eggs of *Arbacia* were suspended in neutral 0.5 *M* NaCl + KCl + CaCl₂ soln. and to portions varying amts. of NaOH and NH₄OH were added, and the rate of oxidations for 1 hr. detd. The effects of both are closely parallel, that of NH₄OH being considerably greater than would be expected if both NaOH and NH₄OH acted only through their OH-ion conc. This might be explained on the assumption that the weak base diffuses into the egg and accelerates the rate of oxidation, both at the surface and beneath the surface layer, while the action of the strong base is confined to the surface, accounting thus for the relatively excessive efficiency of NH₄OH. If this conclusion is correct, not only the surface but also the layers adjacent to the surface must be considered the seats of cell oxidations, the greater rate of oxidation at the surface being due to the fact that most of the available O is used up at the surface so that comparatively little can diffuse into the cell. A. P. L.

Perca globulin. OTTO FOLIN AND W. DENIS. Harvard Med. School. *J. Biol. Chem.* 21, 193-4(1915).—Perca globulin, discovered by Möerner (*Z. physiol. Chem.* 40, 429(1903)) in the eggs of the ordinary European perch (*Perca fluviatilis* L.), has been found in the roe of the American perch, *Perca flavescens* and *P. sorbuscedion*.

A. P. LOTHROP.

Simplest constituents required for growth and completion of the life cycle in an insect (drosophila). JACQUES LOEB. New York. *Science* 41, 169-70(1915).—Drosophila eggs laid upon sterile culture medium, consisting of sucrose or glucose soln. to which certain salts and a little filter paper were added, developed into larvae. Their growth stopped after a few days and, after a time, they died in the larvae stage. If a small quantity of one or two NH₂-acids, *e. g.*, alanine or glutamic acid, or certain NH₄ salts, *e. g.*, paratartrate, or succinate, or a combination of one NH₄ salt and one NH₂-acid was added, the larvae grew to full size, metamorphosed into pupae and normal flies. Although the filter paper contd. only 0.008% N or 1/2000 to 1/1000 of the N in the medium, the substitution of glass beads for it, to prevent the drowning of the flies, led to decidedly poorer results. The author proposes to investigate this point. W. A. PERLZWEIG.

The adaptability of amphibia to the external liquid media, by means of the regulation of the osmotic pressure of their internal liquids. III. Chemical and physico-chemical properties of the internal liquids of animals kept in distilled water and in hypertonic Ringer solutions. BRUNO BRUNACCI. *Atti accad. Lincei* 23, II, 645-51 (1914); cf. *C. A.* 8, 3475.—In continuing the expts. described previously, B. tested out the effect of keeping frogs in distd. H₂O and Ringer solns. on the f. p., cond., dry residue, ash and organic matter in the blood and lymph. In series (a) *Rana esculenta* were kept in distd. H₂O; in series (b) they were kept a short time in max. hypertonic Ringer soln. (1.0% NaCl and all other salts in proportion); in series (c) they were kept a short time in ultramaximum hypertonic Ringer soln. (0.1% NaCl, etc.); in series (d) they were kept a long time in (1) slightly hypertonic and (2) still more hypertonic Ringer solns. The analytical data are given in 5 tables. In general it was found that the frog adapts itself to the increased conc. of the external liquid media by raising the conc. of its internal liquids. This increase at first takes place at the expense of the surrounding electrolytes but later it is more at the expense of the osmotically active organic material that is obtained from the organism. A comparison of the elec. cond. of the lymph and of the blood shows that the osmotic pressure of both tends to remain at a level higher than that of the external media. Another fact that was clearly observed is the succession with which lymph and urine are formed. At first lymph is formed and then urine. The former increases rapidly in the 1st hr. and remains at a high level for the 1st 8-10 days; then it diminishes gradually and finally disappears altogether. The urine is formed later from the lymph but its elimination into the medium is continuous.

E. J. WITZEMANN.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

The training of food chemists. A. JUCKENACK. *Z. Nahr.-Genussm.* 28, 472-80 (1914).—Changes in the practice in vogue in Germany are proposed. A. F. SEEKER.

Chicory and its substitutes. E. COLLIN. *Ann. fals.* 8, 63-79(1915).—Since the beginning of the war the price of chicory has trebled and is still going up. The principal supply of chicory used to come from Flanders and those parts of France now controlled by Germany. The macroscopic characteristics of chicory and its substitutes are described, and numerous cuts showing the microscopic appearance and histological characteristics given. Powdered chicory, beets, carrots, artichokes, figs, barley, apples, pears, leguminous seeds, *Cassia occidentalis*, acorns, grape seeds, browned bread, peat, coffee marc and date seeds, are treated in detail. Peanut, cacao, bean, almond and other shells, and even sawdust are sometimes found in chicory mixts. H. S. BAILY.

Heather tea, a substitute for black tea. SCHNEIDER. *Pharm. Zentralhalle* 1914, Nos. 49-51; *Schweis. Apoth. Ztg.* 53, 173-4 (1915).—The infusion of the flowering branches of *Calluna vulgaris* is pale yellow, has a faint odor and a feebly astringent taste. It is recommended as a substitute for tea which is becoming scarce in Germany. As the flowers are visited by bees, the herb may be gathered after flowering. The infusion is said to have faint diaphoretic properties. S. WALDBOTT.

The structure of pepper. Some new features. T. E. WALLIS. *Analyst* 40, 190-197 (1915).—Illustrated description of previously unnoted microscopical features. P. B. DUNBAR.

Chemical analysis of spices. CH. ARRAGON. Lausanne. *Schweis. Apoth. Ztg.* 53, 220-5(1915).—The methods of the Swiss Food Code for exam. of spices require modification. For detn. of H_2O distil 10 g. of substance with 60 cc. of oil of turpentine (b. 140-160°) in a special app. and centrifuge the receiving vessel. The H_2O collects at the bottom of a narrow 2 cc. tube graduated into 0.05 cc. Results on materials free from volatile matter agree well with those obtained by direct drying. For detn. of fatty matter and essential oils, dry 10 g. of material over H_2SO_4 for 6 hrs., ext. with dry Et_2O for 8 hrs., distil off the Et_2O at the rate of 1 drop per sec., remove traces of Et_2O by air current, cool and weigh. This detn. fat + essential oil. Distil off the latter by steam to a vol. of about 250 cc. Take up residue with 40 cc. Et_2O , evap. Et_2O in tared flask, dry for 1 hr. and weigh the fat. By difference the essential oil is detd. For detn. of starch, the method of Sachse is followed, modified by 1½ hrs. instead of 3 hrs. boiling, and use of HCl , $d = 1.125$. Cellulose is detd. by König's method. Of 33 authentic specimens of various spices, results of detns. of H_2O , ash, fat, essential oils, protein, cellulose and reducing substances (from starch test) are given. Numbers from the same spice are rather constant. Examn. of 50 com. samples gave results close to those for genuine samples. S. WALDBOTT.

The adulteration of marjoram. R. SEEGER. Innsbruck. *Z. Nahr.-Genussm.* 29, 156-58 (1915).—Out of many samples of marjoram purchased in different cities in Austria, 83% were found adulterated, the poisonous *Coriaria myrtifolia* L., *Cistus* and *Alibaea* being the main adulterants. These adulterants ran as high as 80% in some of the samples. The method of detg. the *Coriaria* is as follows: Boil a 2 cc. sample 1 min. in a test tube with alc. to expel the air from the interior of the leaf particles, heat in 10% KOH for 2 min. to clarify and differentiate the particles, as the different species of leaves will turn different colors, the marjoram remaining light brown or yellow, while the *Cistus* becomes black, and the *Coriaria* brown. Wash out the KOH with H_2O , and then sep. the leaf particles mechanically under a lens. An approximate

quant. sepn. can be made by suspending a little of the sample in water. *Coriaria* being heavier, sinks to the bottom, while the marjoram floats on the water. By sepg., drying and weighing, the % comp. may be detd. Most of the adulterated samples were imported from Southern France.

HELEN N. ELLIOTT.

The seeds of the *Chenopodium album* L. T. F. HANAUSEK. *Z. Nahr.-Genussm.* 29, 17-26(1915).—A study of the microscopic detection of the seeds of this weed in coarse meals occasioned the investigation of the plant. This, or similar plants, has been used since early times as an emergency food, especially as "famine bread" in Russia in 1891-2. A detailed morphological and anatomical description of the seed is given. An appendix of the article deals with the so-called "red-grass" of Russia, a name which seems to be applied to different plants in different districts.

L. D. ELLIOTT.

Acidity and ash of vanilla extract. A. L. WINTON, A. R. ALBRIGT AND E. H. BERRY. *J. Ind. Eng. Chem.* 7, 516-9(1915).—In 77 samples examd. total acidity ranged from 30 to 52 cc. 0.1 *N* alkali per 100 cc., acidity other than vanillin 14-42 cc., total ash 0.220-0.432 g. per 100 cc., sol. ash 0.179-0.357 g. per 100 cc., alkalinity of total ash 30-54 cc. 0.1 *N* acid per 100 cc., alkalinity of sol. ash 22-40 cc. 0.1 *N* acid per 100 cc. The same values were found with and without sugar or glycerol in the menstruum. Ash was increased and acidity decreased by diminishing the strength of alc. in the menstruum.

ISADOR MILLER.

Modification of Wichmann's method for the detection of small amounts of coumarin, particularly in factitious vanilla extracts. J. R. DEAN. *J. Ind. Eng. Chem.* 7, 519 (1915).—The modification is independent of the presence of salicylic acid and saccharin. Render a de-alcoholized portion of the ext. alk. with 5 cc. NH_4OH and ext. with 15 cc. Et_2O . Transfer Et_2O to nickel or porcelain crucible and evap. Add 5 drops 50% KOH , dry and fuse at lowest possible temp. Avoid blackening. Dissolve mass in a few cc. H_2O , acidify with dil. H_2SO_4 and transfer to a test tube. Add 5 cc. CHCl_3 , shake vigorously, allow to settle and remove CHCl_3 with pipet. Filter CHCl_3 , add 1-2 cc. H_2O containing a drop FeCl_3 and shake. Coumarin is indicated by the formation of the purple color of ferric salicylate.

ISADOR MILLER.

The interpretation of the results of the analysis of fatty substances. Issued by the French Bureau for the Suppression of Adulteration, for the interpretation of analyses made by the official French methods. *Ann. fals.* 8, 81-9(1915).—Cow butter: av. consts. for pure butter; Crismer no. (EtOH = 0.7967 sp. gr.), 54; R. no. (by glycerol method), 28; Polenske no., 2.25; sapon no., 225; total sol. acids, 24. The figs. for oleomargarine, coconut butter, lard, tallow and vegetable oils used in margarine are given, together with a formula for calcg. % of some of these when found in butter; olive oil, walnut oil, lard and cacao butter are similarly treated.

H. S. BAILEY.

The examination of animal fats for phytosterol. M. FRITZSCHE. *Z. Nahr.-Genussm.* 29, 150-1(1915); cf. *C. A.* 8, 1315.—The official method of examg. animal fats for vegetable fats in Germany has consisted in detg. phytosterol by the Marcusson-Schilling-digitonin reaction (cf. *C. A.* 8, 1022). Klostermann has shown this method to be faulty (*C. A.* 8, 3246), by proving that all the phytosterol in fats is not in the free form, but partly present as an ester, and therefore not all sapond. in the above method. F. has made comparative detns. by the original method and by the modification proposed by Klostermann and finds the latter to be more sensitive.

HELEN N. ELLIOTT.

Cholesterol content of egg fat. P. BERG AND J. ANGERHAUSEN. *Hamburg. Z. Nahr.-Genussm.* 29, 9-10(1915).—Tests for cholesterol by the digitalin method of sepn. were made on 6 samples of egg yolk; (1) a sample of yolk from an oleomargarine factory; (2) and (3) 2 samples of Chinese hen yolk; (4) a domestic hen yolk; (5) and (6) 2 Chinese duck yolks. The yolk after drying with sand was extd. with ether, the

ext. evapd., filtered and dried. Five g. of the resulting fat were sapond. with alc. potash and the unsapon. matter taken up with ether, according to the "meat inspection methods," shaking out 6 times with ether instead of four. The total unsapon. matter obtained from the egg fats was: (1) 3.37%, (2) 4.84%, (3) 4.96%, (4) 5.08%, (5) 4.22%, (6) 4.22%. The value of $[\alpha]$ in (1) was -32° , corresponding closely to that of pure cholesterol. The alc. soln. of the unsapon. constituents was pptd. with digitalin (cf. C. A. 9, 249). The cholesterol contents corresponding to the digitalin ppt. obtained for the 6 samples were: (1) 3.0%, (2) 4.34%, (3) 4.44%, (4) 4.44%, (5) 3.84%, (6) 3.94%. Should further expts. show no more variation in the cholesterol content of egg fats, the detn. of cholesterol in egg noodles, egg cognacs, etc. should be of value. The large wt. of the digitonide ppt. makes the quant. estn. of small amts. of the latter a simple matter.

L. D. ELLIOTT.

The pasteurization of milk. BORDAS. *Ann. fals.* 8, 89-93(1915).—A discussion of the relative merits of various pasteurization methods as applied to milk.

H. S. BAILEY.

The titration of milk with alcohol of various concentrations. W. D. KOOPER. *Molkerei Ztg. Hildesheim* 28, 715(1914); *Biedermanns Zentr.* 44, 129(1915).—K. investigated the method recommended by Löhnis (cf. C. A. 9, 492) with a view to making the test more accurate. From the results of his expts. he is led to doubt whether this can be looked upon as a quick method for detg. the bacterial content of milk, even if it could be carried out practically. "If such large variations occur in mixed milks, to what extent can this be the case in single milks which are subject to much larger variations in their chem. and biol. nature?"

C. F. MILLER.

The bacteriology of cheese of the Emmenthaler type. E. E. ELDRIDGE and L. A. ROGERS. U. S. Dept. Agr., Bur. An. Ind. *Centr. Bakt. Parasitenk., Abt. II* 40, 5-21 (1914).—The problems involved in the ripening of Cheddar and Emmenthaler cheeses are discussed and a review of the literature is given. A whey agar gave the most satisfactory results for a systematic study of the bacteria of Emmenthaler cheese. Cultures of *B. bulgaricus* form good sized colonies on this medium in 4 or 5 days at 30° . Quant. and qual. bacteriological analyses of 3 domestic Emmenthaler cheeses were made through a nearly complete ripening period. The organisms isolated were divided into 3 groups: A coccus, a very short slender rod and a long rod. Most of the cultures grew scantily or not at all in ordinary broth. The fermentation tests with a special broth failed to differentiate the cultures into distinct groups. None of the organisms fermented starch. As some of the cultures formed gas, a special medium was prepared to favor this characteristic. The CO_2 produced was absorbed by a standard soln. of $\text{Ba}(\text{OH})_2$ in a special fermentation tube designed for this work. Thirty % of all the cultures produced less than 1 cc. of CO_2 ; 4.7% produced over 5 cc. The bacterial counts showed that young cheese contained short rods almost exclusively and that the max. number of these organisms occurred in from 6 to 10 weeks. The cocci appeared at intervals during the ripening process. The short and long rods were about equal in number after 6 or 8 weeks while the max. of the latter group occurred in from 9 to 23 weeks. Towards the end of the ripening period the long rods were usually the only ones present. The propionic bacteria of Freudenreich and Jensen were found only once in small numbers in a special cheese. Preliminary inoculation expts. have indicated that normal cheese of excellent quality may be made by adding pure cultures to the milk.

F. M. SCALES.

Chemical viewpoints in the preparation of Grana cheese. G. FASCETTI. *Staz. sper. agrar. ital.* 47, 541-68 (1914); through *Chem. Zentr.* 1915, I, 387.—The acid content of the milk is of great influence on the cheese formation, during which process the ash content of the serum increases. This increase takes place at the expense of

the CaO and P_2O_5 content. In natural souring an equil. between the ash constituents of the serum and the casein mass is gradually approached and a special fermentative equil. among the bacteria, different for various cheeses, is reached. L. J. G.

A method for the estimation of chlorides in cheese. ELFREIDA C. V. CORNISH AND JOHN GOLDING. *Analyst* 40, 197-203 (1915).—The method is as follows: Weigh 1 g. of cheese on a Cl-free filter paper and place in a Kjeldahl flask with 20-30 cc. concd. N-free H_2SO_4 and a few small pieces of pumice. Connect the flask with an absorption bottle containing a known amt. of 0.1 N AgNO_3 and 50% of concd. HNO_3 . Connect the bottle in turn with a control wash bottle and an aspirator. To avoid the use of a rubber or cork stopper the Kjeldahl flask is connected with the absorption bottle by means of a bent soda-lime tube the tubular end of which is large enough to just fill the neck of the flask. After the addition of the H_2SO_4 and a little distd. water connect the app. and begin the aspiration. Mix the contents of the flask well by rotating; then heat gently at first and finally to boiling. In order to prevent condensation of HCl in the neck of the flask heat the neck with a movable Bunsen burner or by means of a specially fitted steam bath. When the reaction is completed (detd. by inserting another absorption bottle with fresh AgNO_3 soln.) filter off the AgCl , wash the ppt. free from AgNO_3 and add the washings to the filtrate. Det. the residual AgNO_3 by the Volhard method. The soln. remaining in the Kjeldahl flask may be utilized for the detn. of N. P. B. DUNBAR.

The determination of the meat extract content of bouillon cubes. T. SUDENDORF AND O. LAHRMANN. Hamburg. *Z. Nahr.-Genussm.* 29, 1-8 (1915).—This detn. being based upon the creatinine content of the cubes renders an exact detn. of this constituent essential. Some materials, not containing creatinine, that are at times employed in the prep. of bouillon cubes react with alkaline picrates to produce colors which vitiate detns. conducted by the Folin method. Such materials are yeast ext., caramel, and tomato juice. All of these, particularly the last, when used in amts. that might be employed in bouillon cubes were found to produce a coloration equiv. to notable amts. of creatinine. Similar results were obtained with acetone, Et acetoacetate, H_2S , hydroquinone and semi-carbazide, which might be used to simulate the reaction for the purpose of deceiving analysts, though such a contingency is regarded as unlikely, due consideration being given to the fact that the first three would be eliminated in the process of inversion. Expts. showed that bone charcoal is not suitable as an agent for removing any of these substances since it also removes some of the creatinine. Complete success was obtained by preliminary treatment with KMnO_4 according to the Lendrich and Nottbohm method for purifying caffeine exts. (cf. *C. A.* 3, 1429), exptl. evidence given showing that in the presence of NaCl the interfering substances are completely eliminated without affecting the creatinine. The complete method follows: Prepare an aq. soln. of the bouillon cubes of known strength (about 10%) and filter to remove fat. Introduce an aliquot portion of the filtrate (10-20 cc.) into a porcelain (75 cc.) capsule, add 10 cc. of N HCl and evap. to dryness on a steam bath, allowing 2 hrs. for the evapn. Dissolve the residue in water, exactly neutralize to litmus with 0.5 N NaOH , rinse into an Erlenmeyer flask and dil. to about 75 cc. with water. Add KMnO_4 soln. (1% KMnO_4 containing 2.5% NaCl) drop by drop with const. shaking until the reddish color of KMnO_4 persists for several min. If the mixt. becomes thick, dil. with a little water. Then add H_2O_2 soln. (3% H_2O_2 containing 1 cc. glacial acetic acid per 100 cc.) drop by drop until excess of KMnO_4 is destroyed, and heat on a steam bath for 5-10 min. or until the Mn oxides flocculate. Filter by means of suction and wash the ppt. until the Cl reaction disappears. Evap. the almost colorless filtrate to small vol., rinse into a 500 cc. graduated flask, make up to about 20 cc., cool, and treat with 10 cc. of 10% NaOH and 20 cc. of satd. picric acid

soln. After standing 5 min. make up to the 500 cc. mark with water and compare the color in a Duboscq colorimeter against 0.5 N $K_2Cr_2O_7$ of which a column of 8 mm. corresponds to 10 mg. of creatinine.

A. F. SEEKER.

Investigation and examination of sausage. D. SCHENK AND H. BURMEISTER. Hyg.-chem. Investigation Sta. of the 21st Army Corps. *Z. Nahr.-Genussm.* 29, 146-50 (1915).—The convenience of sausages in transportation is bringing this form of food into general use in the army. E. Feder found that in meats the ratio of H_2O to organic non-fats is about 3-1 and should not be over 4-1 (cf. *C. A.* 7, 3170; 8, 3601). S. and B. applied this method to the analysis of a large number of samples of fresh sausages which were to be examd. for adulteration. In the case of smoked sausages the salt content of the sample affords one of the best means of detg. the value of the sausage, since the presence of an excessive amt. of NaCl is common in this product.

LOUIS D. ELLIOTT.

Sardines in olive oil. G. BLANC. *Ann. fals.* 8, 79-80(1915).—The French law requires that "Sardines a l'huile d'olive pure, vierge, extra," etc., be both cooked and packed in pure olive oil. As a special provision "Sardines a l'huile d'olive" may be cooked in oils other than olive, but must be packed in pure olive oil. The oil present in the fish effects the const. of the olive oil as drained from the canned sardines. B. concludes from his expts. that all olive oils from French-canned sardines which have an I no. above 90 and an oleorefractometer reading greater than plus (eleven) are adulterated.

H. S. BAILEY.

Effect of the mineral content of water on canned foods. H. L. HUENINK AND E. BARTOW. *J. Ind. Eng. Chem.* 7, 495-6(1915).—H. and B. describe results of expts. on canning beans, using distd. H_2O , and H_2O containing definite amts. of $CaCl_2$, $MgCl_2$, Na_2CO_3 as well as mixts. of $CaCl_2$, $CaSO_4$, $Ca(HCO_3)_2$, $MgCl_2$, $MgSO_4$, $Mg(HCO_3)_2$, Na_2CO_3 and $NaHCO_3$.

ISADOR MILLER.

Investigation of commercial fruit jellies. LEON A. CONGDON. *North Dakota Special Bull.* 3, No. 8, 112-24 (1914).—Detailed analyses of nineteen jellies are presented in tables.

R. C. ROARK.

Notes on the hydrocyanic acid content of sorghum. J. J. WILLAMAN AND R. M. WHEAT. *J. Agr. Res.* 4, 179-85(1915).—When sorghum is grown on poor, infertile soil, added N may slightly increase the amt. of HCN in the plant. With a fertile soil and abundant N this effect may not be produced. During the first 3 or 4 weeks of the plant's life the HCN is concd. in the stalks. Then it rapidly decreases and disappears from there but apparently persists in the leaves in decreasing % until maturity. Climate and variety may be more important factors than soil N in detg. the amt. of the acid in the plant. Complete hydrolysis of the glucoside (dhurrin) is obtained by digesting the macerated tissue for 2 hrs. at 40-45°.

M. X. S.

Hydrocyanic acid from haricot beans. HERBERT BLAIR. *Pharm. J.* 94, 586 (1915).—Some haricot beans (*Phaseolus lunatus*) were steeped overnight in a covered pan. On opening the pan, a strong odor of HCN was noticed. The beans were then boiled and eaten without ill effect. Their comp. was as follows: H_2O , 12.8; ash, 3.75; fat, 1.86; fiber, 4.58; albumin, 19.05; carbohydrates (by difference), 57.96%. To det. the amt. of HCN formed, 1 g. of ground beans was macerated in H_2O at 45°, and the HCN conducted into dil. KOH soln. by a current of pure H passing through the liquid at the rate of 10 l. per hr. After 27, 49, 87, 117, 198, 358 min., the following amts. of HCN in fractions of a mg. were absorbed: 0.025, 0.050, 0.080, 0.100, 0.120, 0.160 mg. resp.

S. WALDBOTT.

What purpose is achieved by treating pearl barley with sulfur dioxide and talc? W. FLÜCKER AND R. FLEBBE. *Z. Nahr.-Genussm.* 28, 549-70(1914).—A compre-

hensive review of the literature is given upon the occurrence and favorable conditions for the growth of microorganisms upon food grains of various kinds. The contention of millers that the use of SO_2 and talc is required to preserve pearl barley properly was subjected to exptl. investigation, the conclusion being that when the grain is properly dried to a moisture content of 12% or less and suitably cleaned and decorticated the product will keep as well without sulfuring. Numerous bacteriological tests showed that in general crude barley gave a total bacterial count exceeding 1,000,000 per g.; after washing this was reduced to 100,000, and after decortivating to less than 50,000. Comparative counts in decorticated barley of heat-resisting bacteria showed between 60 and 1280 for the untreated product, and between 20 and 300 for sulfured barley, the corresponding figures for mold spores being 20 to 5920 and 10 to 975, resp., and for total bacteria 4,600 to 65,350 and 100 to 2680. The authors consider that these differences are practically insignificant insofar as the actual keeping qualities of the grain are concerned. The efficiency of talc as a preservative was tested by storing samples coated with 0.2 to 1.38% as well as untreated barley in a moist atm. No difference in keeping quality was observed. The authors conclude that SO_2 and talc are employed primarily to bleach the grain and to secure a uniformity of appearance that makes inferior Russian barley resemble the more expensive German grain. Incidentally it permits a higher moisture content without danger of spoiling. A. F. SEEKER.

Microscopic detection of potato starch in bread. G. SCHÜTZ AND L. WEIN. Kgl. Hygien. Inst., Beuthen. *Chem. Ztg.* 39, 143(1915).—A few crumbs of bread are softened with a little H_2O on a watch-glass, mixed, a small portion placed between 2 cover-glasses and carefully pressed and rubbed thin and uniform and the glasses sepd. and completely air-dried and fixed in the usual way by passing through a flame 3 times. A few drops of strong soln. of neutral red are added and left 1–1.5 min. in the cold, then carefully washed off, and the substance in the H_2O examd. with low power. Rye and wheat starch are colorless, potato starch a transient rose-red. Similar treatment with a strong soln. of methylene blue dild. with 9 parts H_2O , allowing 1 min. to color, gives a deep blue to potato starch and produces no color in rye and wheat. Treated with vesuvin (1 part strong soln. + 9 parts H_2O , time 1.5–2.0 min.), then with methylene blue (not the reverse), colors potato starch olive green; the others remain colorless. The best results are obtained by treating with a strong soln. of thionine + 2 parts H_2O , allowing 2.5–3 min. to color. Potato starch is transient lilac; the others are colorless. In cases where freshly cooked potatoes, instead of the meal, have been added the starch grains may have been destroyed by the above method, and if few are visible several crumbs are taken from different parts of the bread, placed on an object glass, moistened with H_2O , carefully pressed without rubbing with a spatula, excess H_2O removed with blotting paper, a few drops thionine soln. added and removed with blotting paper after 2–3 min. A few drops H_2O are added and sucked off with blotting paper. This washing is repeated and the coloring removed as completely as possible, a cover-glass laid on and pressed down carefully and the sample examd. with a low power. The so-called paste cells are now easily distinguished by a red color. J. H. MOORE.

Crude fiber estimation by the "Weender" method. R. FANTO AND W. NIKOLITSCH. Vienna. *Z. anal. Chem.* 54, 73–6(1915).—The ordinary method for crude fiber is modified by using paper extn. thimbles in place of linen or glass wool filters. The washing is carried out by dipping the thimble in a beaker of distd. H_2O , which in passing through the walls into the thimble washes off the fine fibers and keeps the walls clean and fast-filtering. Results given agree with those obtained by the usual method. G. W. M.

A further study of the variation in weight of a fifty pound sack of flour during storage. T. SANDERSON. *North Dakota Special Bull.* 3, No. 15, 250–9(1915).—The

normal moisture content of flour in N. Dakota is about 11.0%, and of wheat, about 13.0%. S. concludes that wheat with normal moisture 13.0% with not to exceed 2.0% added moisture in tempering will produce a flour with moisture content of about 11.0%, that will not vary in storage more than 2.0% and that the variation is as likely to be above as below the original wt., owing to atm. conditions.

EDWARD BARTOW.

Rapid method for determining magnesium in water. F. J. ANDREW. *Chem. Analyst* 12, 18-20(1915).—Det. Ca by pptg. as CaC₂O₄ and titrating with KMnO₄. Estimate total hardness with soda reagent. Express both as p. p. m. CaCO₃, and express the difference, which is due to Mg, in terms of CaCO₃. The result multiplied by 0.8432 gives true MgCO₃. Gravimetric method (Mg₂P₂O₇) on 3 natural waters gave 14.88, 36.00 and 37.50 p. p. m. MgCO₃. Corresponding values by above method are 14.82, 38.60, 38.20.

H. M. LANCASTER.

Tables for the calculation of the magnesium chloride content of river waters. H. FISCHER. *Pharm. Zentralhalle* 56, 73-5(1915); through *Chem. Zentr.* 1915, I, 705.—F. employs Zink and Hollandt's modification of Hyer's method for the detn. of MgCl₂ (*C. A.* 8, 973, 2436, 3335); evap. 200 cc. H₂O to dryness on water bath, dry 2½ hr. at 105°, ext. residue with abs. alc. 3 times, filter, wash, evap. on water bath,

add hot H_2O to residue, then add NH_4Cl and proceed as in sepn. of Ca and Mg. A table gives the amts. of Mg and $MgCl_2$ corresponding to the different amts. of $Mg_2P_2O_7$ found.

C. O. EWING.

Water analysis and the nitrogen content of water. WILLIAM M. BOOTH. *J. Am. Water Works Assoc.* 2, 61-4(1915).—Supplement to and correction of a previous paper (C. A. 8, 3335). From 129 analyses tabulated in the previous paper the author concludes: "Many natural waters of central New York contain N in all of the forms reported in the analytical scheme," (free and albuminoid NH_3 , NO_2 , NO_3 .) "Water containing sewage is in a highly unstable condition as regards the form in which the N is found. Records should be kept showing the N content of potable waters, and weekly, if possible daily, tests should be made. No quant. relationship exists between the N of water and the bacterial content. The presence of NO_3 in water ordinarily free from this form of N must be regarded with suspicion. If nitrates are present in water above 1 part per mil., it may have an unwholesome source." W. D. COLLINS.

Stripping water works reservoirs. ALLEN HAZEN AND G. C. WHIPPLE. *Eng. News* 73, 858-60(1915).—Logarithmic probability paper has been used to plot the growth of organisms in stripped and unstripped reservoirs. The stripped reservoirs show no advantage over the unstripped. The methods of study are outlined with data on the Boston and New York water systems.

LANGDON PEARSE.

Is it possible to infect water supplies artificially? VON WASSERMANN. *Das Wasser* 10, 724-5(1914); *Wasser u. Abwasser* 9, 221-2(1915).—The possibility of causing extensive epidemics by infecting water supplies artificially with cultures of cholera and typhoid bacilli should not be over-estimated. The multiplication of these bacteria in pure water is limited on account of the presence of the saprophytes. The filtration of surface water provides an additional safeguard.

ARTHUR LEDERER.

Damages for water-borne typhoid fever. *Eng. News* 73, 897-8(1915); *Eng. Contr.* 43, 423-4(1915).—In the Supreme Court of N. J. in the case of H. B. Jones vs. Mount Holly Water Company, the verdict of \$750 to H. B. Jones was upheld for expense and loss of time of 3 children sick with typhoid. The court held the company had a contractual duty to supply pure wholesome water.

LANGDON PEARSE.

Water supply and typhoid fever at Cumberland, Md. A. G. FOWLER AND MAX J. COULTON. *Eng. News* 73, 969-70(1915).—Abandoning the polluted Potomac river and securing a filtered chlorinated water supply from a sparsely populated drainage area, subject to sanitary inspection, has in conjunction with a reorganized health department reduced typhoid from a high record of 568 cases in 1910 to 61 cases in 1914. Five lbs. $Ca(OCl)_2$ per mil. gal. is used. The population in 1914 was 25,054.

L. P.

Endemic goiter, possible relationship to water supply. T. C. CLARK AND C. C. PIERCE. *Pub. Health Reports* 29, 939-48(1914).—All races are subject to goiter, but the people living in regions overlain by Silurian, Carboniferous, and Permian systems are most susceptible, while those living over eruptive or cryst. rocks of the Archean group, the Jurassic, Cretaceous, and post-Tertiary seas as well as all fresh-water deposits are comparatively free from goiter. Chemistry has failed to show the relationship between the dissolved salts and goiter, it being found in both hard and soft water regions. It is also thought that goitrous waters give a higher bacterial count than non-goitrous waters.

J. GAUB.

Lead poisoning. RAMBOUSEK. *Z. Kommunal-Hygiene* 5, 8-9(1914); *Wasser u. Abwasser* 9, 228(1915).—Pb poisoning is contracted through the use of snuffing tobacco, enamelled household containers, and drinking water. It is essential that the practicing physician familiarize himself with the characteristics of Pb poisoning.

ARTHUR LEDERER.

The removal of acid from water. H. MILDNER. *Das Wasser. Heft 22*, 637-41 (1914); *Wasser u. Abwasser* 9, 214 (1915).—The elimination of the CO_2 from the water is a necessity for practical, economic and hygienic reasons. The procedure of removal can be classified into two groups, the chemical and the mechanical. The chemicals employed are Na_2CO_3 , NaOH and $\text{Ca}(\text{OH})_2$. Scheelchase recommends percolation through broken marble. ARTHUR LEDERER.

The removal of oil from condensation water. H. W. KALI 8, 337 (1914); *Wasser u. Abwasser* 9, 302-3 (1915).—The condensed water is valuable for boiler feed purposes on account of its lack of incrustants and its high temp. It always contains, however, more or less mineral oil. An electrolytic method for the removal of oil is described. The water is permitted to pass among a number of electrodes. A small quantity of hard water or soda soln. is added in order to make the water conductive. The oil emulsion coagulates in the form of a fine floc. The water is then subjected to rapid filtration, resulting in a perfectly clear effluent. It is advisable to employ the process while the water is still warm. The consumption of direct current varies between 0.15 and 0.20 kw. per cu. m. of water. The cost of purification is approx. 1 pf. per cu. m. ARTHUR LEDERER.

Misbranding of Allouez mineral water. U. S. Dept. of Agr., Bur. of Chem., *Service and Regulatory Announcement, Supplement 2*, 102. *Notice of Judgment* 3583. The water was found by analysis to contain added NaCl and was therefore misbranded. A fine was imposed. E. BARTOW.

Ground water in southeastern Nevada. EVERETT CARPENTER. U. S. Geol. Survey, *Water Supply Paper* 365 (1915).—Wells, springs and other sources are described in detail. Analyses of 42 samples by S. C. Dinsmore show variations in solids from 132 to 7,355 parts per mil. The waters are classified in regard to hardness, scaling and foaming ingredients, probability of corrosion, and alkali coefficient. W. D. C.

Geology and water resources of Tularosa Basin, New Mexico. O. E. MEINZER AND R. F. HARR. Prepared in cooperation with the New Mexico Agr. Exp. Sta. U. S. Geol. Survey, *Water Supply Paper* 343, 311 pp. (1915).—Supplies for irrigation, railroad and public use, and the watering places on routes of travel are described in great detail. Of 103 samples of water from the valley fill, only 6 contained less than 500 parts of solids per mil., while 23 had more than 5000 parts. W. D. COLLINS.

Geology and underground waters of the southeastern part of the Texas coastal plain. ALEXANDER DEUSSEN. U. S. Geol. Survey, *Water Supply Paper* No. 335, 365 pp. (1915).—Analyses of 78 spring and well waters are classified by R. B. Dole according to principles discussed (pp. 100-106), as to mineral content (high or low), chemical character, suitability for boilers, for irrigation, for domestic use and the possibility of improvement by softening. Geology, hydrology, and well data, with many well logs and figures for amount of supply, are given in full for each county. W. D. C.

Use of liquid chlorine at Buffalo water works intake. H. F. WAGNER. *Eng. News* 73, 856-7 (1915).—Liquid Cl applied in doses less than 0.36 p. p. m. reduces bacterial count to numbers between 5 and 56 per cc. The method of application is described, including heating coils and absorption towers. LANGDON PEARSE.

The Cincinnati water works. JOHN W. HILL. *J. Am. Water Works Assoc.* 2, 42-60 (1915).—Historical sketch from 1799 up to the present time. W. D. C.

Brass screen between sand and gravel eliminated in Cincinnati filter reconstruction. J. W. ELLMS. *Eng. Record* 71, 581-2 (1915).—Breaks caused by corrosion of brass screen between sand and gravel necessitated frequent and costly repairs. New plan uses graded layer of heavier gravel without screen. FRANK BACHMANN.

Operations of the Cincinnati water filtration plant in 1914. J. W. ELLMS. *Eng. News* 73, 855-6(1915).—The settling basins removed 74.1% of the turbidity, which averaged 120 p. p. m. The coagulating basins received a turbidity of 31 and delivered 5 p. p. m. to the filters. 20.4 p. p. m. of FeSO_4 were used with 11.4 p. p. m. of CaO . The wash water averaged 2.24% with an av. period of filter service of 19.5 hrs. The filtered water contained an average of 36 bacteria per cc.; this was reduced 83.6% by liquid Cl applied at the rate of 0.1 p. p. m. The typhoid death rate was 5.71 per 100,000. Seventy % of the cases were contracted outside the city. The cost of operation and maintenance of filter plant was \$3.31 per gal. LANGDON PEARSE.

Dry-feed apparatus solves Ithaca's coagulant problem. HENRY N. OGDEN. *Eng. Record* 71, 586-7(1915).—On account of operating difficulties, dry-feed coagulant app. was substituted for the equipment which applied the chemical soln. F. B.

New sedimentation basin will halve costs of sand cleaning at Philadelphia filters. FRANCIS D. WEST. *Eng. Record* 71, 591-3(1915).—The sedimentation basin will have a capacity of 100 million gal. It will greatly relieve the turbidity load, prevent algae growths, and increase the output of filtered water. Alum will be used when the turbidity of the raw water reaches 50. The use of alum will reduce the number of bacteria applied to the pre-filters by 50%. The basin will be operated on a fill and draw plan. FRANK BACHMANN.

Water coagulation, sedimentation and aeration plant at Norristown, Pa. S. C. CORSON. *Eng. News* 73, 853(1915).—Aeration is secured by inclined planes, with projections 4 in. above surface. LANGDON PEARSE.

The Alliance water filters. THOMAS FLEMING, JR. *Eng. News* 73, 812-4(1915).—This is a rapid filter plant supplying 4.5 mil. gal. daily to 16,000 population. The raw water varies in turbidity from a few to several thousand parts per mil. The novel feature is a complete false bottom under the strainer system in the filters. L. P.

Chemical and bacterial control of the water supply of Breslau (Germany). LÜHRIG. *Intern. Z. Wasserversorgung* 1, 291-3(1914); *Wasser u. Abwasser* 9, 202(1915).—A chemical analysis of the Oder water is made quarterly. A branch lab. was installed at the pumping plant for daily tests, since the compn. of the ground water is subject to sudden fluctuations. ARTHUR LEDERER.

Iron removal plant of the waterworks at Flensburg (Germany). G. OESTEN. *Wasser u. Gas, Heft* 1-2(1914-15); *Wasser u. Abwasser* 9, 211-2(1915).—The Fe in the water supply is removed in the open type of plants (Oesten type). A. LEDERER.

An extraordinary growth of algae in the drinking water of Dublin, Ireland. JOHNSON. *Intern. Z. Wasserversorgung* 1, 187-9(1914).—Oscillatoria appeared in the Dublin water supply; they imparted a bad taste and odor to the water. J. tried CuSO_4 , after Moore and Kellermann and found that it, in amts. which were harmless, was an active destroyer of these organisms. F. W. TANNER.

The elimination of algae from the Dublin reservoirs and filters. JOHNSON. *Intern. Z. Wasserversorg.* 1, 216-8(1914); *Wasser u. Abwasser* 9, 295(1915).— CuSO_4 in dilns. of 1:100,000 up to 1:1,000,000 has been employed. For a time the decaying algae gave rise to a disagreeable taste and odor. Fish life has not been harmed. A. LEDERER.

The water supply of Rome (Italy). TITO GIARDI. *Intern. Z. Wasserversorg.* 1, 307-8(1914); *Wasser u. Abwasser* 9, 298(1915).—Rome has 4 well-water conduits, the Aqua vergine, Felice, Paolo, and Pia Marcia. The water of the 2nd conduit is bacterially less satisfactory than that of the 1st. The water of the Paolo conduit is even less satisfactory. The conduit Pia Marcia is the most modern of the 4. A. L.

Ozonization of the Pregel River water at Koenigsberg (East Prussia). KARL KISSKALT. *Gesundh. Ing.* 38, 195-9(1915); *J. Gasbel.* 58, 155-7(1915).—The water is first coagulated with alum and then ozonized. The ozonization app. (de Frise system) was furnished by the Ozongesellschaft in Berlin. The results were excellent. The resulting water is sparkling, tasteless, and nearly sterile. If no alum is applied, the amount of O_3 must be increased as the water is somewhat turbid. A. LEDERER.

The water supply of Annecy in Upper Savoy. G. THIEM. *Intern. Z. Wasserversorg.* 1, 255(1914); *Wasser u. Abwasser* 9, 297(1915).—The city has a population of 13,000. It is supplied by well and lake water. The latter is purified in Jewell filters.

ARTHUR LEDERER.

Royal commission on sewage disposal. Ninth and Final Reports. *Surveyor* 47, Supplement, Apr. 2, 1915; No. 1211, 12 pp.—The final report, given practically *in extenso*, consists of summaries made by the commission of each of the 9 reports published from 1901 to 1915. W. D. C.

Determination of the biochemical oxygen demand by the saltpeter method in stockyards, tannery and corn products wastes. A. LEDERER. *J. Ind. Eng. Chem.* 7, 514-6(1915).—The method can be used without modification with packing house waste mixed with domestic sewage but must be modified for corn products wastes. The method is not readily applicable to tannery wastes. ISADOR MILLER.

The determination of dissolved oxygen in polluted waters. L. W. WINKLER. Budapest. *Z. Nahr.-Genussm.* 29, 121-8(1915); cf. *C. A.* 9, 674.—W. has modified his original method so that the presence of nitrites and moderate amts. of organic matter do not interfere with its accuracy. The modification consists in the addition of a soln. of chlorinated lime and dil. H_2SO_4 to the water at the time of sampling, the excess of $CaOCl_2$ being destroyed immediately before titration by means of $KCNS$. Fill a 250 cc. sample bottle almost completely with the water and add 10 drops (0.5 cc.) each of $CaOCl_2$ soln. and 50% H_2SO_4 , stopper and shake. The sample may then be reserved until any convenient time within 24 hrs. for analysis. The $CaOCl_2$ soln. is prepd. by rubbing 1 g. of fresh chlorinated lime (about 30% available Cl) with 100 cc. of $Na_2SO_4 \cdot 10H_2O$ (25 g. per 100 cc.) and filtering the mixt. If the $CaOCl_2$ treatment is performed in the lab., at least 10 min. must be allowed before proceeding with the detn. Then add 2 cc. $KCNS$ (1 g. c. p. *white* $KCNS$ in 200 cc. 25% $Na_2SO_4 \cdot 10H_2O$), shake, and allow the mixt. to stand for 10 min. Add 1 cc. $MnSO_4$ soln. (1 part $MnSO_4 \cdot 4H_2O$ and 2 parts water) and 2 cc. of KI - $NaOH$ soln. (2 parts $NaOH$, 1 part KI and 4 parts water) and 5 cc. of 50% H_2SO_4 , or, if the water is very cold use 10 cc. of the last reagent. When much Fe is present in the water use 5 cc. of 50% H_3PO_4 instead of the H_2SO_4 . Titrate with 0.01 N $Na_2S_2O_3$. For the sake of uniformity this method can be applied to all kinds of waters except those heavily polluted with organic matter. In such cases only the gasometric method can be used. Introduce 10 g. of granulated marble, that has previously been freed from dust by sifting, into a 500 cc. bottle, and cover with a little acidified (HCl) water. When active evolution of gas begins pour off the dil. acid and then allow the water under exam. to flow through the bottle until the interior, including the marble fragments, is thoroughly washed. Then fill to the neck with the water and close with a one-hole stopper fitted with a cylindrical bulb (of 20 cc. capacity) the lower end of which communicates through the stopper with the contents of the bottle and the upper end of which bears an opening which may be fitted with a stopper and a capillary delivery tube for conducting the dissolved gases into a eudiometer. The stopper and bulb tube are fitted into the bottle containing the water in such a way that no air space remains below the stopper and the water rises to a height of about 8 mm. in the bulb tube. If the amt. of water in the bottle is insufficient for this purpose, add enough satd. $CaCl_2$ soln. (air-free) to accomplish it. Then fill the

bulb tube to the neck with concd. HCl, add a layer (1-2 cc.) of water and fit a capillary delivery tube into the neck of the bulb. Place the large bottle in a capacious vessel containing water at 15°, since this is the best temp. for controlling the evolution of CO₂. In a short time the HCl reaches the marble and CO₂ is generated; this carries with it the dissolved air in the water. Collect the gas in a eudiometer over 20% NaOH, and when the vol. of gas ceases to increase measure in the usual way. Det. the O by absorption in alk. pyrogallol or alk. Na₂S₂O₄. Deduct 0.192 cc. N and 0.083 cc. O as a correction for the gases dissolved in the concd. HCl employed. For temps. between 0 and 30° W. has found the % of O in air dissolved in water to be $n = 34.91 - 0.0438t$, in which n = % of O in the air, and t = temp. A. F. SEEKER.

The treatment of waste waters from tin and lead mines, gut factories, and piggeries. G. BERTRAM KERSHAW. *Surveyor* 47, 404-5(1915).—Waters from tin and lead mines are successfully treated by sedimentation. Solid wastes from cleaning of sheep and pig intestines are generally fed to pigs. Liquid wastes are absorbed in the ground without much preliminary treatment. Solid manure from piggeries is easily disposed of by sale or gift. Dry weather liquid sewage (4-5 gal. per pig per day) is best treated with lime, the liquid filtered through deep percolating filters and then through shallow sand filters. It is better to dilute the tank effluent with 2 or 3 times its vol. of water and filter at a rate of 75 gal. per cu. yd. per day. W. D. C.

The action of electrolytes on effluents containing organic waste. P. ROHLAND. Stuttgart. *Kolloid-Z.* 16, 58-60(1915).—Effluents from sewers or from certain mfg. processes such as sugar refining, breweries, tanneries, dye works, etc., may be freed from their colloidal content by mixing with effluents containing inorganic salts, as from K works, when coagulation and sedimentation occurs. This at the same time removes the plankton, but not the dissolved materials. This method should be applied only after detg. the electro-positive or -negative nature of the colloid, and applying the proper electrolyte to cause coagulation. H. I. MATTILL.

Remodeling of septic tanks into Imhoff tanks eliminates odors from land irrigation. CHARLES GILMAN HYDE. *Eng. Rec.* 71, 747-8(1915).—Irrigation of lands at Orange, Cal., with septic tank sewage caused complaints of odors; these were eliminated when the tanks were converted into Imhoff tanks. Odors were due to the H₂S liberated from the septicized sewage after it had been spread out over the farms.

FRANK BACHMANN.

Electrolytic sewage purification. E. O. RASSER. *Staedtereinigung* 1914, 153; *Wasser u. Abwasser* 9, 295(1915).—The article deals with the disinfection of sewage with hypochlorites, electrolytically prepd. from NaCl. The expts. proved the deodorizing and disinfecting value of these compds. ARTHUR LEDERER.

More recent English sewage purification plants. A. H. OP TEN NOORD. *Ingenieur* No. 52(1914); *Gesundh. Ing.* 38, 185-90(1915).—The plants at Wakefield, Huddersfield and Bradford are described. Wakefield is a town of approx. 50,000. The dry weather flow is 9000 cu. m. per day, 60% of which consists of wool-dyeing, wool-washing, brewery and chem. factory waste. The sewage passes first through a grit chamber. Lime is added as a coagulant and the settled liquid is biologically treated on filters of the Dunbar type. Secondary settling basins are provided for. The final effluent reaches the Calder river. The sludge is dried on land. This has led to a nuisance. 50% of the Huddersfield sewage is contributed by the textile and metal industries. The total dry weather flow is 13,630 cu. m. per day. One of the disposal plants is in Deighton, the other in Cooper-Bridge. In Deighton the sewage is screened and settled. The settled sewage is pumped to the Cooper-Bridge plant for biological treatment. The results obtained with the fat extn. from the sludge at Deighton are

not made public. The sewage of Bradford contains unusually large quantities of wool fat. There are 2 plants at Bradford. At Frizinghall the sewage is treated with H_2SO_4 and the liquid, freed from sludge and scum, is permitted to reach the Aire river. In Esholt the sewage passes a grit chamber and self-cleaning screen. A max. of 136,000 cu. m. is treated daily with H_2SO_4 . It is planned to treat this effluent biologically. The sludge is heated to 100° and the fat separates. The residual sludge is mixed with lime and pressed into briquets. The fat is further purified with H_2SO_4 and filled into barrels.

ARTHUR LEDERER.

Sewage disposal in Chilliwack. D. P. DUNN. *Munic. J.* 38, 687-9(1915).—The plant handles 2500 population. The novel feature is a settling tank with 20 weirs in each compartment, skimming the effluent.

LANGDON PEARSE.

Sewage treatment for Philadelphia. *Eng. Contrg.* 43, 460(1915); *Munic. J.* 38, 695(1915).—The plans proposed divide the city into 3 drainage areas. For 2 areas, treatment is recommended with coarse screens, grit chamber and 2-story tanks. For the third area, fine screening is substituted for the tanks. The project will cost \$500,000 annually for the next 5 yrs. The operation and maintenance will cost \$500,000 per year, and \$2,000,000 will be required for new sewers annually. The purpose is to provide a clean sanitary harbor and protect the public health.

LANGDON PEARSE.

Sewage treatment plant at Calvert, Texas. T. L. FOUNTAIN. *Eng. News* 73, 930-4(1915).—This small plant serving 1500 population cost \$5,000. It comprises bar screens, 2-story settling tanks (2-hr. period with sludge storage 560 cu. ft.), sludge bed (1144 sq. ft.), sprinkling filter (5 ft. deep) with splash plate distribution, a final sedimentation basin (2-hr. period) holding 150 cu. ft. sludge and disinfection rig. No odor is noted 20 ft. away. One man spends 45 min. a day at the plant. The sludge dries readily.

LANGDON PEARSE.

Design and operation of small municipal refuse incinerator at International Falls, Minn. E. W. KIBBY. *Proc. Minnesota Surveyor and Engineer*; *Eng. Contrg.* 43, 477-8 (1915).—Mixed refuse is burned. The cost was \$1600, to serve 4000 population.

LANGDON PEARSE.

The degree of purification desirable and practicable in sewage treatment plants in Iowa. L. HIGGINS. *Iowa Eng. Soc.* 1915; *Eng. Contrg.* 43, 479-80(1915).—H. recommends a non-putrescible effluent, with disinfection if circumstances demand. Various methods of detg. putrescibility are discussed.

LANGDON PEARSE.

Municipal garbage reduction plant, Schenectady, N. Y. S. GERTZ. *Eng. News* 73, 820-2(1915).—The reduction plant is on the Chamberlain system and handles 20 tons of garbage daily from 90,000 population. The pressing is accomplished in the digesters immediately after cooking. The tankage is washed with naphtha, dried and shipped.

LANGDON PEARSE.

Imhoff tanks and sprinklers for sewage of Brighton District, Rochester, New York. ANON. *Eng. Rec.* 71, 679-82(1915).—The present population is 3,000. Screens and grit chambers are to be built for the final max. population 25,000, but Imhoff tanks, sludge-drying beds and sprinkling filters and secondary sedn. tanks are to be large enough for only 10,000 people. The remaining units will be built when required. Plans of the disposal works and an engineering description accompany the article.

FRANK BACHMANN.

The technical equipment of the emigration quarters of the Hamburg American Line at Hamburg. ENDRIS. *Gesundh. Ing.* 38, 133-41(1915).—A detailed discussion of the general layout, the machinery and boiler equipment, the disinfection plant, the kitchen and the sewage disposal plant. The sewage is settled and disinfected.

ARTHUR LEDERER.

The use of copper sulfate in the purification of swimming pools. S. J. THOMAS. *J. Ind. Eng. Chem.* 7, 496-9(1915).—T. advocates the use of CuSO_4 . It has the advantage over $\text{Ca}(\text{OCl})_2$ that it does not undergo chem. change which destroys efficiency. It is not irritating to eyes and mucous membranes, is cheaper and is odorless.

ISADOR MILLER.

The necessity of ventilation. MEYER J. STURM. Chicago. *J. West. Soc. Eng.* 19, 233-58(1914).—Expts. by the Chicago Comm. on Ventilation show that CO_2 does not settle out of expired air. The allowable amt. is given by the expression $\text{CO}_2 = (6000/A) + 4$, where A is the number of cu. ft. of air per hr. per cap. Relative humidity, supplied when necessary as steam, should be maintained between 40% and 75%. The "Comfort Zone" is between 64° F. with relative humidity 55% and 70° F. with relative humidity 30%; 64° F. with relative humidity 30% seemed best. The better death rate showing of the more northern cities as compared with the southern is thought to depend largely on the outdoor life in the southern climate and the better ventilation of the southern buildings.

W. B. JOHNSON.

An experiment with ozone as an adjunct to artificial ventilation. A. M. FELDNER. *Heating Vent. Mag.*, March, 1915, 35-6.—Ozone eliminated odors in hospital room containing patients being treated for gastro-enteritis.

H. V. MAIN.

The use of ozone for disinfection of air. B. GALLI-VALERIO. *Centr. Bakt. Parasitenk., Abt. I* 75, 93-6(1914).—G. gives results obtained by using O_3 to sterilize the air in a small room. The temp. was 15-16° and the humidity 60-15. G. exposed cultures of *B. coli* and *M. pyogenes albus* dried on pieces of glass for 5, 6 and 9 hrs. No killing nor inhibition of the bacteria was obtained. The expt. was repeated and in each case the same results obtained. G. warns against the use of ozonators to sterilize air in rooms.

FRED W. TANNER.

The new disinfection plant of the Fortress Cracow. F. A. EBERT. *Gesundh. Ing.* 38, 182-5(1915).—The disinfection app. which is to be installed permits alternating disinfection with steam under pressure and HCOH in *vacuo*. A. LEDERER.

State laws on removal of dust. H. C. ESTEP. *Iron Trade Rev.* 56, 415-22(1915).—Discussion and abstracts of laws prescribing effective dust removal systems.

Brit., 2,150, Jan. 27, 1914. F. L. E. M. SIGNORET. In fumigating casks, etc., S to be burned is made into blocks by mixing powdered S with Na or K silicate soln.

Brit., 2,626, Jan. 31, 1914. C. P. LANDRETH. App. for purifying river or waste water or other liquids is provided with means for agitating the liquid between stationary electrodes and maintaining these free from bubbles or deposits. A part only of the liquid may, after addition of a salt, be passed through the app., and subsequently mixed with the main body of liquid. Softening agents may be added after electrolysis; 1 set of electrodes may be cut out of circuit so as to act merely as baffles for distributing these agents through the liquid. An elec. motor may drive both the agitator and 1 or more dynamos feeding the electrolyzer through an adjustable resistance. Superposed a. c. and d. c., the former predominating, may be used; the dynamos may be in parallel or series, and protected respectively by a series condenser and series inductance in the former case, and by a shunt inductance and shunt condenser in the latter case. The current may be periodically reversed.

15. SOILS AND FERTILIZERS.

M. X. SULLIVAN.

The absorption of ultraviolet and infra-red rays by arable soil. J. F. TRISTAN AND G. MICHAUD. *Arch. sci. phys. nat.* 39, 270-3 (1915).—The absorptive power of soils for the ultraviolet and infra-red rays was detd. by means of photographs with the use of appropriate filters. For the infra-red the wet soils have a greater absorption than the dry soils. This difference is less for the ultraviolet. Dry clay soils in ultraviolet light appear black while in infra-red they appear white.

M. X. S.

Absorption of cations and anions by the soil. A. DE DOMINICIS. *Stas. sper. agrar. ital.* 47, 449-73 (1914); through *Chem. Zentr.* 1915, I, 391-2.—Cations are without exception absorbed by the soil, as are also the anions. In certain expts. negative absorption of Cl^- and NO_3^- was observed, yet other expts. showed that also these were absorbed as much or more than the cations. Anion absorption is a case of formation of insol. substances, and indeed anions are absorbed by positively charged, cations by negatively charged, amorphous soil constituents. The degree of absorption increases with the valence of the ions. The absorption of the cations and that of anions is the same for all soils, whereas the total absorption varies, and depends on the nature of the soil colloids and the soil soln.

L. J. GILLESPIE.

The determination of nitric nitrogen in soils. E. R. ALLEN. *J. Ind. Eng. Chem.* 7, 521-9 (1915).—Reduction with Devarda's alloy in MgO solns. and the Al reduction method do not give reliable results in the presence of much org. matter. With the former method reliable results are obtained in solns. 0.1 N in NaOH even in the

presence of much org. matter. This is the best concn. The Mitscherlich app. is the best distn. app. for this method.

ISADOR MILLER.

Loss of nitrogen and organic matter in cultivated Kansas soils and the effect of this loss on the crop-producing power of the soil. C. O. SWANSON. *J. Ind. Eng. Chem.* 7, 329-32 (1915).—Analyses of cultivated and uncultivated soils show that the former have lost 1200-1800 lbs. N and 32,400-49,600 lbs. org. matter per acre in the surface soil. This is 22.6-43.5% N and 23.3-51.3% org. matter. By "loss" is meant the difference in wt. of N or org. matter, over an area of 1 acre and to a depth of 7 in., found in virgin soil and in cultivated soil.

ISADOR MILLER.

Investigation of the content of mineral soils in acid and alkaline substances. A. STUTZER AND W. HAUPT. *J. Landw.* 63, 33-45 (1915).—The qual. test of Baumann and Gully (*Naturw. Z. Land- u. Forstwirtschaft* 1908, 1) has been developed into the following quant. method for the detn. of acids: Dry 40 g. soil, at 100°, pulverize, sieve, put into a glass-stoppered $\frac{1}{2}$ l. flask, add 50 cc. of 2% KI and 50 cc. of 0.5% KIO₃ (in CO₂-free water), shake 15 minutes, dil. the contents with 300 cc. CO₂-free H₂O, mix and filter through a Gooch. Discard the first 50 cc. and titrate 300 cc. with 0.01 N Na₂S₂O₄ with starch indicator. 1 cc. of thiosulfate = 0.00001 g. H⁺. In a test of the method on 11 soils, no relation was found between the acidity and the CaCO₃ content. The content of sol. alk. substances can be detd. by titrating 300 cc. of a 10% aq. ext. of soil to which 25 cc. of KI and KIO₃ solns. and 25 cc. 0.01 N H₂SO₄ have been added.

L. J. GILLESPIE.

The number and growth of protozoa in soil. J. M. SHERMAN. *Centr. Bakt. Parasitenk., Abt. II* 41, 625-30 (1914); *Bull. Agr. Intelligence* 5, 1165-6.—By examg. 16 soils it was detd. that normal fertile soils contain approx. 10,000 protozoa per g. Flagellates constitute the principle protozoa fauna of the soil.

J. J. S.

Studies on the influence of the condition of the soil on bacterial life and the exchanges of material produced by the latter. H. R. CHRISTENSEN. *Centr. Bakt. Parasitenk., Abt. II* 43, 1-166 (1915).

JULIAN H. LEWIS.

Soils of the cut- and burned-over areas of North Idaho. J. S. JONES AND C. W. COLVER. Idaho Agr. Expt. Sta., *Bull.* 81, 20 pp. (1915).—Analyses of a number of soils are given showing the amts. of N, Ca, Mg, P, K and S in the first 9 inches of soil. Data are also given showing the effect of lime and N-carriers on crop growth.

B. E. B.

Studies on the agricultural value of silt carried from streams of the Alps and Pyrenees. A. MÜNTZ AND E. LAINE. *Compt. rend.* 160, 491-5 (1915).—Physical and chem. analyses of the deposits of the different sections bordering the irrigation canals are given.

J. J. SKINNER.

The antizymotic action of a harmful soil constituent: Salicylic aldehyde and mannitol. J. J. SKINNER. *Plant World* 18, 162-8 (1915); cf. *C. A.* 9, 115.—The simultaneous occurrence of mannitol and salicylic aldehyde in a soil is pointed out. In a nutrient soln. growing wheat seedlings mannitol was harmful in solns. where decompn. took place and was slightly beneficial in the solns. where there was no decompn. Salicylic aldehyde in a culture soln. with mannitol prevented any decompn. It is pointed out that the existence of mannitol in a soil is made possible by the simultaneous presence of salicylic aldehyde. Without the presence of an antiseptic agent mannitol could not exist in soils.

J. J. S.

Method of determining the lime requirement of soils. C. H. JONES. *Am. Fertilizer* 39, No. 11, 28-29 (1913).—Add 0.5 g. Ca acetate (tested reagent) to 5.6 g. of soil, place in a 3 in. mortar, and mix. Add sufficient water (room temp.) to make

a fairly stiff paste. Pestle for 20 secs., add 30 cc. water, and continue mixing for 30 secs. Wash into a 200 cc. flask and keep bulk down to about 160 cc. Let stand, with occasional shaking, for 15 min. Make up to bulk of 200 cc., mix, and filter through a dry filter. Discard first 10 to 15 cc., which may be cloudy. Titrate 100 cc. of the clear filtrate, using phenolphthalein with 0.1 *N* NaOH. This reading, multiplied by 2 gives the number of cc. of 0.1 *N* alkali required to neutralize the acetic acid in 200 cc. of the soln. This figure times the factor 1.8 times 1000 equals the lbs. of CaO required per 2,000,000 lbs. of soil. Or multiply the number of cc. of 0.1 *N* NaOH by 3600. "The factor 1.8 is a tentative one only, having been secured on a relatively small number of samples representing Rhode Island, Mass., Vermont and New Jersey soils. The method is extremely rapid, one man easily making 50 detns. in a day."

B. E. B.

Injurious nitrogen transformations in bog soils as a result of the action of large lime applications. T. ARND. *Landw. Jahrb.* 47, 371-442(1915); *Chem. Zentr.* 1915, I, 701-2.—Expts. carried out with numerous bog soils lead to the following conclusions: In consequence of the unfavorable conditions for microorganisms found in untreated acid peats, no bacterial decompn. of saltpeter takes place, but in peats neutralized or rendered alk. by lime an energetic reduction of nitrates takes place with considerable loss of nitrate and total N. The N losses are dependent on the amt. of lime applied. The fact that small temp. differences produce large variations in the denitrifying reaction is looked upon as a proof that the reaction is biological in its nature. In each class of bog soils, the microbiological reduction of nitrates increases with the state of decompn. and the action is stronger in low-lying peats than in the higher ones. The results obtained support the assertion of Tackes that the injurious action of strong liming is caused by unfavorable bacterial N decompns. Liming greatly improves the soil as a medium for microorganisms. When bog soils which have not been treated with N fertilizers are limed, some of the soil N is removed and when a peat fertilized with NaNO_3 is limed, part of the N is lost through reduction to nitrite and another part through denitrification. In either case a decrease in the crop yields will result.

C. F. MILLER.

Analyses of guanos. Pozzi-Escot. *Ann. chim. anal.* 20, 99-101(1915).—Discussion of a paper by Hutin (cf. *C. A.* 9, 684). Contrary to the impression given by H., the Peruvian guanos are in general use in Peru, the results being successful from an economic viewpoint. The richest guanos (of recent formation) contain 12-13% N, the older, 3 to 7% N; guanos of less than 3% are not exploited in Peru, but are exported when high in P_2O_5 , and contain less than 50% of insol. matter (SiO_2). The low-grade guanos are high in NaCl (up to 21%). All guanos containing over 30% of insol. matter (sand) are classed as poor or low grade. The H_2O content is generally 7-9%, only rarely as low as 4%.

F. W. SMITHER.

Germany's provision with fertilizers. B. RASSOW. *Z. angew. Chem.* 28, 196-201 (1915).—The author gives statistics on the consumption of each of the important fertilizer materials used for agricultural purposes in Germany in recent years, and the prospects of the demands being supplied during the war. There is plenty of K_2O . By making extensive use of Thomas slag-meal cyanamide and $(\text{NH}_4)_2\text{SO}_4$, R. believes that Germany can satisfy her fertilizer needs.

C. F. MILLER.

The influence of calcium cyanamide on the germination of barley and wheat. R. TRNKA AND B. MYSIK. *Z. landw. Versw.* 18, 58-63(1915).—Tests were made with various quantities of CaCN_2 on a sandy loam of moderate humus content, applied various lengths of time before sowing. In the quantity usually applied, CaCN_2 exerted no lasting injurious effects, even when applied on the day of sowing.

L. J. GILLESPIE.

Experiments on the action of certain humus preparations, especially the so-called humus-silicic acid, on vegetation. E. HASELHOFF. *Landw. Jahrb.* 47, 345-69(1915); *Chem. Zentr.* 1915, I, 702-3.—The humus preps. exert a fertilizing action by virtue of the plant food contained in them, but the humus-forming substances as such do not play a significant role.

C. F. MILLER.

Experiments on the influence of potassium ferrocyanide on vegetation. E. HASELHOFF. *Landw. Jahrb.* 47, 338-44(1915); *Chem. Zentr.* 1915, I, 702.—Expts. showed that the injurious action begins at a concn. of 0.1 g. of $K_4Fe(CN)_6$ per l. and that it is very pronounced when a nutrient soln. contg. 0.5 g. per l. is used.

C. F. MILLER.

The valuation of commercial arsenate of lead. R. H. ROBINSON AND H. V. TARTAR. *J. Ind. Eng. Chem.* 7, 499-502(1915).—Detns. were made on 6 samples of com. arsenate of lead of moisture, total As_2O_3 , total PbO , $PbHAsO_4$, H_2O -sol. As_2O_3 and PbO , $PbCO_3$, H_2O -sol. impurities, chlorides, sulfates, acetates and acid-insol. impurities. New methods were devised for detg. $PbHAsO_4$ in the presence of mixed salts, and for detg. $PbCO_3$, H_2O -sol. As_2O_3 and H_2O -sol. impurities, acid-insol. impurities and chlorides; also for the detection of acetates.

ISADOR MILLER.

"Perocid" as a substitute for copper sulfate in combating *Peronospora* of the vine. FR. GVOZDENOVIC. *Z. landw. Versw.* 18, 11-28(1915).—"Perocid I" or simply "Perocid" is a by-product of gas-mantle manuf. It is a mixt. of sulfates of the rare earth metals (chiefly Ce, Nd and La) together with small quantities of Yt, CaO, Fe_2O_3 and SiO_2 , as impurities. The earth-metal sulfates make up (as oxides) 50%, the SO_3 36.5%, H_2O 12.5%, and the rest is the impurities named. For use it is dissolved in H_2O and made alk. to phenolphthalein with $Ca(OH)_2$. The soln. keeps for months, cannot clog up spraying machines, and does not require agitation during spraying. A 3% soln. is recommended, and this is expected to be 15% cheaper than 2% Bordeaux mixt.; the tests here reported show it is more effective than the latter. Perocid II and III are already neutralized preps. and were found of no practical use.

L. J. GILLESPIE.

Copper sprays. H. FONZES-DIACON. *Compt. rend.* 160, 528-30(1915); see C. A. 9, 565.

J. J. S.

Effect of cyanide of potassium on trees. C. H. SHATTUCK. Univ. Idaho. *Science* 41, 324(1915).—KCN is recommended as an insecticide, and the charge that it causes the death of trees, when used for the above purpose, is denied.

W. A. PERLZWEIG.

Hydrocyanic acid content of sorghum (WILLAMAN) 12.

Brit., 2,998, Feb. 5, 1914. G. BECCARI. Addition to 7,946, 1912 (C. A. 7, 3183). The incubation tower and manure chambers described in the principal patent are fitted with horizontal cooling pipes for the condensation of H_2O and salts of NH_4 . Lateral chambers are provided for the cooling medium which in the case of the upper set of cooling pipes may be H_2O . The heat of the fermenting mass in the chambers may be used to heat pipes leading to buildings, fowl houses, drying app., etc., or by direct contact, to heat boilers, saucepans, etc. The heating pipes referred to may be led to a drying shed having a perforated floor. Lead boxes containing dil. H_2SO_4 or HCl may be placed on the diaphragm of the tower. One overflows into another, and finally the liquid is discharged into a funnel. In cold places, the tower may be replaced by horizontal passages having openings with covers and leading to a vertical shaft furnished with condensers.

Brit., 3,074, Feb. 5, 1914. E. CISELET and C. DEGUIDE. Phosphate. See Fr., 468,042 (C. A. 9, 1364).

Ger., 281,296, Oct. 28, 1911. ACT.-GES. PEINER WALKWERK and H. KÜPPERS. Process of increasing the citric acid solubility of phosphatic slags by the addition of silicious matter. The known method of adding sand, in a stream, to the slag as it is being poured into the slag cars, is unsatisfactory, because a uniform mixt. of sand and slag does not result. According to the present process, the slag is discharged, with great care, i. e., slowly (8-10 mins.), to avoid admixt. of Fe, into the slag car. To an average slag charge of 7000 kg., from 400 to 600 kg. sand must be added during discharge. The car is run then to a stirring mechanism by which the sand and slag are intimately mixed. The stirring arms are forced through the solid crust of slag and the resulting pieces are thrown violently against the sides and bottom of the car, thereby aiding greatly in the mixing operation. After about $3\frac{1}{2}$ mins. constant stirring the mass solidifies to a tough, dough-like form, which is voluminous and contains numberless bubbles. The citric acid solubility is increased by this treatment up to 99%.

ROBERT WAHL.

The present status of the chemical examination of wine. T. PAUL. Munchen. *Z. Nahr.-Genussm.* 28, 509-47(1914).—P. indicates the unsatisfactory nature of the present official method for detg. total acidity of wines, pointing out the discrepancies sometimes found between the relative acidities as detd. by titration and by taste. This discrepancy is due to the fact that in titration total replaceable H is detd., whereas the sense of taste is influenced solely by the concn. of H ions in the wine. The well-known laws controlling the dissociation of acids are given and explained, it being shown that not only the identity of the acids present but their relative proportions as well as those of the salts present in the wine operate to alter the concn. of H ions. The work of Quartaroli, Dutoit and Duboux, and v. d. Heide and Baragiola (C. A. 8, 2023) is freely cited upon the physico-chem. exam. of wines (see also Baragiola and Boller, C. A. 8, 535) illustrating by examples how a complete analysis by these means explains differences in taste upon which customary analysis throws no light. The degree of dissociation of various acids and bases, both organic and inorganic, for different dilns. and in the presence of salts are given showing the effect of these upon the H ion concn. of wine. P. urges that the latter should be included among the regular detns. of a wine analysis expressing the result as "degree of acidity" given in mg. of H ions per l. of wine, and recommending for this purpose the method involving measurement of the speed of sucrose inversion at 76° . Destroy inverting enzymes in a sufficient amt.

of wine by heating at 76° for 30 min. Introduce 10 g. of pure, dry loaf sugar into a 100 cc. flask, dissolve it in a small amt. of the treated wine and then fill to the mark with the sterilized wine. Det. the polarization of the soln., pour into a 250 cc. Erlenmeyer flask, close the flask with a 2-holed rubber stopper in which one hole is fitted with a bent capillary tube left open during the subsequent heating to prevent development of pressure within the flask, and the other hole fitted with a short straight wide-bore tube through which the stem of a pipet may be inserted from time to time for withdrawing samples for polarization, this tube being closed with a small stopper during the heating. Fasten the flask in a suitable holder and immerse in a thermostat bath maintained at a temp. const. to 0.1° and which is in the neighborhood of 76° . Withdraw samples and polarize every 100 min. and calc. the sucrose concn. from the readings. Obtain the inversion const. from the formula $k = \log C_0 - \log C_t / 0.4343t$, in which C_0 = concn. of sucrose before inversion, C_t = concn. of sucrose after t min. inversion, and t = elapsed time in min. during which the wine has been heated with the sugar. If the temp. of the thermostat bath is not exactly 76° correct the const. so obtained by deducting 0.9% of the value of k for each 0.1° above 76° and adding the same correction for each 0.1° below 76° . To convert to mg. of H ions per l. ("degrees of acidity") divide the corrected value for k by the factor 0.00374. The degrees of acidity of 79 German white wines detd. by this method ranged between 0.17 and 1.61. A suitable thermostat for this work is described and illustrated. Methods with illustrations of app. are also given for detg. acidity by means of measurements of electromotive force and by speed of hydrolysis of ethyl acetate, these methods not being recommended for general use though applicable for control purposes. The advantages of a detn. and balancing of all anions and cations present in wine are mentioned together with the combined titration and cond. method of v. d. Heide and Baragiola (l. c.) for detg. replaceable H. Other unusual detns. (besides those of the common bases Fe, Al, Ca, Mg, K and Na) which P. considers should be made in wine are: succinic and malic acid, Zn, As, N and glycerol (propyl iodide method), together with the detection of citric, benzoic, boric, formic, and cinnamic acid, as well as F.

A. F. SEEKER.

Analysis and judgment of vermouth wine. A. VERDA. *Schweiz. Apoth. Ztg.* 53, 248-51, 260-4 (1915).—The amt. of white wine contained in this prepn. is uncertain; the minimum should be 70%. The results of analyses of 21 vermouth wines by Behre and Frerichs (*C. A.* 7, 2281), and by Jeanprêtre are recorded, sp. gr., EtOH % by vol., ext., total acid, ash, sulfates and total sugar being detd. In another table, V. reports his analyses of 7 wines and of 4 by H. Enz. Detn. of total sugar is omitted as unreliable; acids are detd. as volatile and fixed acids. The nos. for ash may be of service in judging the % of white wine added. On the basis of 1.3 g. ash per l. in white wine, an amt. less than 1 g. per l. would indicate diln. below 70%. The difference ash minus sulfates calcd. as K_2SO_4 might also furnish a limit.

S. WALDBOTT.

The certification of dessert wines. L. GRÜNHUT. Wiesbaden. *Z. Nahr.-Genussm.* 28, 586-617 (1914).—A discussion upon 2nd reading before a general meeting of German food chemists of a draught of proposed regulations embracing proper modes of production, comp. and branding of these products, the first draught having already been reported (cf. *C. A.* 8, 1184). The subject of the degree of fermentation to be required before a fortified product is entitled to the designation "wine" was fully discussed, the conclusion and decision of the assembly being that at least 6% by wt. of EtOH must be derived by fermentation. Upon this basis products containing less than 0.36% of glycerol (ratio EtOH:glycerol::100:6) are not regarded as wine. The designation of a product as "medicinal wine" or in any way indicating special curative or nutritive properties is deemed misbranding, a similar decision being made regarding

indirect references to geographical names ("Port Type," "formerly called Port," etc.) when applied to imitations of such wines as port. The amt. of 90% EtOH (cc. per l.) employed for fortifying may be calcd. from the formulas: $1.4a - 23g$ (least amt.), $1.4a - 17g$ (probable av. amt.), and $1.4a - 14g$ (greatest amt.) in which $a = g$. EtOH per l. and $g = g$. glycerol per l. The original amt. of solids (g. per l.)—least, av. and greatest—may be calcd. from the formulas:
$$\left[\frac{1000(e + 20g)}{(1000 - 1.4a + 14g)} \right] + 10,$$
$$\left[\frac{1000(e + 25g)}{(1000 - 1.4a + 17g)} \right] + 10 \text{ and } \left[\frac{1000(e + 33g)}{(1000 - 1.4a + 23g)} \right] + 10,$$
 a and g having the same values as above and $e = g$. of solids per l. of finished wine. An original solid content exceeding 300 g. per l. indicates the use of a substance of higher concn. than grape juice, while original solids exceeding 460 g. per l. indicates the use of raisins or similar substances, the absence of cane sugar or glucose being assumed in all cases. The presence of more levulose than dextrose indicates a wine in which fermentation has been checked by addition of spirits, whereas equal proportions of these sugars indicates practically complete fermentation of the original must or the use of fortified grape juice.

A. F. SEEKER.

Calculation of invert sugar contents of wine from weighed cuprous oxide or copper. J. PRITZKER. *Schweis. Apoth. Ztg.* 53, 286-8(1915).—To find the amt. of invert sugar (g. per l.) in wine according to the method of the Swiss Food Code, multiply g. of Cu_2O obtained by 0.18, or g. of Cu obtained by 0.20. This calcn. is of advantage when the table of von Fellenberg (*C. A.* 8, 835) is not available. If sugar is detd. in the sample in which ext. was previously detd. by the sp. gr. (distn. method), the process involves diln. of 10:11. The above factors will then be 0.20 for Cu_2O and 0.22 for Cu.

S. WALDBOTT.

De-acidifying of hyperacid wines. G. DE ASTIS. Arezzo. *Ann. chim. applicata* 3, 245-54(1915).—The substances employed for these expts. were KOH, K_2CO_3 , $KHCO_3$, neutral K tartrate and $CaCO_3$. The author concludes: (1) The correction of the excessive acidity in white wine by addition of a neutralizing substance, as a rule, improves the taste and the com. value of the wine. (2) The acidity, cream of tartar, ext., and d. are decreased in value, but KOH increases the amt. of sol. cream of tartar. The variations downward of the ext. corresponded to the quantities of tartaric acid removed. The ash and alkalinity were highest on addition of KOH and the other K neutralizers, but lowest with $CaCO_3$. (3) The action of each neutralizer was exerted principally upon the fixed acids, but to some extent on the volatile acids. Tartaric acid is pptd. in large part; the remaining acids are neutralized in whole or in part. (4) The K neutralizers ppt. the cream of tartar in a cryst. form, while $CaCO_3$ ppts. the neutral Ca tartrate; both ppts. may be recovered on decanting the wines. (5) The crystals of tartar from the same neutralized wine present different and characteristic forms for each neutralizer, which fact permits of the detection microscopically of the neutralizer employed. (6) $CaCO_3$ is the best neutralizer, on account of its greater economy, and because it least alters the chem. comp. of the wine. Then come $KHCO_3$, K_2CO_3 , KOH, and neutral K tartrate in order of decreasing value.

S. LEVY.

The improvement of wines of unusually poor vintages within the bounds of the existing wine law. P. KULISCH. Colmar. *Z. Nahr.-Genussm.* 28, 482-505(1914).—The vintages of the past few years having been unusually poor and a movement having been instituted to amend the existing German wine law so that 25% instead of 20% of sugar soln. can be used to improve the wine, K. discusses the probable efficacy of the proposed change in accomplishing the desired results. The cause of such defective wines lies in the high acidity (2.0-2.2%) of the musts. A potable wine should not

have an acidity greater than 0.6 to 0.8%, the addition of sugar soln. being designed to reduce the acidity of the musts by diln. and at the same time secure an EtOH strength sufficient to mask still further the defect. K. shows both by his own work and that of others that this assumption is false, the procedure to a great extent tending to defeat its purpose. The greater part of the acid of musts is destroyed during fermentation, particularly in the second stage, by a process of degradation (cf. C. A. 8, 347). This process is retarded by a high EtOH content and also by a high initial content of acid. In the light of this knowledge the rational way to correct defective wines is by removal of part of the acid by CaCO_3 treatment and by producing conditions of secondary fermentation favorable to the acid degradation process. Treatment with CaCO_3 in no way injures the quality of the product but the process must be conducted with amts. calcd. to produce the desired effect and suitable for the particular type of wine treated. Exptl. evidence showing the advantages of this treatment over diln. with sugar soln. is given.

Wine preparation experiments in the presence of sulfur dioxide with selected yeasts. P. ZANETTINI. *Staz. sper. agrar. ital.* 47, 506-30(1914); through *Chem. Zentr.* 1915, I, 337.—The presence of SO_2 with or without selected yeasts, in the fermentation hindered the decompn. of acids. As advantages are to be considered: better keeping qualities, quicker clearing, and increase of ext. and glycerol.

L. J. GILLESPIE.

Methods of examination of potable spirits. K. v. BUCHKA. Berlin. *Z. Nahr.-Genussm.* 29, 152-5(1915); cf. C. A. 8, 1186.—A discussion and criticism of the present standards and regulations for potable spirits in Germany.

L. D. ELLIOTT.

The action of the enzyme of malt on the insoluble cell-substance of the beet. A. HERZFELD AND O. SCHREFELD. *Z. Ver. Zuckerind.* 65, 135-8(1915).—In fermenting sugar beets for alc. in the same way that potatoes are handled, a strong foaming occurs that is not easily controlled. K. Windisch (*Z. Spiritusind.* 37, No. 52) claimed that the addition of malt during the cook partly removes the difficulty, due to liquefaction of the beet structure. H. and S. question the liquefying action of diastase. Samples of beet pulp were fermented with and without malt ext. On 10 g. samples the av. dry substance left in the pulp after fermentation was 8.15 g. when cooked with malt, and 8.075 g. without malt, showing that the malt has no liquefying effect.

W. L. BADGER.

A new method of yeast production from sugar and mineral salts. A. MARBACH. *Oesterr. Chem. Ztg.* 18, 62-3(1915).—The Fermentologic Institute in Berlin has discovered a method of converting inorganic N into organic N in the form of yeast protein. M. claims that this in reality is an Austrian discovery. $(\text{NH}_4)_2\text{SO}_4$ served as the N source in place of malt extract.

ARTHUR LEDERER.

Measurement of yeast fermentation by means of the liquid interferometer. OTTOMAR WOLFF. Univ. Jena. *Chem. Ztg.* 39, 197-8(1915).—The instrument was calibrated on 10% sugar (by wt.) and 10% alc. (by vol.) solns. with the 0.5 cm. cell and found to be correct. The work with yeasts on the sugar soln. was in a 1 cm. cell. Com. dry yeasts were used and the H_2O content ignored except in the white beer yeast, which was received as a paste and sucked as dry as possible. Ten g. were suspended in 200 cc. distd. H_2O and 10 cc. (equal to 0.5 g. yeast) added to 100 cc. 10% sugar soln., half of which was heated to 60° to sterilize. The other half was fermented at 28.5°, samples taken at regular intervals, heated to sterilize, and compared with the original sterilized soln. The interferometer readings for top-ferment yeast, bottom-ferment yeast and white beer yeast, resp., after 1 hr. were 67, 67, 19 divisions; after 2 hrs. 90, 80, 30; 3 hrs. 129, 125, 57; 4 hrs. 203, 177, 120; 5 hrs. 295, 235, 178; 6 hrs. 365, 280,

224. The plotted results show the rate of fermentation to be uniform after 3 hrs. and the lines practically straight. Irregularities at the start may be due to exptl. errors or to differences in rates. The 3 yeasts were kept in closed flasks 3 days and the tests repeated under the same conditions except that 10 cc. of a 10% yeast suspension was used; the results this time for top-ferment, bottom-ferment and white beer yeasts, resp., were: after 1 hr. 25, 50, 138 divisions; after 2 hrs. 103, 100, 229; 3.5 hrs. 246, 204, 350; 4 hrs. 275, 230, 397; 5 hrs. 370, 297, 475; 6 hrs. 442, 353, 550. Only the white beer yeast remained practically unchanged, but the plotted results give nearly straight lines. Results are also given on 4 com. samples of unknown origin, 2 samples being tested frequently to show the irregularities during the first 3 hrs. W. concludes that the rate may be accurately measured after the first 3 hrs., and that after further improvement the method will be of wide application. J. H. MOORE.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Action of molds on the amount of alkaloid in opium. OSCAR VON FRIEDRICH. *Z. physiol. Chem.* 93, 276-82 (1914).—*Penicillium viridicatum* and *Citromyces glaber* do not attack the opium alkaloids. *Aspergillus niger* attacks narcotine and codeine, but not morphine. *A. ostianus*, which is found on Levant opium, apparently destroys morphine slightly, as well as narcotine and codeine. E. J. C.

Evaluation of opium tinctures. P. BOHRISCH AND F. KUERSCHNER. *Apoth. Ztg.* 30, 213-4, 219-20, 226-7, 232-4 (1915).—A discussion is given of the prevailing pharm. methods with suggestions for their betterment. W. O. E.

Surface tension and testing of medicaments. P. W. DANCKWORTT. Univ. Breslau. *Arch. Pharm.* 252, 502-13 (1914).—Exts. of digitalis, cinchona, valerian, soap bark and senega were prepd. and the resulting solns. (as also one of pure saponin) tested according to Traube's stalagmometric method (cf. C. A. 4, 1765; 5, 2047, 2495, 2867), as the result of which it is believed that measurement of the drop number in combination with the action on both color solns. may be advantageously employed in drug testing. In the case of digitalis, the observed variations in surface tension appear to be due to the presence of substances other than those in which toxicity is inherent. W. O. E.

Investigation of official copaiba balsam. ERNST DEUSSEN. Univ. Leipzig. *Arch. Pharm.* 252, 590-600 (1914).—Turner's color test as prescribed in the Ger. Pharm. fails in the majority of cases, giving results only in the coarsest kind of sophistication. The procedure employed by D. is as follows: Det. the solubility of the sample in CHCl₃, abs. alc. and petroleum ether, and ascertain the d. and non-volatile residue at 100°. The most important factor in the whole investigation being the sepn. of vol.

oil, subject 30–100 g. balsam to steam distn. until practically all the oil has been driven over. For the distn. of 40 g. balsam about 5 hrs. are required. Det. the optical rotation in a 100 mm. tube; the limits for α are -2.5 and -14° . Balsams whose oils have a higher levorotatory power are suspicious, while oils showing more or less rotation toward the right are sure indicators of adulteration. The values found for d_{15} in the past are 0.900–0.905; those for α and d . are the results obtained with freshly distd. oils. In many cases a detn. of α for the volatile oil will suffice in the evaluation of the balsam. In certain instances, Turner's test as modified by Deussen-Eger may be advantageously applied and, in the event of an uncertain outcome, the volatile oil should be fractionated in vacuum and the test be made not only on the several fractions but also on the residue. In applying Turner's test, use the volatile oil, not the balsam. Test each sample twice and note that in both cases both the tone and intensity of color are the same. Should a cherry-red (violet) color develop in the course of 5 min., the presence of gurjan balsam is reasonably certain. Should the color fail to appear, take 2 drops of oil and to the AcOH soln. add 2–3 drops of freshly prepd. 1% NaNO₂ soln. In detg. the non-volatile residue, use a flat-bottomed crystg. dish of 7–12 cm. diam. D. gives the results obtained with 12 samples from the retail trade.

W. O. E.

Strophanthus oil. H. MATTHES AND L. RATH. Univ. Jena. *Arch. Pharm.* 252, 683–92 (1914).—Both the crude and the steam-treated product occurred as a greenish salve-like mass having a narcotic odor. The consts. of the crude oil were: d_{15} 0.8995, solidification pt. $11.5-12^\circ$, n_D^{40} 1.4569, acid no. 13.64, I no. 83.55; of the purified oil: d_{15} 0.9252, solidification pt. $16-7^\circ$, n_D^{40} 1.4615, acid no. 17.61, sapon no. 189.99, ester no. 172.38, I no. 94.97, R.-M. no. 1.31, Polenske no. 0.59, Hehner no. 93.9. The oil gave the elaidin reaction, was optically inactive and consisted of 73% unsatd. and 21% satd. fatty acids. The solid acids consisted of palmitic 70% and stearic 30%; arachinic acid could not be detected. The liquid fatty acids consisted of oleic 80% and linoleic 20%. The unsaponifiable portion (1.37%) contained 60% cryst. constituents, among which phytosterol and sitosterol (m. 137° , acetate m. $127-8^\circ$) were identified.

W. O. E.

The value of the digitonin method for sterols in strophanthus oil. H. MATTHES AND L. RATH. Univ. Jena. *Arch. Pharm.* 252, 694–9 (1914).—From the fact that phytosterols occur largely as esters in vegetable oils, a preliminary saponification becomes practically indispensable now that isolation of the sterols is almost always for the purpose of detg. the amt. of vegetable in animal fats. In practice, this method is tedious and hence of questionable value. Equally unsuited are the methods of Marcussen and Schelling, Fritsche, as also the more recent one of Kuehn and Wewerinke as modified by Klostermann, for the reason that on account of its cost too little digitonin is applied to effect complete pptn., which to be quant. requires more than 3 times the amt. of digitonin. The old method of extg. the soap with Et₂O gives the same yield as the dearer digitonin procedure. *Phytosterol diglonide*, C₂₈H₄₄O₁₀, crystd. from dil. MeOH, decompd. 245° without melting, is converted into the acetates of its 2 components on heating with Ac₂O in a tube at 125° . Liebermann-Burchard reaction gives rose-violet-blue. Chugaev reaction gives yellow-red with green fluorescence. Udranski reaction gives red greenish yellow-brown.

W. O. E.

Separation of dihydroxy- and tetrahydroxystearic acids. HERMANN MATTHES AND LUDWIG RATH. Univ. Jena. *Arch. Pharm.* 252, 699–703 (1914).—On oxidizing 20 g. fatty acids from strophanthus oil with KMnO₄ according to Hazura's method, 18.5 g. oxidized product was obtained after elimination of the non-oxidized portion with benzene in a Soxhlet app. This mixt. treated 24 hrs. with 100 times the quantity of cold Et₂O yielded 5 g. and, on second treatment with Et₂O, 0.5 g. The residue was

not uniform as shown by the m. p. (135–60°). A quant. sepn. was effected by extg. the acid mixt. in a Soxhlet with Et_2O , whereby 80% dihydroxystearic acid and 20% tetrahydroxystearic acid resulted, thereby showing fair agreement with the Br method. The presence of hexahydroxystearic acid could not be detected. W. O. E.

Unsaponifiable constituents of strophanthus oil. A. HEIDUSCHKA AND R. WALLENREUTER. Univ. Munich. *Arch. Pharm.* 252, 704–8(1914).—The heavy, dark green and bitter-tasting oil yielded the const.: Completely sol. in benzene, CHCl_3 , partially so in Et_2O , petroleum ether, CS_2 , and alc.; d_{15}^4 0.915, sapon. no. 178.6, R.-M. no. 3.8, Polenske no. 0.5, Hehner no. 90.2, acid no. 42.3, acidity 75.42, I no. after 3 hrs. 88.13, 18 hrs. 91.95, Br heating no. 11.1. The unsaponifiable portion amounted to 1.12%. The digitonin method gave 0.504% phytosterol, $\text{C}_{27}\text{H}_{46}\text{O} + \frac{1}{2}\text{H}_2\text{O}$, m. 140°, acetate m. 130°, propionate m. 111°, identical with sitosterol. The *diglignide*, $\text{C}_{28}\text{H}_{46}\text{O}_2$, crystals softening about 195°, m. about 212°. Salkowski-Hesse reaction with CHCl_3 light red, H_2SO_4 yellowish red with green fluorescence; Liebermann-Burchard reaction: dark green. No appreciable amt. of paraffin could be detected in the unsaponifiable portion. W. O. E.

New method of extracting lemon oil. ANON. *Chem. Eng.* 21, 166(1915).—The lemons are mashed in a large receptacle and an acid, the nature of which is a secret, is added. This causes the oil to sep. and rise to the surface, from which it is withdrawn. Subsequent treatment of the acid mixt. with a chemical permits recovery of the acid. The residual juice, pulp, peel and foreign matter are disposed of to citrate manufacturers. About 2.5% more oil is saved by this process than by the old hand procedure, the cost of extn. being only 2.3 cts. per 1000 lemons and the time involved, 22 min., may eventually be reduced to 12 min. on further perfection and under com. operation. W. O. E.

Thymol, its melting and solidifying point. ROBERT MELDRUM. *Chem. News* 111, 193–5(1915).—The m. p. detd. by the thermometer bulb method was 48.7–49.2°; by opacity method, 50–50.1°; by floating on H_2O method, 42–3°. In the latter case it is clear that H_2O lowers the m. p., due doubtless to hydration. The solidifying p. of thymol varies between 48.2 and 49.2°, the variations being due to bore of tube and absorption of moisture. The higher figure is to be accepted since it approaches more closely the m. p. W. O. E.

Menthol, its melting and solidifying point. ROBERT MELDRUM. *Chem. News* 111, 229–31(1915).—Menthol solidifies below its normal solidifying point, due to assuming the colloidal condition previous to crystn. The solidifying point varies with the colloidal condition. Its m. p. is const. at 42° but the solidifying point varies 3.3° when detd. by good methods. W. O. E.

Bulgarian rose oil. P. SIEDLER. *Pharm. Ztg.* 60, 179–80(1915).—A sample of authentic oil of rose (harvest 1914), was examd. and the resulting const. compared with those obtained (given in parenthesis) with a sample of *Ol. geranii turticum*, a common adulterant of rose oil. The oil in question was clear and yellowish in color and began to deposit crystals at 22°. d_{20}^{25} 0.857 (0.893), d_{24} 0.8565 (0.8925), d_{28} 0.856 (0.8925), d_{32} 0.855 (0.892), d_{37} 0.8545 (0.891), d_{41} 0.853 (0.8901), d_{45} 0.852 (0.8901), d_{49} 0.850 (0.8901); acid. no. 2.93 (1.13); sapon. no. 9.99 (20.64); ester no. 7.06 (17.71); I no. 169.06 (215.01); n_D^{18} 80 (42), n_D^{20} 78 (41), n_D^{28} 75 (36), n_D^{30} 74 (34), n_D^{32} 73 (33), n_D^{35} 70 (32), n_D^{40} 68 (28). W. O. E.

The therapeutic application of synthetic camphor. A. HEFFTER. *Vierteljschr. Med. oeffentl. Sanitaetsw.* 49, 5 pp. No tangible reason appears to exist why synthetic camphor should not be employed in the prep. of spiritus camphorae. Inner medica-

tion of synthetic camphor, however, must be regarded unfavorably until clinical experience has shown its beneficial utility. W. O. E.

Is wild digitalis preferable to the cultivated? J. W. HAMNER. *Pharm. Zentralhalle* 56, 165-7(1915); see C. A. 9, 510. C. O. EWING.

Wheat flour as a skin application and its substitutes. P. G. UNNA. *Pharm. Zentralhalle* 56, 183-7(1915).—In the prep. of dusting powders and ointments, U. recommends that wheat flour be replaced wherever possible by kieselguhr, CaCO_3 , MgCO_3 , kaolin, or talcum. Typical formulas are given. C. O. EWING.

The estimation of free acid and of oxychloride solution. G. ROMIJN. 'S Hertogenbosch, Holland. *Am. J. Pharm.* 87, 245-8(1915).—R. found that the test of the U. S. P. could not be employed to det. the acidity of FeCl_3 soln. when applied to a soln. containing free HCl , since the liberated $\text{H}_2\text{S}_2\text{O}_8$ decomposes in the hot soln. into free S , SO_2 and H_2O . At ordinary temp. the conversion of ferric thiosulfate into ferrous tetrathionate proceeds very slowly; this reaction is very much accelerated by the addition of a few drops of a CuCl_2 soln. The soln. decolorizes almost instantly, and becomes turbid in a very short time. The free acid may be approx. detd. by titration (Me orange indicator). The estn. is not exact, as the deposition of ferro-ferric hydroxide begins early in the operation, covering the change of color and deflecting a portion of the base from the titration. This fault may be largely overcome by adding a starch soln. as protecting colloid. The titration is effected as follows: To the cooled soln. of 0.5 g. CuCl_2 starch (1 g. CuCl_2 mixed with 49 g. sol. starch previously dried at 100°), in 50 cc. H_2O , add 2 cc. of the FeCl_3 soln. to be tested. Normal $\text{Na}_2\text{S}_2\text{O}_3$ soln. is added, 5.3 cc. for the U. S. P. FeCl_3 soln. and 9 cc. for that of the Netherlands Pharm. IV. The decolorized liquid is colored fairly strongly with Me orange soln. If the reaction of the mixt. is acid, it is titrated drop by drop with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. If the liquid is alk., it is rejected and the operation repeated after adding 1 cc. or as much as may be required, of 0.1 N HCl before adding the other reagents. W. G. GAESSLER.

The rapid determination of small quantities of heroine. REGINALD MILLER. *Am. J. Pharm.* 87, 248-50(1915).—In the absence of morphine or other interfering substances, a weighed amt. of the powder representing from $1/100$ to $1/20$ grain of heroine is placed in a Nessler tube, 1 cc. of 1% soln. of H_2SO_4 added, and then 3 cc. of a soln. consisting of 600 cc. com. H_2SO_4 , 300 cc. H_2O and 25 cc. 40% HCHO soln. This reagent produces a coloration varying from a yellowish straw for $1/100$ grain to a deep cherry-red for $1/20$ grain of heroine, depending upon the length of time the reaction is allowed to proceed and the amt. of heroine present. A series of standard tubes is prepared at the same time as the sample and the reaction is allowed to proceed for 10 or 15 min., when the color comparison is made. In case of a mixt. of cocaine and heroine, the substance is extd. in the regular manner by immiscible solvents, the residue of heroine and cocaine is weighed, and dissolved in a known amt. of 1% H_2SO_4 so that 1 cc. of the soln. will contain between $1/100$ and $1/20$ grain of heroine. One cc. of this soln. is put into a Nessler tube and treated as described above. The standard tube containing the same intensity of color is used as the basis for computing the amt. of heroine in the weighed residue, and the difference between the heroine and wt. of residue obtained by the immiscible solvent represents the cocaine. W. G. GAESSLER.

Studies of some compounds of cinchona alkaloids, certain metals and phosphoric acid. EDWIN D. WATKINS. Univ. Tenn. *Biochem. Bull.* 4, 94-5(1915).—A compd. was made by dissolving Ag phosphate in sirupy H_3PO_4 and adding quinine until no more was taken up. All attempts to obtain crystals met with failure but 2 complex crystals were found in a flask containing a concd. soln. which had stood in the dark for 15 months. It was possible to demonstrate the presence of Ag, quinine and H_3PO_4 in the dark yellow

crystal. The soln. is useful clinically in the treatment of gonorrhea. Solns. have also been prepared of Cu and Zn phosphates with quinine, quinidine, cinchonine and cinchonidine, but no crystals of these compds., if such they be, have been obtained.

A. P. LOTHROP.

Studies in synthetic drug analysis. III. Estimation of caffeine and antipyrine in admixture. W. O. EMERY AND S. PALKIN. *J. Ind. Eng. Chem.* 7, 519-21(1915).—Transfer 0.25 g. of the caffeine antipyrine mixt. to a 150 cc. separatory funnel by means of two 5 cc. portions of alc.-free CHCl_3 , followed by 10 cc. H_2O , add 1 g. NaHCO_3 and 10-15 cc. 0.2 *N* I in successive small portions, shaking vigorously. A decided excess of I should be apparent. Discharge the uncombined I by means of a small crystal of $\text{Na}_2\text{S}_2\text{O}_8$, add 15 cc. CHCl_3 and shake vigorously 1 min. After clearing, draw off the solvent into a second separator containing 5 cc. H_2O , shake and after clearing pass the CHCl_3 through a small, dry filter into a tared 50 cc. beaker and evap. to apparent dryness on the steam bath. Repeat the extrn. with two 25 cc. portions CHCl_3 , using the same procedure. Dry the nearly cryst. residue of caffeine and iodoantipyrine $1\frac{1}{2}$ hr. at 105° , cool and weigh. This is weight "A." Dissolve this weighed residue in 5 cc. glacial AcOH , add 10 cc. satd. aq. soln. of SO_2 and transfer with hot H_2O to 400-500 cc. beaker, making the final vol. about 200 cc. Add AgNO_3 soln. (about 0.3 g. AgNO_3), following with a few drops HNO_3 and heat nearly to boiling with stirring. Add 15 cc. concd. HNO_3 , cover the beaker and boil gently 5-6 min. The AgI is then detd. The wt. of $\text{AgI} \times 0.8012$ = amt. antipyrine. The amt. of caffeine is detd. by subtracting the product obtained by multiplying the wt. of AgI by the factor 1.3374 from the wt. of the composite residue "A."

ISADOR MILLER.

Characteristic reactions of chrysophanic acid and chrysarobin. LEGER. *Boll. chim. farm.* 53, 71(1914).—If a trace of chrysophanic acid is treated in a porcelain dish with 1 cc. concd. H_2SO_4 a pronounced strawberry-red color is produced. Chrysarobin yields a yellowish orange coloration under the same conditions. When triturated with alc. and treated in a test tube with 20 cc. distd. H_2O to which 5 drops NaOH soln. (35°Bé.) have been added, chrysophanic acid dissolves immediately and gives a strawberry-red coloration. Chrysarobin dissolves only slowly under the same conditions and yields a pale rose color; the red coloration becomes perceptible only after a longer time.

H. S. PAINE.

Stable tincture of iodine free from hydriodic acid. G. GAGLIO. *Boll. chim. farm.* 53, 72(1914).—Tincture of I which has been prepd. a few days contains HI which renders the prepn. irritating. HI may be destroyed and its formation prevented by adding 1% cryst. HIO_3 to tincture of I, H_2O and I being formed by the reaction. Since HIO_3 is only slightly sol. in alc., the excess HIO_3 which is added assures the destruction of HI as the latter is formed. The excess HIO_3 in the tincture is not objectionable in view of the fact that it is antiseptic and is not caustic. The presence of HI in tincture of I may be readily demonstrated by diluting a small amt. (1 cc.) of tincture of I with H_2O (5-10 cc.), filtering from the abundant ppt. of I and adding HIO_3 to the filtrate which consists of a clear, yellow satd. aq. soln. of I containing HI; a ppt. of I corresponding in amt. to the amt. of HI originally present is thus formed.

H. S. PAINE.

Stable sulfite solutions. R. NAMIAS. *Boll. chim. farm.* 53, 140(1914).—The stability of a 5% Na_2SO_3 soln. may be considerably increased by adding 4% of mannitol. The stability of sulfite solns. is also increased in lesser degree by the addition of glycerol and isobutyl alc.

H. S. PAINE.

Solubility of benzaldehyde in cherry laurel water. ASTRUC AND JUILLET. *Giorn. farm. chim.* 64, 169-70(1915).—The authors have verified the assertion that

laurel cherry water dissolves PhCHO in a proportion which increases with the amt. of HCN present. Seven-tenths cc. pure PhCHO was added to each of 3 samples consisting of 50 cc. each of an aq. soln. of 0.9828, 1.944 and 2.4516 g. HCN resp. per l. After a period of contact of 24 hrs. with occasional shaking the undissolved aldehyde was sepd. and the dissolved aldehyde was detd. according to Herissey-Denigès by means of phenylhydrazine acetate with addition of NaHSO_4 . The av. wts. of hydrazone obtained from 10 cc. of the solns. were 0.122, 0.132 and 0.135 g., resp., indicating that the solubility of PhCHO increases slightly with the proportion of HCN present. H. S. PAINE.

Secretogen. AMERICAN MEDICAL ASSOCIATION. Report of the Council on Pharmacy and Chemistry. *J. Am. Med. Assoc.* 64, 1518-9(1915).—The report calls attention to the unfounded and extravagant claims made for "Secretogen Elixir" and "Secretogen Tablets." No evidence has been presented that the absence of secretin is a cause of gastrointestinal disorders, or that secretin in any form is physiologically active when taken by the mouth. L. W. RIGGS.

Iodine and vaccination. L. B. SCOTT. *Ind. Med. Gazette* March, 1915; *J. Am. Med. Assoc.* 64, 1797-8.—Expts. in the use of I as a preliminary disinfectant of the skin in vaccination, were carried out in the ordinary course of preparing calf vaccine. Twelve out of 59 calves were selected at random and prepd. with I instead of the usual method of cleansing the skin, and vaccinated with others under the same conditions. The av. yield of lymph of the iodine calves was 7.7 g. and of the others 26.6 g. Two iodine calves developed so few vesicles that no useful material could be removed. The other 10 yielded from 2.0 to 25.5 g. Of the 47 controls, one yielded none and the others from 9.5 to 62.8 g. The difference lay in the number of vesicles which developed and not in their size or quality. L. W. RIGGS.

Official magnesium citrate. E. LÉGER. *J. pharm. chim.* 11, 157-66(1915).—The directions of the French Codex for the prepn. of this compd. from citric acid 100 g., Mg hydrocarbonate 60 g., distd. H_2O 30 g., are ambiguous. L. employs the same amts., except H_2O 35 g. Add the cold H_2O soln. of the acid to the Mg hydrocarbonate, stir the pasty mass, divide into lumps of walnut size, allow to dry on glass in an oven at 45-50° for 2-3 hrs. Pulverize, expose to air for 2-3 days, then keep in dry bottles. This prepn. is sol. in twice its wt. of warm H_2O , as required by Codex, and shows very little effervescence. When the soln. is left for 6-12 hrs. it congeals, forming a crystal mass of the compn. $\text{Mg}_3(\text{C}_2\text{H}_4\text{OH}(\text{CO}_2)_3)_2 \cdot 13\text{H}_2\text{O}$, not 14 H_2O (Heldt). 11 H_2O are expelled at 110°, the last 2 at 150°. The official compd. is no doubt a mixt. of amorphous Mg₃ salt with amts. of Mg hydrocarbonate + citric acid equiv. to it. This is indicated by its % of H_2O and of MgO, also by the viscous pptn. by EtOH of the soln. of the cold-prepared salt (Ed. Robiquet) in H_2O . The ppt. becomes cryst. after several hrs. and is then no longer readily sol. in cold H_2O . The formula 4 H_2O in the Codex for Mg citrate should be changed to 13 H_2O . 1 g. of the salt should leave upon ignition 0.16-0.17 g. of MgO. To test the solubility of Mg citrate, the temp. of 70° is proposed instead of the vague term "warm H_2O ." S. WALDBOTT.

Herbicides with arsenical base. H. DUBIEF. *J. pharm. chim.* 11, 174-80(1915).—Five com. samples were examd., 4 contained 33-58% As_2O_3 , one consisted mostly of NaOH (94.8%). Sand swept together from 1 sq. m. of treated area, yielded over 2 g. As_2O_3 . The sale of these As-compds. used for tennis fields should be prohibited. Less harmful compds. suggested are: NaOH, FeSO_4 and H_2SO_4 , formol, Na_2CO_3 , cresyl, gas liquor. S. WALDBOTT.

New researches on surgical threads. A. ASTRUC. *J. pharm. chim.* 11, 213-8 (1915).—Results of expts. are recorded, giving the breaking stress and elastic limit for various diameters of linen threads with or without knots. The results are compared

with previous ones on catguts, silk and horsehair. Diameters of various ligature threads are also given. Standards along the lines indicated should be set up by the Codex.

S. WALDBOTT.

Assay of granules of arsenious acid and of sodium arsenate. M. FRANÇOIS AND E. LASAUSSE. *J. pharm. chim.* 11, 226-37(1915).—Detn. of As in granules of the French Codex is difficult when starch is added as excipient, because As_2S_3 cannot then be filtered. In this case, det. As in $KHCO_3$ soln. of As_2O_3 by titration with I soln. This involves no previous destruction of organic matter. The method is unreliable because small grains of As_2O_3 dissolve with great difficulty. A better method is to destroy organic matter by concd. HNO_3 and to convert As into $NH_4MgAsO_4 \cdot \frac{1}{2}H_2O$. This is weighed as such after drying the salt with 6 H_2O at 100° for 10 hrs. The salt is formed by direct pptn., not through the Mo compd. because the As-molybdate is not as completely pptd. by heat as the similar P compd. The As in granules of Na arsenate, $Na_2HASO_4 \cdot 7H_2O$ is detd. by the same method, except that about twice as many granules are used, owing to their smaller % of As.

S. WALDBOTT.

Liquid extract of kava. HAROLD DEANE. *Pharm. J.* 94, 622(1915).—The Brit. Pharm. directs percolating the drug with 90% EtOH, exhausting with 45% EtOH, evapg. the latter percolate to a soft ext., and dissolving this in the reserved 90% percolate. D. points out that the 45% ext. cannot be sol. in the 90% percolate.

Brit., 1,667, Jan. 21, 1914. C. F. BOEHRINGER & SOEHNE. Bismethylamino-tetraaminoarsenobenzene solns., probably containing a carbonate of the base, are prepd. by dissolving the compd. in aq. solns. of bicarbonates. The salts of the base may also be dissolved in solns. of carbonates, or the base may be suspended in H_2O , alkali added, and the liquid satd. with CO_2 . The solns. are suitable for intramuscular injection. Alc. and acetone ppt. the compd. from its soln. (cf. C. A. 8, 2035).

Brit., 1,837, Jan. 23, 1914. FARBW. v. M. L. & B. Medicinal compounds are prepd. by treating a salt of an organic base with an aurohydrocyanic acid or a salt thereof. Suitable bases are 1-Ph-2,3-dimethyl-4-amino-5-pyrazolone and its alkyl derivs. Cf. 17,693, 1913, (C. A. 9, 356).

Brit., 1,869, Jan. 23, 1914. FARBW. v. M. L. & B. Compounds for treating tuberculosis and syphilis are prepd. by treating an organic base or a salt thereof with aurothiosulfuric acid or a salt thereof. In an example, ethylenediamine hydrochloride is treated with Na aurothiosulfate. Reference is made to 17,693, 1913 (C. A. 9, 356), and 1,837, 1914 (*supra*).

Brit., 2,090, Jan. 26, 1914. FARBW. v. M. L. & B. Arsenazo compounds are obtained by reducing the corresponding azo dyes containing an arsonic or arsenoxide group by means of hypophosphorous acid. According to examples, the azo dyes from 3-diazo-4-hydroxy-phenyl-1-arsonic acid and phloroglucinol, *m*-diazophenylarsonic acid and 2-naphthylamine-3,6-disulfonic acid, and from diazotized atoxyl and 1,8,3,6-aminonaphtholdisulfonic acid, are reduced. The products have therapeutic properties.

Brit., 2,314, Jan. 28, 1914. FARBW. v. M. L. & B. Organomercuric compounds are prepd. by treating aromatic arsenoxides or the corresponding halogen compds. containing the group, As(HC)₂ with HgO or Hg salts, arsenic being thereby replaced by Hg. In examples, the prepn. is described of compds. from 4-aminophenylarsenoxide, 3-amino-4-hydroxyphenylarsenoxide, 3-acetyl-amino-4-hydroxyphenylarsenoxide, and the hydrochloride of phenylglycine arsenious chloride. The 3-acetyl-amino compd. described is also obtainable by acetylation of the corresponding 3-amino compd.

Brit., 2,610, Jan. 31, 1914. FARBW. v. M. L. & B. Tubercle bacilli are cultivated successively on nutrient media containing increasing proportions of a Au salt, such as the cyanide, thereby obtaining bacilli resistant to the action of Au salts and containing finely subdivided metallic Au. Therapeutic preparations such as tuberculin and emulsions of the bacilli in glycerol H₂O are prepd. from bacilli so cultivated.

Brit., 2,787, Feb. 3, 1914. H. S. WELLCOME and F. L. PYMAN. In mfg. phenylseleninic and selenonic acid derivatives, phenylseleninic acid or its nitrate is nitrated, and the nitrophenylseleninic acid resulting is reduced by means of bisulfite, whereby nitrophenyldiselenide is obtained. On reduction of this compd. with Na₂S, aminophenyldiselenide results, and this, by acetylation and subsequent oxidation by HNO₃, yields acetaminophenylseleninic acid. By oxidizing the last mentioned compd. with permanganate, acetaminoselenonic acid may be prepd., and on hydrolysis, aminophenylselenonic acid is obtained. This acid and its salts are useful in therapeutics. Salts of the above-mentioned acids may be prepd. according to the usual methods of salt formation.

Brit., 3,034, Feb. 5, 1914. C. R. LIDGEY. Use of fluorides as constituents of dentifrices. Preferably the fluorides of the alk. earths or NH₄ are employed; but mineral fluorides may be used if desired. One recipe for a paste is described as follows: CaF₂ 1500 g., KClO₃ 100 g., Ca₃(PO₄)₂ 1,000 g., NaF 50 g., NH₄F 50 g., glycerol 1,000 g., menthol 15 g., oil of cinnamon 15 g., and essence of peppermint 15 g.

Ger., 280,972, June 15, 1913. C. MANNICH. Mfg. alkoxymethyl ethers of morphine by the double decomp. of the alkali compds. of morphine with halomethyl alkyl ethers of the general formula HICH₂OR.

Ger., 280,974, Dec. 19, 1913. J. D. RIEDEL, AKT.-GES. Mfg. water-soluble chondroitin-sulfuric acid salts by dialyzing concd. solns. of equiv. amts. of the alkali salt and a heavy metal against H₂O, and sepg. from the resulting solns. the heavy metal salts of the acid by evapg. with moderate heating, or by pptg. with organic solvents, such as ether or alc., to get the solid product.

Ger., 281,009, Apr. 24, 1913. CHEM. FABRIK VON HEYDEN AKT.-GES. Mfg. mercurized aminoarylsulfonic acids by heating Hg aminoarylsulfonate, or mixts. of aminoarylsulfonic acids with substances which form the Hg salt, until the resulting Hg compd. has become sol. in alkali.

Ger., 281,099, May 8, 1914. KNOLL & Co. Mfg. pure, almost odorless *m*-hydroxyphenyl acetate by acetylizing resorcinol in the known manner and treating the resulting crude product with slightly superheated steam *in vacuo*.

Ger., 281,101, July 17, 1913. Addition to 268,220 (C. A. 8, 2034). FARBW. v. M. L. & B. In mfg. heavy metal addition compounds of aromatic arsenic compounds, aromatic compds. containing trivalent As may be employed other than the As compds. specified in 268,221 (C. A. 8, 2034), 270,253, 270,256, 270,257, 270,259 (C. A. 8, 2222), 275,216 (C. A. 9, 514), and in the principal patent.

Ger., 281,390, Sept. 24, 1912. T. SARTORIUS. Mfg. tasteless quinine salts, and the like by fusing the ordinary products with gelatin or the like to form an intermediate product not sensitive to resin and balsam solns., pulverizing this, treating the powder with resin and balsam solns., and finally drying it. *E. g.*, quinine-HCl is pulverized and warmed with pure gelatin, with suitable addition of H₂O, until complete soln. of the hydrochloride is effected. After cooling, a hard, stiff mass of quinine gelatin is obtained, which can be pulverized to any desired degree of fineness. The grains of suitable size are immersed for a short time in an alc.-ether soln. of tolu balsam, whereby the grains are coated with a fine layer of this resin. The prepn. is then spread out upon a large surface, whereupon it is ready for use. The tolu-balsam coating restrains the action of the saliva until the product is in the stomach, where it dissolves in short time, and liberates the medicinal prepn.

Ger., 281,538, Jan. 26, 1913. FARBW. v. M. L. & B. Mfg. an active specific for tuberculosis. Au salts are known to have a strong bactericidal and inhibiting action on the tubercle bacillus. Opposed to this is the observation that by gradual growth of the tubercle bacillus on auriferous substrata this organism loses its sensitiveness to Au salts. Considerable amts. of finely divided Au are taken up, during such cultivation, into the protoplasm of the organism, and in this manner tubercle bacillus prepn. can be made which have an increased therapeutic activity. *E. g.*, tubercle bacilli are cultivated on 1 bouillon which, besides the usual constituents, contains an addition of AuCN in the proportion of 1:10,000,000, and then the bacilli are transferred, after growth, to fresh media which contain AuCN in the proportion of 1:5,000,000. This process is carried on, by steps, to cultures in which the AuCN is present in the proportion of 1:10,000. Such cultures, in the mass, are killed or ground in a ball mill, worked up with glycerol H₂O to a fine emulsion, and used for the prepn. of tuberculin.

Review of innovations in the inorganic chemical industry. v. HÖRLEBING. *Oesterr. Chem. Ztg.* 18, 27-9, 36-7, 44-6(1915); cf. C. A. 9, 514.—A discussion of patented processes pertaining to H, O, Os, Cl, S and N. ARTHUR LEBERER.

The potash problem and the utilization of the mother liquors of brines. ANGELO COPPADORO. Padova. *Ann. chim. applicata* 3, 225-35(1915).—The brines are generally air evapd. in summer to 35° Bé. to give ordinary sea-salt; then the mother liquors are run off into basins, and exposed to the winter cold, during which time MgSO_4 with a little MgCl_2 and some NaCl and Na_2SO_4 are deposited. C. suggests continuing the evapn. of the mother liquors during the summer following, up to 37° Bé, when $\text{K}_2\text{SO}_4 + \text{MgSO}_4$ will ppt. out, thus removing 50% of the K from the mother liquor. $\text{K}_2\text{SO}_4 + \text{MgSO}_4$ can be used as the double sulfate in agriculture. Continued treatment will remove the residue of K as $\text{MgCl}_2 \cdot \text{KCl}$ (carnallite). The final liquor may serve for extrn. of Br.

S. LEVY.

The manufacture of artificial hair. M. SCHALL. *Kunststoffe* 4, 361-3, 374-6 (1914).—A review and discussion of the patent literature. (Cf. C. A. 9, 128.)

F. W. SMITHER.

Application of spectrography to industrial chemistry (LEWIS) 7.

JOHNSTON, S. J.: *The Rare Earth Industry*. London: C. Lockwood.

U. S., reissue 13,924, June 8. L. E. SAUNDERS. Making barium oxide. See original patent 1,112,721, C. A. 8, 3841.

U. S., 1,141,136, June 1. W. J. MOELLER. Waterproofing asbestos mill-board and rendering it tough and hard, by satg. the sheet with heated candle-tar or stearin pitch, compressing to remove the excess tar and to compact the fibers and allowing the material to season by oxidation.

U. S., 1,141,265, June 1. F. RASCHIG. Continuous process of fractional distillation of petroleum, tar or other liquids. See Brit., 14,230, 1913 (C. A. 9, 147).

U. S., 1,141,371, June 1. G. VIRNEBURG. Abrasive sheet paper or cloth is coated with glue and sharp sand and the coating and backing fabric are impregnated with a mixt. formed of benzine, resin, PbO , Ni oxide and beeswax to render the sheet more durable.

U. S., 1,141,446, June 1. J. A. DECEW. Mixture for adding to ice in icing refrigerator-cars, etc., formed of crude NaCl 95% mixed with 5% of Na silicate, NaOH or Na_2CO_3 . The latter prevents corrosive action on metals by pptg. any hygroscopic Ca or Mg salts in the NaCl .

U. S., 1,141,482, June 1. S. R. OFFENHEIM. Charring dried kelp for recovery of potash and other values. A direct flame is applied to the top of a thick layer of kelp in the charring furnace, to ignite it, and after a considerable portion of the kelp near the flame is in a glowing condition the igniting flame is discontinued and a down draft maintained through the kelp until the whole layer is charred. The temp. of the furnace walls is maintained below 350° and care is taken not to incinerate the mass.

U. S., 1,141,639, June 1. J. H. HIRT. Making soda ash by granulating hot Na_2S by mixing it with wet sawdust, then adding an excess of raw limestone to the mixt. and heating to about red heat.

U. S., 1,141,920, June 8. E. O. BARSTOW. Making lead arsenate by adding PbO to a soln., containing both HCl and arsenic acid, in sufficient amt. to combine with the HCl and ppt. PbCl_2 , sepg. the ppt. and then adding an additional amt. of PbO somewhat less than required to combine with all the arsenic acid. (Cf. C. A. 8, 2784.)

U. S., 1,141,921, June 8. E. O. BARSTOW. Making bromine by reacting with Cl on a soln. of FeBr_2 and FeBr_3 of such strength that the Br is practically insol. and

seps. by gravity, sepg. the Br and agitating it with more of the FeBr_2 and FeBr_3 soln. to remove any traces of Cl.

U. S., 1,141,922, June 8. E. O. BARSTOW. **Making bromine** by reacting with H_2SO_4 on a strong soln. of bromide and bromate of K or Na (in the mol. proportions of 5:1). The Br seps. from the sulfate soln. in liquid form by gravity.

U. S., 1,141,944, June 8. E. S. DAWSON, JR. **Electrical insulation**; a mixed glycerol ester of phthalic and oleic acids mixed with castor oil; made by heating glycerol 92 with phthalic anhydride 148 parts to 200° , adding oleic acid 70.5, castor oil 70.5 and phthalic anhydride 37 parts and continuing the heating at slightly below 200° until a homogeneous product is obtained. It is a flexible, reddish, resinous material which on heating to 160° for 15 hrs. is rendered insol. and infusible. Cf. C. A. 8, 1215.

U. S., 1,141,947, June 8. F. W. DEJAHN. **Making ammonia** by passing a mixt. of H and N under a pressure of 80–90 atm. and at $520\text{--}540^\circ$ over a catalyst formed by impregnating pumice stone with $\text{Ni}(\text{NO}_3)_2$, igniting at 550° , heating in H for 8 hrs. at 550° , treating with metallic Na and heating to 450° in anhyd. NH_3 . Fe or Mo may replace Ni.

U. S., 1,141,948, June 8. F. W. DEJAHN. **Producing ammonia** by passing a mixt. of H and N under a pressure of 80–90 atm. and at $520\text{--}540^\circ$ over a catalyst formed by igniting a salt of Co, Mn, Ti, Ce, B, U or Si upon a carrier of pumice and heating the product (after reduction in H), with metallic Na and anhydrous NH_3 at 300° .

U. S., 1,141,994, June 8. C. UEBEL. **Making nitric acid**. See Fr., 461,452 (C. A. 8, 2464).

U. S., 1,141,999, June 8. C. L. WEIL. **Making salt from brine**. The brine is passed through a superheating system into a hooded evapg. pan, allowed to evap. in the pan and the size of grains of salt deposited is regulated by the application of jets of air to the surface of the brine. The hood of the evapg. pan is supplied with heated air by a blower. Cf. C. A. 8, 1857, 3222.

U. S., 1,142,068, June 8. F. S. WASHBURN. **Monoc ammonium phosphate** substantially free from diammonium phosphate is made by treating phosphate rock with H_2SO_4 to form a crude soln. of H_2PO_4 . This soln. is filtered and rendered slightly alk. with NH_3 and then slightly acidified with H_3PO_4 . Cf. C. A. 9, 129.

U. S., 1,142,371, June 8. F. C. SCHMITZ. **Making phosphoric acid**. A mixt. of phosphate rock, SiO_2 and C is heated in an elec. furnace and air is supplied to the gases thus formed, to produce P_2O_5 . The latter is sprayed with a dilute soln. of H_3PO_4 and the aq. acid collected after absorption in a checker-work tower working on the counter-current principle. Before entering the tower the gases are allowed to bubble up through the acid to remove impurities which might clog the tower.

U. S., 1,142,397, June 8. J. W. BURROUGHS. **Making phosphoric acid** by fusing together a mixt. of phosphate rock and SiO_2 and treating the gases formed with H_2O while they are at a temp. above $700\text{--}900^\circ$.

U. S., 1,142,619, June 8. G. PUM and A. GLAESSNER. **Artificial sponge** is made by mixing viscose and cotton or other fibrous material with granular NaCl (or other material which when dissolved will harden viscose) and the resulting pasty mass is formed into pieces of the desired size and treated with dil. HOAc to dissolve out the granular material and harden the viscose.

Brit., 1,766, Jan. 22, 1914. T. BOBERG, N. TESTRUP and TECHNO-CHEMICAL LABORATORIES. **Treating giant kelp** to ext. alkali salts. The treatment is similar to the treatment of peat as described in 10,834, 1903, 17,610, 1911 (C. A. 7, 411), 17,427, 1912 (C. A. 8, 416), and 24,639, 1912 (C. A. 8, 1498). The seaweed is pulped and forced

under pressure through a heater and heat recuperator, and then cooled and pressed. The temp. employed is about 170° . The expressed liquid is used for the extn. of alkali salts and I, and the residue, after further pressure and drying out by flue gases, if desired, may be used for solid fuel or distd. to form gaseous fuel, the final charred residue being suitable as a filtering or clarifying agent. In prepg. a pulp containing 6-10% by wt. of insol. solids, undue inclusion of air may be avoided by pulping in a partial vacuum or under H_2O , or by a combination of both these processes. In pulping fresh material, the expressed liquid obtained by pulping previous material, or the liquid used to wash the pulp cake, may be used. Reference is also made to 4,684, 1911 (C. A. 6, 2309), 12,462, 1911 (C. A. 6, 3039), and 24,748, 1911 (C. A. 7, 1601).

Brit., 2,841, Feb. 3, 1914. P. E. WILLIAMS. Ammonia is obtained from thiocyanates, as from a soln. of $Ca(SCN)_2$ obtained from NH_4SCN prepd. from gas as described in 23,624, 1909 (C. A. 5, 2718), by heating with an alkali or alk. earth in the presence of H_2O , and removing the COS which is also produced. The $Ca(SCN)_2$ soln. is evapd. nearly to dryness and mixed with slaked lime, and the mixt., covered with a layer of slaked lime (to absorb the COS), is heated to $500-600^{\circ}$ in an Fe vessel placed in an externally heated chamber. A vessel of H_2O may be placed in the chamber, or a jet of steam may be injected to maintain a moist atm. so as to provide H_2O for the reaction and assist in the removal of the NH_3 . The NH_3 may be directed into H_2SO_4 in a closed vessel, the upper part of which is connected with an air pump or gas exhauster.

Brit., 2,952, May 19, 1914. E. J. HUNT and W. T. GIDDEN. Zinc sulfate solution, which may be obtained by neutralizing with crude ZnO or $ZnCO_3$, the acid liquors produced in the electrolysis of $ZnSO_4$, is purified from ferrous Fe and Mn by treating with PbO_2 or Pb_2O_4 , preferably under the influence of heat. An alkali, a metallic oxide such as ZnO , or a carbonate such as $CaCO_3$ or $ZnCO_3$, may be added to complete the pptn., and the soln. may be further purified by Zn or Zn dust. Cf. C. A. 8, 3271.

Brit., 2,988, Feb. 5, 1914. INTERNATIONAL SALT CO., A. W. BROWN and J. H. WEBSTER. In a regenerative open-hearth furnace for melting and treating salt or like mineral substances, the regenerators extend under the whole furnace (which comprises a melting portion and a purifying portion), and are of special design; both portions of the furnace are connected up with the regenerators, and the purifying hearth is divided up into special baths.

Brit., 3,367, Feb. 9, 1914. H. LEVIN. A metal polish consists of a vehicle or vehicles such as gasoline, methylated spirits, oleic acid, and fat, and the ppt. (consisting of basic Fe sulfate combined with Na_2SO_4 and traces of sulfates of Cd, Cu, Cr, Ni, Zn, or Mn), obtained in the removal of Fe from solns. of the above metals by the process of 17,672, 1912 (C. A. 8, 407). Any well-known polishing material may be added such as $CaCO_3$, whiting, dolomite or hearthstone, calcined MgO , silicates of Al, pumice, Na_2CO_3 , Na_2SiO_4 , borax, and an alkali sulfate.

Brit., 3,388, Feb. 9, 1914. HENKEL ET CIE. Magnesium perborate. See Ger., 278,868 (C. A. 9, 1096).

Brit., 3,476, Feb. 10, 1914. HENKEL ET CIE. Magnesium perborate. See Ger., 278,868 (C. A. 9, 1096).

Brit., 3,477, Feb. 10, 1914. HENKEL ET CIE. Zinc perborate is obtained by m. a Zn salt such as $ZnSO_4$ with an alkali perborate. Cf. 3,388 (*supra*).

Fr., 468,349, Feb. 12, 1914. NITROGEN GHS. M. B. H. In the production of nitrogen and carbon dioxide, the sintering of the Cu and combination with CuO , incident to carrying out the process expressed by the equation— $Cu + \text{air (or combus-}$

tion gas) $\rightarrow$ $\text{CuO} + \text{N}(+\text{CO}_2)$ —at a high reaction temp. ($800-900^\circ$), is avoided by the addition of metal oxides which at first are oxidizing with loss of O and are then reducing (as alloys) and combine with the O. The temp. of the reaction is moderated thereby to 180° . Such oxides are $\text{Al}(\text{OH})_3$ and CaO , as well as SiO_2 .

Ger., 279,622, July 23, 1913. B. JIROTKA. Mfg. molded articles with smooth surfaces from wood fiber by beating the material up, in small amts., to a smooth product, and then projecting it against the form.

Ger., 280,548, July 25, 1913. A. PUCHAT. App. for mfg. gypsum articles.

Ger., 281,093, Mar. 11, 1914. J. BEHRENS. Separating vapor mixtures by bringing them into contact with mechanically adsorbent bodies, with the employment of suitable pressure. The period of contact with the wood charcoal, or other adsorbent material, is shorter than would be required for the adsorption of the whole amt. of the vapor mixt., and the temp. of adsorption is maintained above the vaporizing temp. of the liquid mixt. By such a partial adsorption the more readily adsorbed constituents of the vapor mixt. have the advantage. *E. g.*, with the aid of a current of vapor of 7% HOAc , suitably regulated, a 30% HOAc can be obtained, by driving out the adsorbed and condensed mixt. of HOAc and H_2O from the charcoal, by heating. The residual H_2O contains then but a fraction of 1% of HOAc . By raising the adsorption temp., by superheating the vapor mixt. and thereby simulating a gas mixt., the sepn. can be increased materially. In this manner, a 60-80% HOAc can be obtained from a 7% acid, while the residual H_2O contains but 2% HOAc . By too strong superheating of the vapor mixt., the effect is materially lessened, and finally is nil. An analogous property is exhibited by a mixt. of steam and HCO_2H vapor. The charcoal can be used repeatedly.

Ger., 281,169, July 23, 1913. O. HAASE. Preserving gypsum molds by treatment with a mixt. of H_2SiF_6 and ZnSiF_6 .

Ger., 281,211, Sept. 17, 1912. VEREIN CHEMISCHER FABRIKEN. Construction and operation of an app. for mfg. high percentage nitric acid (the mono-hydrate). Cf. C. A. 9, 697.

Ger., 281,255, Aug. 20, 1912. F. MENZEL. Construction and operation of a machine for cementing mica.

Ger., 281,305, Mar. 30, 1913. A. CLASSEN. Obtaining finely divided metals and alloys by reducing the metal salt solns. in the presence of gelatose, a colloid obtained by protracted boiling with H_2O of glue or gelatin. Preferably the metals or alloys or their compds., if necessary with the employment of an etching process, are comminuted and mixed with gelatose, adding indifferent substances to the mixt. The process is applicable for heavy metals which form colloids, such as Au, Ag, the various Pt metals, the earth metals, such as Ce, La, Di, Th, also W, Mo, U, Ti, and Nb. Preferably, gelatose is added to a boiling soln. of reducible metal salt solns.. The soln. can be employed directly, or may be evapd., whereby indifferent substances may be added as a vehicle for the colloid metals. *E. g.*, Pt 0.13 g. (as in the form of H_2PtCl_6), and boiling H_2O 100 g., are mixed with 2 g. gelatose and 1 drop of $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ and evapd. to the desired concn. Before or during the evapn., asbestos, sawdust, or kieselguhr may be added. According to the material, the mass is dried and ignited, or allowed merely to dry. By this process contact bodies with the peculiar colloidal properties of the coating may be readily prepd., which are more active than Pt-asbestos. When the gelatose in the contact body is incinerated by ignition, the ash forms easily. The resulting contact bodies are free from admixts. such as Na_2CO_3 , HCOOH , HCHO , and similarly acting reducing agents may be employed also.

Ger., 281,354, Sept. 21, 1913. Addition to 262,235 (C. A. 7, 3398). G. SAUER-BREY, MASCHINENFABRIK AKT.-GES. App. for the continuous decomposition and solution of potassium salts, according to the principal process.

Ger., 281,355, Mar. 21, 1914. Addition to 262,235 (C. A. 7, 3398). G. SAUER-BREY MASCHINENFABRIK AKT.-GES. In an app. for the continuous decomposition and solution of potassium salts, and the like, the app. specified in the principal patent is modified with a view to securing a more advantageous circulation of the soln. Cf. C. A. 9, 1378.

Ger., 281,501, July 2, 1907. CONSOLIDIERTE ALKALIWERKE AKT.-GES. FÜR BERGBAU UND CHEM. In obtaining potassium chloride in coarsely granular form, the hot KCl soln. flows counter to the cooling liquid, which flows through a series of cooling chambers arranged in a trough, and comes in contact with the outer surfaces of these cooling chambers. The crystals collect on the cooling surfaces and are dislodged by shock, to collect upon a transporting band which removes them.

Ger., 281,537, Feb. 10, 1914. Addition to 281,005 (C. A. 9, 1538). Z. LITTMANN. The app. described in the principal patent for the manuf. of sulfuric acid is modified in that the several tubular towers are stepped, the series being connected by pipes from the lower wider towers to a cross pipe connecting the several series through the uppermost tower in each series. A damper is provided in the cross pipe next to each of the uppermost towers.

Ger., 281,584, Jan. 4, 1914. BADISCHE ANILIN- UND SODA-FABRIK. In a process of analyzing gas mixtures, 2 containers are filled with the gas mixt. under exam. and a gas for comparison, at the same temp. (being immersed in the same water bath). The gases are then simultaneously allowed to flow out of small openings at as nearly the same pressure as possible, until a certain vol. of the one gas has been delivered, whereupon the vol. of the other gas which has flowed out in the same time is employed for the analysis.

Ger., 281,723, May 14, 1914. C. BEINDL. Mfg. hydrocyanic acid and cyanogen compounds by the catalytic union of gaseous or volatile C compds. and N compds. If pure metals are employed as the contact bodies, high yields are not obtained. Under like conditions these yields are materially greater if the contact bodies contain, besides the metal, certain admixts. such as compds. of the alkalis, alk. earths, earth metals, compds. of Mo, U, W, Os, Ti, etc., or the corresponding ores. Only small amts. of these additions are necessary to secure the desired speed of reaction.

Ger., 281,831, June 1, 1913. C. BREITHAUPT and W. ZIERVOGEL. Separating salts from solutions with the aid of a current of air. The hot soln. is led through a drum through which is directed a current of air. The soln. is taken up by the walls of the drum as it is rotated, thereby presenting a thin film of the liquid to the action of the air.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Scientific glass and glassware assured by the French manufacturers. BERLE-MONT. *Ann. fals.* 8, 54-62(1915).—A popular address before the French Soc. for the Encouragement of Home Industries. There is no doubt but that the French glass manufacturers will be able to supply all the scientific glassware needed at home.

H. S. BAILEY.

The use of Glauber's salt as a substitute for soda in bottle glass. ANON. *Glas-ind.* 26, No. 17/18(1915).—It is difficult to get good glass with this substitution even

with the addition of fluorspar. Four formulas are given. *Dark green bottle glass.* Sand, yellow 150, Glauber's salt 50, lime, crude 40, fluorspar 12; soda 7, iron oxide 3, MnO_2 9, coal 5; sand, yellow 100, Glauber's salt 26, lime 24, coal 3, iron oxide 3, MnO_2 7. *Semi-white bottle glass.* Sand, white 100, Glauber's salt 30, soda 3, lime 26, fluorspar 8, coal 3; sand, white 100, Glauber's salt 28, lime, crude 26, coal 3, MnO_2 (decolorizer) 0.01.

J. B. PATCH.

Fuel consumption. ANON. *Glasind.* 26, Nos. 9-14(1915).—Fuel consumption in glass factories is briefly discussed under the following heads: the heat value of the fuel, suitable furnace practice, the system, size and correct construction of the melting furnace, the m. p. of glass, the number of auxiliary ovens and leers, the need of careful attention to the whole system.

J. B. PATCH.

The lead question in the ceramic industries. A. BERGER. *Glasind.* 26, Nos. 3-6(1915).—Historical.

J. B. PATCH.

Majolica glazes and imitation ware of gypsum. B. *Diamant* 37, 49-50(1915).—An imitation of the English majolica glazes can be produced with the following recipe: feldspar 40, flint 32, chalk 30, white lead 27, H_3BO_3 26, SnO 15, $\text{Na}_2\text{B}_4\text{O}_7$ 5, Na_2CO_3 $1\frac{1}{4}$, and small amounts of Cr_2O_3 and UO_2 according to colors desired. The whole is finely ground together and gum tragacanth added as a binder. After applying the glaze the ware is heated in a muffle to Seger cone 1 or 2. If the glaze is applied to gypsum, first coat with linseed oil and lacquer.

J. B. PATCH.

Clay deposits near McMurray, Alberta. S. C. ELLS. Canada Dept. Mines, *Bull.* 10, 15 pp.(1915).—Clays overlying the Devonian limestone and beneath bituminous sand contain carbon derived from the sand. This carbon is a serious defect and renders the safe burning of wares made from them a difficult process. A description including burning test, absorption test and fire-shrinkage, of 25 different samples of clay is given.

R. L. SIBLEY.

The color of firebricks. ANON. *Brit. Clayworker* 24, 23(1915).—Color is no indication of the refractoriness. Harder burning which is desirable, usually harms the color.

C. H. KERR.

Sparkling plug insulators. ANON. *Brit. Clayworker* 24, 25(1915).—The requisites are: (1) must withstand sudden heating and cooling; (2) must withstand rough usage; (3) must form a gas-tight joint. Only 3 materials are widely used, porcelain, steatite and mica. Porcelain comes chiefly from Limoges, France. A typical compn. (very different from English porcelain) is china clay 40, feldspar 40, flint 10, steatite 6. French insulators are a one-fire product and are of lower coeff. of expansion than the English product.

C. H. KERR.

The thermal conductivity of refractory materials. G. DOUGILL, H. J. HODSMAN AND J. W. COBB. *J. Soc. Chem. Ind.* 34, 465-71(1915).—The infusibility required in refractories is largely dependent upon thermal cond. but the less the heat conducted away the greater is the thermal economy. Thermal cond. is of the greatest importance in all uses where heat is transferred through the refractory wall as in gas retorts, etc. A new app. for detg. thermal cond. is described. Bricks of ordinary size are tested in a gas furnace; the brick is heated on one side and the temp. of the bottom and top sides is measured; the quantity of heat transmitted through the brick is detd. by a H_2O calorimeter which is jacketed by a 2nd calorimeter at the same temp. on the "guard ring" principle. Detailed description is given. Thermal cond. is calcd. from the equation $k = [Qd/a(\Theta_2 - \Theta_1)t]$. k is thermal cond. (in C. G. S. units = cal. per sec. per 1° difference in temp. of faces of a 1 cm. cube). Q = quantity of heat transmitted in time t . a = area. $\Theta_2 - \Theta_1$ = temp. difference. d = thickness. The table shows the results obtained.

Specimen.	Temp. range.		Mean k .
	Lower surface.	Upper surface.	
Fire brick burned cone 10-11.....	825°	260°	0.0029
	970°	300°	0.0029
	1080°	330°	0.0036
	1440°	550°	0.0040
Same as above, 2nd sample.....	1100°	420°	0.0033
	1350°	510°	0.0039
Fire brick burned cone 8-9.....	1005°		0.00165
	1020°		0.00120
Fire brick silicious, many SiO ₂ grains.....	1300°	310°	0.0025
Silica brick.....	1240°	440°	0.0039
Silica brick, another specimen.....	995°	295°	0.0030
	1210°	370°	0.0035
	1395°	440°	0.0042
	380°	270°	0.0170
Magnesia brick.....	560°	325°	0.0151
	600°	400°	0.0148
	700°	450°	0.0132
	750°	470°	0.0116
	875°	525°	0.0110
	1025°	580°	0.0101
	1040°	590°	0.0098
	1370°	690°	0.0091

The above values of k have no meaning apart from the temp. limits given therewith. Equations for the true value of k for definite temps. are derived for MgO and fire-clay bricks. Thermal cond. of MgO bricks decreases with increase in temp., contrary to the behavior of fire bricks and most other refractories. At all temps. MgO is a better conductor than fire clay. Data on SiO₂ are not yet complete but they are much like fire brick (probably slightly higher). The fire brick data show clearly the necessity of hard burning for uses where rapid heat transmission is important. *Joints:* Preliminary expts. showed thermal cond. of joints to be of the order of $1/10$ that of the bricks. *Porosity:* Contrary to Mellor, the authors show that pore spaces in comm. refractories act as heat insulators under all ordinary conditions. Only at temps. far above the m. p. of refractories does the radiation through pores equal the conduction through the refractory grains. If the size of pore is of the order of 1 cm., the transmission by radiation becomes of the same magnitude as conduction across the solid. *Diffusivity:* During the heating up, before making thermal cond. detns., "diffusivity" or "thermo-metric cond." was noted. Diffusivity = k/CS , where C = sp. heat and S = sp. gr. In C. G. S. units diffusivity measures the rise in temp. produced in 1 cc. of the substance by 1 cal. flowing for one sec. through 1 sq. cm. of a layer 1 cm. thick and having a temp. difference of 1° between its faces. The following table shows the data:

Material of brick.	Thermal conductivity.	Temp.	Specific gravity.	Specific heat.	Temperature diffusivity.
Fireclay.....	0.0028	500° C.	1.95	0.23	0.0062

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Constitution determination and sintering of Portland cement clinkers. K. ENDELL. *Mitt. Deut. Port. Cement Ind.* 3, 283-4, 296-7(1914).—A review.

A. J. PHILLIPS.

Constitution of portland cement clinkers. E. JÄNECKE. *Mitt. deut. Port. Cement Ind.* 3, 309-10(1914).—A cooling-curve app. is described in which the circuit from the thermocouple contains a millivoltmeter where the temp. is read and the rate of cooling controlled. The current passes through a const. resistance of 30,000 ohms and a variable resistance to a mirror galvanometer. The latter is operated in a dark room with the light of a single-filament lamp reflected back to a registering app. which is so constructed that a piece of photographic paper moves across a slit into which is reflected the light from the mirror. The cooling curve is recorded as the paper unrolls. Lags in the cooling curves of Cu, Zn, Ag and $8\text{CaO} \cdot 2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3$ are shown. A. J. PHILLIPS.

Autoclave test. R. J. WIG AND H. A. DAVIS. U. S. Bur. of Standards. *Eng. Record* 71, 655-6(1915); cf. C. A. 7, 1594, 3005, 3006; 8, 2932; 9, 138.—Some neat cements which are sound according to the standard atmospheric steam test but unsound in high pressure steam exhibit signs of unsoundness when stored under normal

conditions in dry air. This may require 9 mos. or more to develop in neat cement specimens, whereas the strengths of mortars and concretes fail to show any difference in the cementing qualities of cements that pass and fail the high pressure steam test. There is also but small difference in linear change between cements passing and failing, whether the specimens are stored in air or H_2O . 70% of a total of 51 brands of cements tested passed the autoclave test, and those originally unsound usually became sound after aging from 2 to 6 mos. Cements normally unsound in the atmospheric or high pressure steam test will generally become sounder if the coarser particles are removed. While fineness is not essential to soundness, the coarse particles usually cause the expansive cracking and disintegrating action of unsound cements in the accelerated soundness tests. The autoclave test should be used on all cements that are to be incorporated in cement mortar or concrete products that are to be cured in steam at pressures above atmospheric. The autoclave test may forecast the behavior of neat cement or rich mortar under normal conditions in dry air but not the behavior of cement in concrete. Cements passing this test are not superior in cementing value (as detd. from compressive strengths of concrete) to cements that fail, nor do they make more permanent or durable concrete. Cements failing the standard atmospheric steam test but meeting the other specifications show in some instances normal strengths in concrete. For practical work the results of the investigation fail to show that the high-pressure steam test is of value as a means of detg. the ultimate soundness of concrete.

A. A. KLEIN.

Electric drive for economical operation and development of cement mills. J. B. PORTER. *Concrete-Cement Age* 6, C. M. S. 35-8(1915).—Curves are given showing power consumed in manuf. of cement.

A. A. KLEIN.

Shrinkage of concrete and conditions of curing. F. R. McMILLAN. Univ. Minn. *Eng. Record* 71, 489-90(1915).—Tests on concrete beams extending 13 mos. show that moisture during the early stages of curing only retards the shrinkage, the final dimensions being practically independent of early curing conditions. The concrete was of 1:2:4 mix. Compressive strength tests on cylinders showed that better curing conditions increased the strength about 50%.

A. A. KLEIN.

Temperature changes in mass concrete. C. M. PAUL AND A. B. MAYHEW. *Proc. Am. Soc. Civil Eng.* 41, 790-810(1915).—Tests ranging from 3 to 19 months on the Arrowrock Dam showed that large bodies of concrete deposited rapidly during summer developed a temp. of 90-95° within 30 days and held it for several months. Concrete 3.5 ft. from an exposed face showed no daily variation in temp. when the daily air variation was about 50°. Also in *Eng. Record*, 71, 710(1915).

A. J. PHILLIPS.

Weathering of concrete prevented by waterproofing. J. L. LYTH., U. S. Reclamation Service. *Eng. Record* 71, 486(1915).—To overcome disintegration of concrete structures due to alternate freezing and thawing of H_2O , vertical surfaces are treated with alum and soap solns. and horizontal surfaces with paraffin. The repaired structures have undergone 2 severe winters without further disintegration. Also in *Eng. Contr.* 43, 346-7(1915).

A. A. KLEIN.

Coal slack for concrete aggregate. R. B. KETCHUM. *Eng. News* 73, 540(1915).—Concrete was 1:5, 1:10 and 1:15 mix and compression tests were made at 30 and 90 days. 1:5 mix is about 50% as strong as gravel concrete at 90 days, while the leaner mixes are about 25% as strong. Coal concrete makes good gains in strength between 28 and 90 days.

A. A. KLEIN.

Use of six-inch and eight-inch aggregate in concrete work. E. O. KRATOR. *Eng. Record* 71, 556-8(1915).—Large aggregate is cheaper than smaller sizes and when machine-mixed produces a stronger concrete.

A. A. KLEIN.

Value of microscopic investigation on blast-furnace slag. H. PASSOW. *Mikroskopos* 1914-15, 243-6.—The value of blast-furnace slag as a raw material for cement manuf. depends upon its physical state. Slow cooling results in the formation of hard crystals which render the slag unfit for admixt. with cement. If the slag is cooled rapidly by means of water, air, or steam, crystn. can be almost completely prevented and the resulting slag has an entirely different chem. compn. and valuable properties from the standpoint of cement manuf. The use of the microscope makes possible the control of the cooling process at all time. Experience gained in repeated microscopical exams. may even permit one to draw fairly reliable conclusions as to the chem. compn. of different furnace slags. Photomicrographs illustrate the various points made and a complete bibliography on this subject is appended. So-called blast-furnace cement is more resistant to the action of sea water and similar salt solns. than other types of cement. C. A. NOWAK.

Domestic flint pebbles to replace foreign supply. ANON. *Concrete-Cement Age* 6, C. M. S. 38-9(1915).—As a substitute for Danish pebbles in grinding, tough flint pebbles from Tex., Miss., Ark. and Mo. are suggested. Rhyolite from the Rocky Mountain and Pacific states, quartzite, diabase from Me. and felsite and trap from the Lake Superior region may be used. Pebbles of rhyolite, basalt and other lava contribute to the cement a puzzolan material that is advantageous. A. A. KLEIN.

General practice in sand testing. E. B. VAN DE GREYN AND C. M. MONTGOMERY. *Eng. Record* 71, 551-2(1915).—Outfit and methods are discussed. A. A. KLEIN.

The economic side of sand testing. CLOYD M. CHAPMAN AND NATHAN C. JOHNSON. *Eng. Rec.* 71, 734-7(1915). F. BACHMANN.

Waterproofing of solid steel floor railroad bridges. Discussion. H. H. QUIDBY, et al. *Proc. Am. Soc. Civil Eng.* 41, 459-79(1915).—Adhesive tests of cotton duck satd. with bitumen on steel and 1:2:4 concrete specimens showed superior adhesion of bitumen to steel. A cut-back treatment with dil. HCl followed by painting with bitumen showed much improvement for concrete bitumen adhesion. Mastic as protection for waterproofing will either be too soft in summer or so hard as to crack in winter. Not less than 5 layers of felt, burlap, cloth or asbestos are used as covering materials. The best material as regards durability is felt of cotton and wool fibers (25-30% of latter). Coal tar is considered equal to, if not superior to, asphalt. A. J. PHILLIPS.

Bituminous materials for road construction. Standards for their test and use. *Surveyor* 47, 348-51, 406-8(1915).—Report of committee of Am. Soc. of Civil Engineers. W. D. C.

The methods for preserving wood. TH. WOLFF. *Kunststoffe* 5, 86-7, 98-100, 111-2(1915).—A review and discussion of the causes of decay, preservative methods, etc. F. W. SMITHER.

Tests of wood preservatives. HOWARD F. WEISS AND C. H. TEESDALE. Forest Service, U. S. Dept. Agr., *Bull.* 145, 20 pp.(1915).—An investigation to secure data on the practical value of a number of compds. and chemicals as wood preservatives. Among the points considered in connection with the materials were (1) chem. and phys. properties, (2) effect of preservative on the strength of the wood treated with it, (3) the ability of the preservative to penetrate and diffuse through the wood, (4) the permanency of the preservative after its injection into wood, (5) the combustibility of wood treated with the preservatives, (6) the toxic efficiency of the preservative in preventing the growth of wood-destroying fungi, (7) the corrosive action of the preservative on steel, (8) the effect of the preservative on paints applied to the wood subsequent to treatment. Air-seasoned hemlock was used in the tests. B. E. BROWN.

Preservative treatment for wooden silos. GRO. M. HUNT. *Wood Preserving* 2, 23(1915).—Pine is the most easily treated; hemlock, tamarack, spruce and Douglas fir are treated with difficulty. The cheapest and simplest treatment is by the brush method. Distillate creosote is heated to 180° and applied by brush or old broom by flooding creosote over surface, 2 coats being applied. For a silo containing 3000 board feet, the cost of creosoting will be about \$12.00.

C. N. WILEY.

The Galesburg tie plant. ANON. *Wood Preserving* 2, 19-20(1915).—Description of a modern railroad timber preserving plant. It has a capacity of 1,500,000 ties.

Brit., 2,244, Jan. 28, 1914. J. A. CALANTAR. Forming road surfaces (1) by spraying or painting the road with a binding agent such as tar, pitch, asphalt, or bitumen mixed with oil and scattering or sifting over it, while wet, absorbent fibrous material; or (2) by casting upon the road granules or nuts made by dividing while hot, as by rolling and cutting, a known compn. consisting of a binding agent mixed with fibrous material and a portion of oil. Suitable fibrous substances are sawdust, crushed bark, coconut fiber or coir, and as suitable oils there are mentioned creosote and linseed oils.

Brit., 2,661, Feb. 2, 1914. G. M. PARK. In an app. for cooling clinkers in the manufacture of portland cement and for like cooling purposes, the material from a kiln falls into a hopper and passes down a shoot into a rotary chamber containing H_2O or fitted with a H_2O spray. The material is lifted out of the H_2O as the chamber rotates by radial plates and screens, and falls into a 2nd shoot leading to a drum fitted with angle-pieces to cascade the material. After leaving the drum the material traverses in succession a series of concentric open-sided trays provided with suitable peripheral openings, and is finally discharged on to a conveyor. The shoots form a passage for conducting the escaping steam to a stack in which it is condensed by a H_2O spray and led back to the rotary chamber. The trays are supported by radial arms on a projecting shaft driven by gearing, the other end of the cooler being supported by a bearing-ring. The openings between the rotary chamber and the drum facilitate the escape of steam. The free lime in the material is hydrated in the rotary chamber, and the $Ca(OH)_2$ and surplus H_2O pass over a flange into a trough. The rotary chamber with the shoots and stack may be fitted at the front end of an ordinary cooler.

Ger., 281,387, Dec. 14, 1913. CHEM. FABRIKEN DR. KURT ALBERT and DR. L. BEREND. Mfg. compns. for preserving, impregnating, and coating wood. The tar oils used heretofore for these purposes possess very little or no viscosity, and are not suited, therefore, for holding color powder, *i. e.*, to serve as a vehicle. In this process, the color powder and the tar oil are combined with suitable emulsifying agents in such manner that the color powder is distributed, with the oil, in small particles, in the emulsifying agent, with the aid of vigorous stirring. The color powder is thereby so finely divided that upon diln. with H_2O it appears to be completely emulsified, and that it penetrates the wood deeply, with the oils, while the colors obtained by working up the pigments with the ready prepd. emulsion do not possess this property. Preferably, resins are dissolved first in the tar oils, and these resin solns. are employed as emulsifying agents. However, the tar oils can be thickened directly by resinifying with aldehydes the phenols contained in tar oils. In this manner a greater viscosity of the oil is secured, and consequently a greater adhesion on and in the wood, also increased bactericidal power of the tar oil, increased permanency as to atm., chem., and mechanical conditions, and finally a more rapid and complete breaking down of the emulsions. As emulsifying agents are specified casein, albumins, and the like. Mineral or artificial

colors may be employed. Additions may be made to increase the poisonous properties of the product.

J. W. Thomas. JOHN GREENAWAY. *J. Chem. Soc.* 107, 588-9(1915).—An obituary. L. G. C.

The source of energy of machines. M. BODENSTEIN. *Z. angew. Chem.* 28, 1, 209-13(1915).—B. reviews the sources of energy available at the present time. He calls attention to the fact that the heat converted to useful work in the most efficient steam engine or internal-combustion engine is only 16% and 33%, resp., of the heat input, and in order to conserve the present supplies of fuel other methods of conversion of heat to work are necessary. It is proposed to convert heat energy directly to elec. energy or make use of the radiant energy from the sun by means of photochem. reactions for the production of elec. or other form of energy. Both of the proposed methods, although possible on a very small scale in the lab., are not practical from a com. standpoint.

H. R. GUNDLACH.

Preparation of charcoal for small warming stoves. H. FREUND. *Pharm. Zentral-halle* 56, 171-4(1915).—Wood charcoal is powdered, mixed with about 3% KClO_3 or some other suitable oxidizing agent, a binding material such as tragacanth or gelatin is added, and the mixt. is pressed into small perforated cylinders. When ignited these cylinders burn slowly without odor and with a steady glow. The little warming ovens for which they are designed are much used by troops in the field but will be of use for invalids also.

C. O. EWING.

A study of boiler losses. A. P. KRATZ. Univ. Ill. Eng. Expt. Sta., *Bull.* 78 (1915).—A series of 25 tests was made on a 500 h. p. boiler with the heat balance so subdivided as to isolate and det. the amts. of the losses chargeable to boiler, furnace, and setting. A comparison of fresh screenings with coal that had been weathered for 6 years showed that although the latter had deteriorated in heat value, when burned with heavier drafts and in thinner fuel beds, it maintained a boiler capacity and efficiency equal to that obtained with the fresh coal.

Waste heat from combustion motors; its recovery and use. ERNST GOLZ. *Chem. App.* 2, 92-5, 113-6(1915).—Calcns. of the available heat from Diesel engines with 16 cuts of app. for heating H_2O , buildings, and the Sulzer app. for drying chemicals. Cf. C. A. 9, 1106, 1261.

J. H. MOORE.

Exhaust steam for making water gas. S. A. REINHARD AND G. A. SCHNERR. *J. Gas Lighting* 130, 404-6(1915).—Wet exhaust steam causes no end of trouble from entrained moisture and is hardly more economical than live steam. Marked improvement can be obtained by superheating the exhaust, raising the temp. to about 450°F . by tar burners and maintaining pressure between 2 and 2.5 lbs. by an auxiliary live steam valve. Tests show the steam used per 1000 cu. ft. of gas made can be reduced 25-35%, or approx. the whole of the live steam necessary for gas making is saved. In addition, fewer boilers and less labor are required, and the furnace works much more efficiently with the dry steam.

B. W. GRIMES.

By-products of the gas industry. W. J. A. BUTTERFIELD. *Chem. Trade J.* 56, 395(1915).—The by-products from the coke and gas industry of the United Kingdom are compared with those of Germany.

C. A. COLE.

Gas generators producing fluid slags. K. VOIGT. *Feuerungstechnik* 3, 153-4 (1915); cf. C. A. 9, 165.—The development of this type of generator and the results obtained are reviewed. The advantages of the slagging generator over the non-slagging type are pointed out. The loss of heat through the formation of the slag is not a disadvantage, since in the non-slagging type combustible matter is carried off in the clinker or ashes.

H. R. GUNDLACH.

Centrifugal dehydration of water-gas tar at Amsterdam. ANON. *Am. Gas Light J.* 102, 349(1915).—At ordinary temp. the difference in sp. gr. of water and tar is insufficient to allow their sepn. The higher the temp., however, the wider is the difference between the sp. gr. of the two liquids, and centrifugal sepn. is possible. The centrifugal app. has a drum revolving on a vertical shaft with a flat ring, 4 in. wide at the upper parts of the interior, fitted in such a way that a small space is left between the inner surface of the drum and the outer circumference of the ring. When by the speed of revolution the tar and water are sepd., the tar travels upward along the inner surface of the drum, through the free space of the ring where it makes its exit through the tar offtake. The water forms a layer at the side of the tar and, traveling upwards, its passage is barred by the flat ring where there is an outlet for it. The tar is preheated in a rectangular tank with a cover of sheet iron. The temp. for perfect dehydration of tar lies between 60° and 70°. The heated tar often has a water content of about 60% but one operation in the centrifugal machine delivers tar with less than 1% water. Water-gas tar emulsion containing 30-90% water is treated in the same app. at 90-100°.

P. J. COLE.

Future of the natural gas industry. J. C. McDOWELL. *Gas Age* 35, 537-40 (1915).—The supply and its conservation are treated.

B. W. GRIMES.

Gas compressor and washer combined. ANON. *Gas Age* 35, 562(1915).—The pump consists of a casing and a head, surrounding a wheel with projecting blades, which is rigidly mounted on a shaft supported by bearings. The casing is elliptical in section; the periphery of the rotor is a true circle. Water or other liquid is carried by the revolution through the pump through ports cut above and below the narrow part of the ellipse, drawing gas by its alternate recession and surging, and delivering steadily without pulsation.

B. W. GRIMES.

Formaldehyde process for estimating ammonia. ANON. *Gas World* 62, No. 1606 (Coking and By-product Section), 11(1915).—HCHO combines with NH_4 salts to form hexamethylenetetramine. The acid of the NH_4 salts thus set free is titrated with alkali. The HCHO soln. (20%) must be made neutral to phenolph. with 0.1 N KOH. For *weak liquors* pipet 17 cc. into a beaker, add methyl orange and titrate to neutrality with 0.1 N HCl, boil a few minutes, cool, add 40 cc. water and 10 cc. HCHO soln., titrate with 0.1 N KOH. For *strong liquors* make up 17 cc. to 100 cc. with H_2O , titrate 10 cc. of this soln. with 0.1 N HCl, using methyl orange, boil, cool, add 40 cc. H_2O and 30 cc. HCHO, titrate. For $(\text{NH}_4)_2\text{SO}_4$ dissolve 1.7 g. in 100 cc. H_2O . In a 10 cc. portion, neutralize the free acid with 0.1 N KOH (methyl orange), add 30-40 cc. HCHO and titrate (phenolph.).

M. L. TROWBRIDGE.

Gas economy in iron works. K. RUMMEL. *Z. Ver. deut. Ing.* 58, 1216-21(1915).—A continuation of article by R. (cf. C. A. 9, 142) regarding the economic use of gas in iron works and the comparison of efficiencies with other fuels. The use of gas for regenerative furnaces and furnaces used intermittently is discussed. R. concludes

that for heavy rolling mills the gas is most efficient when burned under boilers for the production of steam power, instead of being used in gas engines for power production.

H. R. GUNDLACH.

Physical constants of gas oils and derived tars. W. F. RITTMAN AND G. EGLOFF. *J. Ind. Eng. Chem.* 7, 481-4(1915).—Results are given on fractional distn., sp. gr., viscosity, surface tension and refractive index of 4 gas oils and derived tars. The differences between the constituents of an aliphatic oil and its derived tar are shown by the differences between volatility-gravity, volatility-refractive index, and volatility-surface tension relations. That aromatic hydrocarbons can be formed from the aliphatic hydrocarbons occurring in petroleum has been verified.

ISADOR MILLER.

Composition of peat tar. E. BORNSTEIN AND F. BORNSTEIN. *J. Gas Lighting* 129, 731(1915).—In the distn. of peat to utilize the heat and to ext. the N there is produced a tar, described as follows: H_2O , 48.5%; distillate 150-70°, 1.8; 170-220°, 4.7; 230-70°, 10.7; 270-330°, 24.7%; residue (coke), 9.4; gas and loss, 0.2%. The combined distillates yielded: Phenols 18, alkaloids 1, oils 34, pitch (paraffin) 47%. It is suggested that the paraffin, vaseline oils and phenols could be profitably extd. from the peat tar.

Brit., 1,676, Jan. 21, 1914. T. RIGBY and WETCARBONIZING LTD. Peat which has been subjected to heat treatment such as described in 10,834, 1903, 17,610, 1911 (C. A. 7, 411) and 25,146, 1912 (C. A. 8, 1498), to render its H_2O more freely expressible, is further subjected to a distn., the gases resulting from which are treated for the recovery of by-products such as wax, HOAc, MeOH and NH_3 ; the residue, after cooling, if necessary, is gasified, and the resulting producer gases are treated separately from the distn. gases for the recovery of by-products. The distn. is effected in continuous or intermittent retorts, preferably heated internally by steam or H or the hot producer gases obtained by the gasification of the residue. The distn. gases after sepn. of the by-products may be burned alone or mixed with the producer gases; or if the MeOH and similar materials can be neglected, the distn. gases, after sepn. of waxes and HOAc, may be returned to the retorts and continuously circulated with a const. rejection of a certain proportion. Combustion products from furnaces, where such are used for heating the retorts or gases or for raising steam, may be utilized to assist in drying the peat as described in 17,610, 1911, and 24,748, 1911 (C. A. 7, 1601). Part only of the residue from the distn. may be gasified, the remainder being utilized otherwise as fuel. Reference is also made to 17,427, 1912, 9,392, 1913, and 11,133, 1913 (C. A. 8, 416, 3359 and 3499, resp.).

Brit., 2,054, Jan. 26, 1914. BERLIN-ANHALTISCHE MASCHINENBAU AKT.-GES. A combustible gas, consisting mainly of H, is obtained by passing oil vapor through a bed of incandescent fuel.

Brit., 2,069, Jan. 26, 1914. L. L. SUMMERS. Coking. See U. S., 1,114,045 (C. A. 8, 3852).

Brit., 2,609, Jan. 31, 1914. A. HOLLIS. In a scrubber for producer gas, etc., of the kind in which the gas passes downward through woody filtering material, such as wood-wool, sawdust, and chips, carried on perforated shelves, drippings of tarry matter and moisture from the top shelves are prevented from fouling the material on the lower shelves by the provision of 1 or more sheet-Fe trays, having openings covered by hoods for the passage of the gas. The tray is preferably inclined towards a gutter formed on the inside face of 1 of the walls of the filter and leading to a drain pipe.

Brit., 2,649, Feb. 2, 1914. Q. MOORE and DOWSON & MASON GAS PLANT CO. A dry-bottom gas producer of the kind described in 28,054, 1908, with provision for discharge of ashes. Cf. C. A. 9, 1386.

Brit., 2,650, Feb. 2, 1914. Q. MOORE and DOWSON & MASON GAS PLANT CO. Process and app. for the recovery of tar and ammonia liquor from producer or other gas. The gas is led through condensers to a tar extractor placed at such a level that the tar and liquor flow back to the condensers. The gas, after or during the extn. of the NH_3 in an acid bath at this stage, then passes to further condensers the tar and liquor from which pass back to the first mentioned condensers wherein they flow in the reverse direction to the gas. The tar and liquor pass to a separator from which the liquor is led through a cooler and thence to scrubbers through which the gas is passed after it leaves the last of the second pair of condensers. Means are provided for cutting the tar extractor out of the circuit when required. The H_2O used in the cooler and thereby heated may be supplied to the H_2O jacket of a producer.

Brit., 3,363, Feb. 9, 1914. H. W. WOODALL. In heating coke ovens, gas-retorts, etc., the oven or retort gas of high calorific value is dild. with waste products of combustion, in order that it may be used in the producer-gas burners, and also to prevent deposition of C and local overheating.

Substitutes for benzene in explosion motors. Velocity of gasifying. II. D. MENEGHINI. Padova. *Ann. chim. applicata* 3, 235-44(1915).—For pure liquids the velocity of evapn. is independent of the pressure, is proportional to the product of the vapor tension of the liquid by the internal friction of the gaseous current, and varies, for a given temp., as the product of the vapor tension by the mol. wt. of the substance evapg. The app. employed for the evapn. tests consisted of a U-tube contg. the liquid, connected on one side with a long CaCl_2 tube for drying the entering air, and on the other side with a capillary that was connected at the same time with a H_2O -manometer and a H_2O -aspirating pump. The aspiration was regulated to 40 mm. of H_2O in the manometer, under which condition 3 l. of gas, during the 5 min. period employed in each test, passed through the app. The U-tube was immersed in a thermostat at 25° (the external temp. varied from 17 to 20°), and for each expt. 10 cc. of the liquid tested were used. The difference in wt. of the U-tube gave the amt. of liquid evapd. Alc. of 99, 95, 90, 80%, resp., gave 1.99, 1.90, 1.85, 1.85% of evapn. CH_3OH gave 3.60%. (This is an exception to the general rule mentioned above and referring to the product of the vapor tension and mol. wt.; it is higher than the figure obtained from calcn.). $\text{C}_6\text{H}_7\text{OH}$ gave 0.85%, benzene 5.10%, toluene 1.73%. Alc.-benzene mixts. contg. by vol. 10, 20, 30, 50, 70, 80, 90%, resp., of benzene gave 3.80, 4.95, 5.90, 6.20, 6.30, 6.25, 6.20%. For alc.-toluene mixts. contg. 10, 25, 50, 60, 75, 90%, resp., of alc., the figures were 2.90, 3.15, 3.10, 2.95, 2.65, 2.25%; benzene-toluene mixts. with 15, 30, 50, 70, 90% benzene 2.50, 3.40, 4.30, 4.80, 5.05%. Addition of toluene to alc.-benzene mixts., amtg. to 10% of the vol. of the benzene, did not appreciably influence the velocity of evapn. Values obtained from com. benzene, toluene, and alc., were practically the same as those given by the pure products. A com. benzine of d. 0.700, as ordinarily used in explosion motors, gave a value of 20.50%. Values for velocity of evapn. at 0° were also detd. for the above-mentioned substances. V at $0^\circ/V$ at 25° varied from 0.221 to 0.308. S. LEVY.

The theory of the perfect sheet asphalt surface. C. RICHARDSON. *J. Ind. Eng. Chem.* 7, 463-5(1915).—Colloid chemistry is of great value in interpreting the behavior of asphalt surfaces and as a guide to their rational construction. The importance of the colloid phase depends on the very great surface it affords, which increases the surface energy and also the extent of the adhering film of bituminous binder.

ISADOR MILLER.

Natural and artificial asphalt. J. MARCUSSEN. *Kunststoffe* 5, 75-8, 90-2, 101-2 (1915); cf. C. A. 9, 146.—A general discussion under captions: properties, uses, coal

tar and coal-tar pitch, oil gas tar and water gas tar, brown coal pitch, petroleum residues, residues from fatty distns. (candle tar, stearin pitch, palm oil pitch, etc., used in the manuf. of roofing papers). Analytical methods and tests in general use are given in some detail. Tables and cuts are given.

Brit., 1,878, Jan. 23, 1914. J. J. SHEDLOCK and OPTIME MOTOR SPIRIT SYNDICATE. In the manuf. of motor spirit from hydrocarbon oils, the oils, after purification, are emulsified with H₂O by means of resin soap or other emulsifying agent, and the emulsion is heated in the presence of Fe or steel shavings or Ni or other catalyst. In order to remove S, pitch, etc., the oil is forced, under a pressure of 3-6 atms., over caustic alkali, lime, metal oxides, etc., contained in a vessel which is heated to 300-400° F. The oil then passes through a settling vessel and is delivered partly into a mixing tank, in which the emulsion is formed. The emulsion is mixed with the remainder of the oil in another vessel. The resulting mixt. or emulsion, still under pressure, is sprayed into a cracking chamber, which is heated to 500-900° F. The products from the cracking chamber are delivered through restricted passages into an expansion chamber, in which vaporization occurs, and from which the vapors and gases are led to a scrubber. The motor spirit is then sepd. in a condenser, the remaining gases being delivered by an exhauster to a gas-holder and used as fuel in the burners for heating the heating and cracking chambers. The heavy oils collecting in the expansion chamber and scrubber may be returned for further cracking or may be fractionated. The heating and cracking chambers are provided with internal and external flues. Oil, H₂O, or emulsion may be injected into the cracking chamber through apertures in order to regulate the temp.; H₂O or steam may be admitted to the heating chamber through a pipe.

Brit., 2,142, Jan. 27, 1914. J. B. ERWIN and O. R. ERWIN. *Extinguishing fires in oil tanks*. See U. S., 1,085,875 (C. A. 8, 1202).

Brit., 2,948, Feb. 4, 1914. W. A. HALL. *A motor spirit is obtained by cracking a heavy hydrocarbon oil under such conditions that as much as possible of the gaseous product consists of unsatd. hydrocarbons, mixing alc. vapor with the gases, and condensing under pressure. In an example, gas oil or fuel oil is passed through a coil heated to approx. 600° and at such a rate that only about 25% is converted into gas*

and superheating is avoided; the gas is freed from considerable oil at a temp. above the b. p. of alc. and passed rapidly through alc. The resulting mixt. of gas and vapor is led to the compressor. Alc. may be denatured in this manner. Cf. C. A. 9, 1840.

Brit., 3,422, Feb. 10, 1914. G. E. THOMAS and G. L. EVANS. Purifying used lubricant, such as hot-neck grease, by passing it over a magnetic separator.

Ger., 278,956, Sept. 20, 1913. ZELLER & GMELIN. Mfg. a highly viscous lubricating agent, using as initial material the so-called petroleum hard pitch, which is a solid at ordinary temp., brittle, and m. 80-100° according to Krämer-Sarnow. This hard pitch remains, from the distn. of the crude oil to produce lubricating oil, and cylinder oil, as a waste product heretofore useless. This hard pitch is extd. with a volatile solvent such as C_6H_6 , $CHCl_3$, benzine, petroleum, gasoline, or the like, and the extn. is purified with H_2SO_4 and lye, whereupon the solvent is driven out from the ext., washed with H_2O , and recovered. A cylinder oil, liquid at room temp., is obtained; it has a viscosity of about 20° Engler at 100°, and serves, with a flash-point of 310-315°, as a good lubricant for high-pressure steam engines. The residual material from the 1st extn., after fusion, forms a hard pitch, sol. in the known solvents for mineral oil pitch, with lustrous fracture and a m. p. about 50° higher than that of the initial material. It may be employed as an insulating material, as asphalt binder, in roof paper manuf., for street paving, and also in the varnish industry.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Explosives. H. LE CHATELIER. *Rev. metal.* 12, 37-79(1915).—A review.

L. T. FAIRHALL.

Picric acid; its manufacture and liability to explode. T. OSBORNE. *Chem. Eng.* 21, 158-9(1915).—Risk when wet is slight. Grinding dry crystals is subject to danger from foreign bodies which strike fire and form "dust" explosions. The max. quantity allowed in one risk is 2000 pounds. Theoretically, picric acid cannot be exploded unconfined but it has apparently done so in certain accidental explosions.

EDWARD J. KELLEY.

Notes on dye-reactions. GUSTAV ULRICH. *Z. ges. Textil-Ind.* 1914, No. 22; *Chem. Zentr.* 1915, I, 275-6.—The new naphthol A S red dyes may be distinguished from the older β -naphthol reds by their reaction with concd. H_2SO_4 . Cotton dyed with the latter turns blue-violet to blue when treated with the acid, while the soln. becomes fuchsin red. No color changes take place in the case of the newer dyes.

H. L. OLIN.

Turkey red oils. W. FAHRION. *Seifensabr.* 35, 365-7, 391-2, 415-7(1915).—A discussion is given of various contradictions in the literature of this subject, together with some analyses. F. has concluded that the active constituents of turkey-red oil are probably not the sulfonated fatty acids but esters of hydroxy acids, and in the case of red oil derived from castor, the poly ricinic acids. By boiling turkey-red oil $1\frac{1}{2}$ hr. with dil. HCl, all of the organically combined S is split off. By sapon. with alc. KOH only a portion of the organically combined S is removed, the remainder may be taken out by boiling with HCl.

E. SCHERUBEL.

Failures in bleaching. A. KRAMER. *Seifensieder-Ztg.* 42, 308(1915).—Spots which are often found on fibers after bleaching are due to oxycellulose which absorbs bleaching chemicals in different proportions from regular fiber. It may be tested for as follows: Dissolve dry indanthrene yellow in concd. H_2SO_4 , pour into H_2O and neutralize, mix a small amt. of this soln. with 8% NaOH and introduce the fiber. If oxycellulose is present the fibers turn blue after rinsing and drying. Pure cellulose does not show this reaction.

E. SCHERUBEL.

Prevention of decomposition of peroxide bleaching baths. V. WINTSCH. *Rev. mens. blanchissage* 7, 102(1914); *J. Soc. Chem. Ind.* 34, 349.—Alk. solns. of H_2O_2 and other bleaching agents containing active O, are rendered stable by the addition of B compds. and pyrophosphates. A liter of soln. containing 34 g. H_2O_2 , 1.7 g. NaOH, 30 g. $Na_2P_2O_7$, and 5 g. $NaBO_2$, had not diminished in available O content after heating to 60° for 1 hr. After keeping at this temp. 3.5 hrs., a diminution of 84% was noted in the case of a sample which did not contain the metaborate, whereas the sample above mentioned lost only 11.2% of its available O. These additions are also useful for the preservation of neutral or acid bleaching baths.

Ger., 280,646, July 15, 1913. AKT.-GES. FÜR ANILIN-FABRIKATION. Mfg. water-soluble greenish blue dyes of the anthraquinone series by heating 1-amino-4-halogenanthraquinone-2-sulfonic acids with aromatic amines, H₂O, and Cu or Cu compds. in the presence or absence of acid-binding agents.

Ger., 280,647, Aug. 29, 1913. Addition to 275,537. BADISCHE. Mfg. vat dyes by treating the nitro- or amino-derivs. of dibenzanthrone or isodibenzanthrone with halogens or substances yielding halogen.

Ger., 280,649, Nov. 22, 1913. GES. FÜR CHEM. IND. IN BASEL. Mfg. new vat dyes by treating indigo or indigoid dyes, in the presence of concd. H₂SO₄, with oxidizing agents.

Ger., 280,711, Sept. 12, 1913. CASSELLA & Co. Mfg. a blue-green vat dye by heating 1-aminoanthraquinone and *o*-chlorobenzaldehyde to a high temp., with the addition of an acid-binding agent and a small amt. of Cu or similar metal salt, with or without a diluent.

Ger., 280,712, July 10, 1913. CASSELLA. Mfg. acridone-like condensation products of the anthraquinone series by condensing β -naphthoquinone-3-carboxylic acid with aminoanthraquinones with free *o*-position with respect to the amino group, and treating the resulting compds. further with dehydrating condensation agents.

Ger., 280,787, Mar. 26, 1913. L. KALB. Mfg. vat dyes by treating 1,1'-dinaphthyl-8,8'- or -2,2'-dicarboxylic acid or their derivs., such as the esters, chlorides,

nitriles, as well as the nucleus substitution products of these compds., with acid condensing agents, such as H_2SO_4 , or AlCl_3 , and the like.

Ger., 280,840, June 25, 1913. Addition to 268,505 (C. A. 8, 2067). **BAYER & Co.** Mfg. vat dyes of the anthracene series by treating the indazoles obtained from *o*-diazomethylantraquinones instead of with halogens or agents yielding halogens, with other condensing agents.

Ger., 280,880, Oct. 21, 1913. **BADISCHE.** Mfg. vat dyes by treating with halogens, or halogenating agents, the dyes obtained according to 276,956 (C. A. 9, 966), addition to 276,357 (C. A. 8, 3243).

Ger., 280,881, Aug. 1, 1913. **BADISCHE.** Mfg. vat dyes of the anthraquinone series by condensing the halogenfluorenonecarboxylic acids with amines of the anthraquinone series.

Ger., 280,882, and addition 280,883 Aug. 12, 1913. **BADISCHE.** Mfg. anthraquinone derivatives. See Brit., 21,027, 1913 (C. A. 8, 3240).

Ger., 280,975, Mar. 14, 1913. **FARBW. v. M. L. & B.** Mfg. ether-like condensation products of the anthraquinone series by condensing alizarin or its substitution products with ethylene halides in the presence of halogen-hydride-binding agents, with or without the addition of catalyzers, such as Cu or its compds.

Ger., 281,046, Oct. 28, 1913. **R. STOLLÉ.** Mfg. *N*-substituted isatins.

Ger., 281,048, June 24, 1913. **BAYER & Co.** Mfg. sulfonic acids of aromatic aminothiazoles by heating dehydrothiotoluidine, its homologs or substitution products or the corresponding primulines, with H_2SO_4 to high temps.

Ger., 281,050, Oct. 14, 1913. Addition to 276,808 (C. A. 9, 966). **FARBW. v. M. L. & B.** Mfg. oxidation products of the indigo series by oxidizing indigo, its homologs or substitution products in neutral aq. suspension, with permanganate solns.

Ger., 281,052, July 19, 1913. **FARBW. v. M. L. & B.** Mfg. isatins by treating with oxidizing agents, in aq. soln., those condensation products of *o*-nitroaldehydes which yield indigo with alkali. Cf. C. A. 9, 966.

Ger., 281,507, June 21, 1913. **L. HERMSDORF and H. TEUFER.** Mfg. silk-like cotton. See Fr., 463,073 (C. A. 8, 3373).

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Use of lead compounds in paints. **ANON.** *Chem. Trade J.* 56, 437-8(1915).—Abstract of British Departmental report which recommends prohibition of the importation, sale and use of any paint material which contains more than 5% of its dry wt. of sol. Pb. The amt. of sol. Pb is to be detd. by treating the dry matter, free from H_2O , varnish matter, etc., with 1,000 times its wt. of an aq. soln. of HCl containing 0.25% of actual HCl, filtering, pptg. Pb in filtrate with H_2S , and finally detg. Pb as PbSO_4 . Arguments by E. M. Johnson of the United Kingdom White Lead Corroders in protest against the above report, which, according to J., means the extinction of the British white lead industry, are appended.

E. W. BOUGHTON.

Recent advances in our knowledge of ultramarine. **L. BOCK.** *Z. angew. Chem.* 28, I, 147-52(1915).—An extensive discussion of the reactions that occur during the manuf. of ultramarine, the nature of the products, etc., with review of the literature and account of exptl. work. Many reactions and formulas are given. B. states that

the nature of the combination between the Al_2O_3 and the SiO_2 in ultramarine is clear, but that the manner in which the S is combined is still uncertain. In blue ultramarines which are rich in SiO_2 and S, the latter is partly attached to the alkali in the mol. and is partly in a state of low oxidation. In green ultramarine the S is combined as sulfide and disulfide.

E. W. BOUGHTON.

Paint vehicles as protective agents against corrosion. M. TOCH. *J. Ind. Eng. Chem.* 7, 510-4(1915); *J. Soc. Chem. Ind.* 34, 592-5(1915).—Results of coating steel with 52 different vehicles.

ISADOR MILLER.

Linoxyn. F. FRITZ AND CLARA ZYMANDL. Triest. *Chem. Rev. Fett-Harz-Ind.* 22, 27(1915); cf. *C. A.* 6, 305; 7, 1816; 8, 2495.—The following additional analytical table on linoxyn products is given without comments by the authors:

Product.		Sp. Gr. at ° C. (H ₂ O 4°).	I No.	% ash.	% non-oxid. acids.	% oxidized acids.	% H ₂ O-sol. acids.

P. ESCHER.

Behavior of alcoholic rosin solutions alone and while drying. O. PRAGER. *Seifensieder-Ztg.* 42, 218-9(1915).—The solubility, viscosity, clearness, color and time of drying, of 9 kinds of rosin are tabulated, also the behavior during and after drying on glass, tin, hard wood, paper, leather, split leather and stained wood. E. SCHERUBEL.

Detection of phenol-formaldehyde condensation products (STEINITZER) 7. Products resembling linoxyn (SCHARFER) 27. Linoleum substitutes (CHARDET) 30.

ANDES UND ERWIN: Lack und Firnis-Fabrik. Die Fabrikation der Lacke, Firnisse, Buchdrucker-Firnisse und des Siegellackes. 6 Aufl. Wien: A. Hartleben. 270 ss. 3.80 M.

U. S., 1,141,177, June 1. C. ELLIS. Making white lead. Molten Pb is divided into small streams which are forced together to form a spray of the molten metal and the latter is exploded by a jet of steam. The product is then treated with air, H_2O and CO_2 , with or without HOAc.

U. S., 1,142,365, June 8. G. E. POSSA. Printing ink for intaglio or photogravure processes on cylinder or rotary presses; formed of casein or albumin 1.4, borax 0.18,

sulfonated castor oil 2.8, a lake color 5.4, turpentine 3.5, carbon black 2.2 and H_2O 14 parts.

Brit., 2,318, Jan. 28, 1914. J. FRACHEBOURG. Production of colored illustrations or transparencies by superimposing by transfer monochrome prints. The monochrome prints are made in greasy inks on gelatin, collodion, celluloid or other films supported on temporary paper backings, the gelatin, etc., films being finally transferred and superimposed on a final backing. The temporary paper backings are coated with albumin, casein, dextrin, arrowroot, cellulose, gum, glue, varnish or, preferably, gelatin to close the pores and cover the fluff, and then with wax, paraffin, or stearin before being coated with the films which receive the monochrome prints. The films are transferred to their final backing in a soln. of gelatin and sugar in H_2O to which $HOAc$ may be added, the sepm. taking place between the wax and the film.

Fr., 467,464, Jan. 19, 1914. INTERNATIONAL COLOR & CHEMICAL CO., INC. In the manuf. of paints and enamel, the pigment (chrome yellow) is combined, in the presence of an excess of a pptnt. ($Pb(OAc)_2$) with soap soln (below 5% of the wt. of the pigment), and kneaded up with heating (60°), below the m. p. of the metal soap (Pb stearate), with a vehicle (linseed oil), whereby the H_2O is sepd. out. The complete dehydration follows by heating to 100° .

Ger., 281,432, Nov. 8, 1913. Addition to 270,993 (C. A. 8, 2248). M. WEN-DRINGER. Mfg. a high grade, pure and clear coumarone resin from heavy benzenes b. $160-80^\circ$, also a clear and light-fast solvent naphtha, having an agreeable odor with prevention of emulsions and sepn. of acid resins. Application of the principal patent has demonstrated that the use of H_2SO_4 of 60° Bé. can be avoided, and that a still brighter and high melting coumarone resin is obtained—and indeed without the formation of acid resins and sulfonation—if, in adding the small amts. of concd. H_2SO_4 (0.25–0.40 vol. %), care be taken that the temp. of the contents of the washer is not raised above $40-50^\circ$. If the temp. of the washer reaches $100-120^\circ$, secondary reactions, especially the formation of naphtha-insol. acid resins, are unavoidable, if the inflowing H_2SO_4 be not immediately dild. At a lower temp., however, the action of the concd. H_2SO_4 in the formation of the naphtha-sol. coumarone resin is not changed. This depression of the temp. can be effected by the insertion of cooling worms into the washer, by the passage of air, by slow feeding of acid, or otherwise. The color of the coumarone and indene resin is perfectly clear, citron- to amber-yellow, and these resins melt at a higher temp. according as less H_2SO_4 and a lower temp. are employed in the polymerization. Also, in the distn. of the polymerized naphtha, over-heating must be avoided, and therefore direct firing is not used.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Catalytic hydrogenation of fatty acids in the laboratory. H. DUBOVITZ. *Seifen-sieder-Ztg.* 42, 304–6(1915).—The app. described consists of a round-bottom flask connected with a tube containing the catalyzer deposited on pumice. The tube is connected to a receiver which in turn connects with a suction line. The fatty acids to be hardened are distd. by means of heat supplied by a Bunsen burner and pass through the catalyzer tube which is also heated. Gas is generated in a Kipp app. and is properly purified before coming into contact with the catalyzer and fatty acid vapors. E. S.

The cleavage of fats by high pressure steam. J. MARCUSSEN. *Mitt. kgl. Material-prüfungsamt* 32, 502–6(1914); through *Chem. Zentr.* 1915, I, 812.—M. reports results obtained on repeating tests perviously reported (C. A. 2, 3413; 3, 255). Tribenzoin

tripalmitin, and tristearin were used separately in one test and palm kernel fat in another. It is concluded that the hydrolysis of the fats on heating with H_2O under pressure is bimolecular with intermediary formation of mono- and di-glycerides. The same conclusion holds for the hydrolysis of fats by acids and enzymes. Cf. C. A. 1, 360, 2556.

F. W. SMITHER.

The detection of rape oil. HANS KREIS AND EMIL ROTH. Basel. *Mitt. Lebensm. Hyg.* 6, 38-40(1915).—The authors have modified their earlier method (cf. C. A. 7, 3802). Saponify 10 g. of oil by heating on the bath with 50 cc. 95% alc. and 5 cc. 40% NaOH. After driving off alc., take up the soap with H_2O , add an excess of HCl and boil gently. Wash the fatty acids 3 times with hot H_2O in a separatory funnel, wash them into a 150 cc. Erlenmeyer with 50 cc. 95% alc. and heat to boiling. Add 0.75 g. Pb acetate dissolved in 25 cc. of hot alc. and let stand 12 hrs. at a temp. above 15° . Filter the ppt., wash it 3 times with alc., return it to the flask and boil with 100 cc. 1% HCl. Cool, wash the flask contents into a separatory funnel, and shake with ether. Wash 3 times with H_2O and distil from a tared flask. A rape oil residue should weigh 1.3 g. Fractionate a second time and det. m. p. of acid. Values below 50° indicate the presence of rape oil.

H. L. OLIN.

Products resembling linoxyn obtained when steam-distilling vegetable oils. W. SCHAEFFER. Triest. *Chem. Rev. Fett-Hars-Ind.* 22, 37-8(1915).—An analysis is given of a dark colored sticky oil which had accumulated in the oil separator of a superheated steam deodorizer for vegetable oils: oxidized fatty acids 44.56, non-oxidized fatty acids 29.49, H_2O -sol. non-volatile acids 6.12, insol. residue 0.43, ash (much Fe) 5.25%.

P. ESCHER.

American neutral oil soap. E. SCHUCK. *Seifensieder-Ztg.* 42, 323-4(1915).—Description of the crutcher in which this kind of soap (for textile purposes) is made. The fat basis is generally corn, cottonseed or linseed oil, but 20 to 25% of rosin may be added. S. gives the following formula: corn oil 550 lbs., 24.5° Bé. KOH 594 lbs., M rosin 110 lbs., H_2O 800 lbs. Fatty acids may be used in place of the oil, but the KOH must be increased to 653 lbs. per batch.

E. SCHERUBEL.

Purification of low grade fats. P. T. *Seifensieder-Ztg.* 42, 371-2(1915).—A discussion of old and well known methods.

E. SCHERUBEL.

Talc and its use in soap and cosmetics during war time. F. *Seifensieder-Ztg.* 42, 324-5, 346-7(1915).

E. SCHERUBEL.

Reducing action of soaps. W. SCHRAUTH. *Seifensieder-Ztg.* 42, 369-71(1915).—In medicated soaps, especially those containing Hg, the soap base frequently has a reducing action. Soaps made from the satd. fatty acids do not possess a reducing action while those made from the unsatd. do. S. made some expts. with organic compds. of Hg in both Na and K soaps of satd. and unsatd. fatty acids, and the practical conclusions derived are that tallow, coconut and palm kernel oil may be used as a satisfactory soap base, but that bone greases and lard are unsuitable, also most vegetable oils.

E. SCHERUBEL.

The composition of foreign soaps. K. BRAUN. *Seifensieder-Ztg.* 42, 326-7(1915).—Analyses are given of Sunlight and Pear's soap, Roger & Gallet toilet soap, Thompson's soap powder and Minlo's washing powder.

E. SCHERUBEL.

Household soaps. ERNE. *Seifensieder-Ztg.* 42, 26-7(1915).—Discussion of substitutes for previous raw materials.

E. SCHERUBEL.

Foreign bath soaps. K. BRAUN. *Seifenfabr.* 35, 389-91(1915).—Analysis of English, French and Italian soaps.

E. SCHERUBEL.

Digitonin method for sterols in strophanthus oil (MATTHES) 17. Alcoholic rosin solutions (PRAGER) 26. Analysis of fatty substances 12. Rubber substitutes from oxidized oils (CHARDET) 30.

GANSWINDT, A.: *Moderne Seifenfabrikation*. Leipzig: B. F. Voigt. 228 ss. 7.50 M.

U. S., 1,141,104, June 1. A. B. CARR. Preparing cottonseed for storage in bulk by heating to 130–80° (F.?) partially to cook or coagulate the albuminous constituents without destroying their germinating quality, while protected from the air, and then cooling to 32–80° (F.?) to prevent continuation of the cooking when stored in bulk.

U. S., 1,142,668, June 8. G. CALVERT. Hydrogenating oils. A mixt. of the oil, *e. g.*, cottonseed or whale oil, with H and a catalyst, is heated under a pressure of above 250 lbs. per sq. in. in a closed vessel fitted with a beater which is so operated as to give a series of rapid impacts on the mixt. Cf. *C. A.* 9, 531.

Brit., 3,344, Feb. 9, 1914. O. C. HAGEMANN and C. BASKERVILLE. Carrying out catalytic reactions in liquids, particularly the hydrogenation of oils, fats, and fatty acids. See U. S., 1,083,930 (*C. A.* 8, 1025).

Ger., 281,146, July 7, 1912. B. BENEDEX. Mfg. fatty, soap-like products from hydrocarbons, for laundry and like purposes.

Ger., 281,329, Dec. 3, 1913. Addition to 259,360 (*C. A.* 7, 3000). H. OCKELMANN and O. OCKELMANN. Mfg. a stain-removing preparation by adding to the alk. soap obtained according to 280,688 (*C. A.* 9, 1553) a substance which permits the admixt. of sugar and thereby the taking up of a considerable amt. of KOH. Alc. is specified as such a substance. The various alcs., also oxidation products of alc., such as aldehyde and ketone, can be employed, especially the derivs. of alc. The higher the alc. content, within certain limits, the larger the amts. of sugar which can be incorporated. *E. g.*, for a soft soap, use sugar 2000 g., soap 2000 g., KOH 80 g., alc. 120 g., and for a hard soap, use soap 1500 g., sugar 500 g., KOH 19 g., and alc. 30 g. The alc. offsets the undesirable thickening effect of the sugar in the soln.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

The proteins in rubber and in latex. F. FRANK. *The Rubber Industry* 1914, 144–8.—The proteins were obtained free from the rubber by boiling 1 to 2 g. of the rubber in cymene, limonene or dipentene until a uniformly thin soln. resulted, and then centrifuging. They were washed with xylene, benzene and ether. This method can be used for the quant. detn. of N with good comparative results. The products obtained by this method gave the biuret reaction, the xanthoproteic reaction and PbS reaction for proteins. Millon's reagent gave marked reactions for the presence of tyrosine groups. Liebermann's reaction proved unreliable but all pptn. reactions characteristic of the known albumins were observed with certainty. The proteins were hydrolyzed with H₂SO₄ and the products of hydrolysis detd. The following groups were identified: monoaminocarboxylic acids, amino acids of the aromatic series (phenylalanine, and tyrosine), amino acids of the heterocyclic groups (tryptophan certainly), diaminomono-carboxylic acids and also with fair certainty monoaminodicarboxylic acids and cystine. In rubbers which externally show slight signs of disintegration the presence of amino acids can always be proven. In the discussion which followed the

paper it was pointed out that in the detn. as carried out, some of the amino acids would be sol. in the solvents used and thus be lost for the detn. W. F. ZIMMERLI.

The effect of acids and alkalis on rubber, more especially in relation to reclaimed rubber. W. G. MARTIN. *The Rubber Industry* 1914, 205-11.—A standard compd., fine Para 38.25%, ZnO 60% and S 1.75% was mixed with different amts. of powdered NaOH (0.25, 0.5, 0.75, 1, 3 and 5%) and vulcanized. Using NaOH up to 0.5% the vulcanization was accelerated; above that amt. it was retarded. The influence of acid was detd. by using the standard compd., fine Para 38.25%, BaSO₄ 60% and S 1.75%, and adding different amts. of H₂SO₄. It was found that even as small an amt. of acid as 1/8% retarded the vulcanization so that the product obtained was poor. 1-3% acid produced a porous vulcanized product. W. F. ZIMMERLI.

Recent advances in the analysis and evaluation of rubber and rubber goods. PHILIP SCHIDROWITZ. *Analyst* 40, 223-33(1915).—A review. P. B. DUNBAR.

Experiments on the determination of mineral matter in rubber mixings. B. D. PORRITT AND R. WHEATLEY. *The Rubber Industry* 1914, 193-9.—An attempt was made to break down the rubber by treatment with O₂, but good results were not obtained because some of the rubber remained unattacked. This may be due to the combined S forming a product which is unaffected by O₂. W. F. ZIMMERLI.

A simple method for the estimation of mineral matters in vulcanized rubbers. H. W. JONES. *The Rubber Industry* 1914, 199-201.—Two g. rubber are dissolved by heating with 40-50 cc. of PhNO₃ in a 200-300 cc. flask. After cooling, the flask is filled with acetone and the contents mixed. The mineral matter deposits quickly and is washed with acetone by decantation and weighed. W. F. ZIMMERLI.

The estimation of bitumens in rubber mixings. B. D. PORRITT AND E. ANDERSON. *The Rubber Industry* 1914, 181-9.—The results obtained with old methods for detg. bitumens in vulcanized rubber by extg. with different solvents were unreliable. It was hoped to devise a reliable method using the property of the insolubility of bitumens in HNO₃ (sp. gr. 1.355). The rubber to be analyzed is dissolved in HNO₃ and the bitumens filtered through a Gooch. The residue was then extd. with CS₂ and the ext. weighed. The method did not prove satisfactory. W. F. ZIMMERLI.

Use of nitric acid as a solvent for compounded and vulcanized rubbers. H. W. JONES. *The Rubber Industry* 1914, 189-90.—Carbonaceous constituents (lamp-black and hydrocarbons) may be detd. with fair results by dissolving 1-2 g. of the rubber in 40 cc. HNO₃ (sp. gr. 1.42) on the steam bath. The mixt. is filtered on asbestos after cooling and washed with cold HNO₃ and finally with H₂O. The residue can be weighed directly, or ignited and weighed to get % carbonaceous matter. W. F. ZIMMERLI.

Variability (of plantation rubber). P. SCHIDROWITZ. *The Rubber Industry* 1914, 212-29.—A brief general account of the principles underlying the methods of evaluation by vulcanization tests approved by the committee on standardization appointed by the Rubber Growers' Assoc. Details are to be published in sep. papers. The rubber is evaluated by giving marks for: (1) tensile work done on taking test piece to the break, (2) type (general mechanical properties, such as capacity for work, elasticity, recovery, rate of increase of resistance to stretch), (3) curing capacity, physical conditions and stability. The marks given by the above tests are added and compared to a standard which is 1000 marks. The results of applying the method to 67 rubbers are given in tables to show the variability of rubbers. W. F. ZIMMERLI.

Some American methods of testing mechanical rubber goods. D. E. DOURY. *The Rubber Industry* 1914, 230-45.—Outline of the methods of physical tests described in the U. S. Bur. of Standards, *Circ.* No. 38. W. F. Z.

The influence of temperature on the tensile properties of rubber compounds. P. L. WORMELEY. *The Rubber Industry* 1914, 246-58.—W. studied the influence of change of temp. on elasticity, tensile strength and ultimate elongation. He found that in measuring the thickness of the test pieces with a spring micrometer, the effect of expansion due to a rise in temp. is balanced to such an extent by the softening of the rubber that the variation in measured thickness rarely exceeds 1%. Although no fixed relation could be found, it was shown that temp. changes such as usually occur in a testing lab. greatly affect the physical properties of rubber. Elasticity increases, the tensile strength decreases, and the elongation increases with rise of temp. The tensile strength is affected to a less extent in high than in low grade rubbers. W. F. Z.

The depolymerization of raw rubber. A. VAN ROSSEM. *The Rubber Industry* 1914, 149-55.—1% solns. of plantation crepe in xylene were heated to 130° in an app. in which the soln. could be exposed to a gas, and the gas absorbed detd. The rubber soln. was exposed to O, H, N, and CO₂ and the change in viscosity of the soln. as well as the amt. of the gas absorbed detd. at different time intervals. It was found that the O was not absorbed until a definite limit of relative viscosity was obtained (after 8 to 10 hrs.). H, N and CO₂ were not absorbed, and the reduction of the viscosity of the soln. when exposed to these gases was not nearly as rapid as in the case where O was used. From this the conclusion is drawn that O has a catalytic action on the acceleration of the depolymerization of rubber, and that oxidation takes place after depolymerization. Oxidation is, therefore, only a secondary process in the phenomenon of the tackiness of rubber. W. F. ZIMMERLI.

The rubber solutions vulcanized by ultraviolet rays. A. HELBRONNER AND G. BERNSTEIN. *The Rubber Industry* 1914, 156-63; cf. C. A. 8, 2815.—The viscosity of rubber solns. is reduced with increasing amts. of S added. Rubber solns. containing different amts. of S were exposed to ultraviolet rays for different time intervals and the degree of vulcanization (or increase in viscosity) was detd. by cementing 2 pieces of fabric together by means of the soln. and detg. the degree of resistance to sepn. of the 2 plies. The degree of vulcanization (increase in combined S) depends on the concn. of S in the rubber and on the thickness of the film exposed to the light. Solns. of rubber vulcanized with ultraviolet rays are permanent, and if the operation is carried out in the proper manner, will remain const. for a long time. Besides rubberizing cloth the solns. can be used for very important cements (joining and rubberizing leather, and repairs of rubber goods). In using these solns. for joining 2 pieces of rubber a positive absorption of the soln. is obtained, and the 2 pieces of rubber are not sepd. by a layer of rubber (as is the case where ordinary cements are used). W. F. ZIMMERLI.

Vulcanization. G. BERNSTEIN. *The Rubber Industry* 1914, 164-71; see Helbrunner and B., C. A. 8, 2815. W. F. ZIMMERLI.

The mass action of sulfur in vulcanization. H. SKELLON. *The Rubber Industry* 1914, 172-80; cf. C. A. 7, 3670; 8, 262, 1678.—S. vulcanized very thin sheets of rubber mixings containing different amts. of S for different time intervals at 140° and detd. the combined S. The sheets were 0.020 in. thick with a variation of not more than 0.0015 in. They were vulcanized on an iron tube, covered with tin foil and wet cloth. Curves were drawn to represent the results. A max. point for combined S was noted in mixings containing 3, 5, 10, 20, 30, 40 and 50% S, vulcanized for 0.5, 1, 1.5, 3, 6 and 9 hrs. In the graphs representing the above as coeffs. of vulcanization, the max. of combined S is emphasized by the appearance of a flat portion on the curve. The incline on this flat portion of the curve increases with increasing time, and is probably due to the influence of the mol. effect of the S not dissolved in the rubber on the rubber-S phase; or to the greater excess of undissolved S causing the rubber-S phase to keep more

const., and also to the easier formation of polyprrene polysulfides which would increase the velocity of the reaction. In the case of the long cure on the rubber containing 50% S, the coeff. of vulcanization reached above 50% as against the theoretical 47%. This rubber was found to contain a new kind of "free S" which could be extd. with acetone only under pressure. W. F. ZIMMERLI.

The coagulation of the latex of *Hevea brasiliensis* and its bearing on the strength of the rubber. N. W. BARRITT. *The Rubber Industry* 1914, 130-6; cf. *C. A.* 8, 2266.—Fresh latex and aq. solns. of Na_2SO_4 and AcOH were used in the expts. Increasing the amt. of salt soln. without changing the acid strength resulted in a stronger vulcanized product, while increasing the acid decreased the strength. Dilg. the latex caused a poorer coagulation and a rubber of poorer strength. W. F. ZIMMERLI.

The chemical coagulation of rubber latex. F. KAYE. *The Rubber Industry* 1914, 137-43.—The latex, after coagulation with acid, showed more acid than was introduced for coagulation. This is probably due to H_3PO_4 formed by the hydrolysis of proteins. A standardization of coagulation is difficult when acid is used because of the variability of the action of enzymes on the proteins when the period lapsing before coagulation varies; and also to the different states of diln. and temp. which influence the hydrolysis. W. F. ZIMMERLI.

Synoptical tables of the different varieties of commercial raw rubber. D. SPENCE. *The Rubber Industry* 1914, 23-32.—Tables of the different varieties of rubber, giving the trade name, geographic origin, chief export center, botanical origin, loss on washing, and the resin content. W. F. ZIMMERLI.

The systematic study of rubber production. R. N. LYNE. *The Rubber Industry* 1914, 35-44.—The work being done in research on rubber is described and a plea is made for more extensive investigation. W. F. Z.

A comparison between wild and plantation-grown rubber. A. IRVING. *The Rubber Industry* 1914, 45-57. W. F. Z.

The rubber plantations of Angola. C. DE M. GERALDES. *The Rubber Industry* 1914, 71-4.—Instead of allowing the latex to coagulate on the tree as is usually done with *Manihot*, it is successfully collected and coagulated in bulk. Good yields of rubber are obtained. W. F. Z.

Rubber cultivation in Cochin China. A. CREMAZY. *The Rubber Industry* 1914, 75-83.—The Brazilian method of coagulating with smoke is used successfully. W. F. Z.

Kelantan as a rubber producer. T. C. HUTCHINGS. *The Rubber Industry* 1914, 84-6.—Growth of rubber trees is favorable but labor is high. W. F. ZIMMERLI.

Cultivation of rubber-growing vines in Central Africa. E. DE WILDMAN. *The Rubber Industry* 1914, 87-95. W. F. Z.

Notes on the Philippine rubber question. O. W. BARRETT. *The Rubber Industry* 1914, 96-100. W. F. Z.

The best and most economical methods of tapping. W. F. DEB. MACLAREN. *The Rubber Industry* 1914, 101-13. W. F. Z.

Notes on the physiology of the latex production in *Hevea*. R. H. LOCK. *The Rubber Industry* 1914, 114-23. W. F. Z.

Observations and comparative tests of latex of wild and plantation *Hevea*. F. RIPAUV. *The Rubber Industry* 1914, 124-9.—R. found that, on coagulating *Hevea* latex by means of CO_2 , a product was obtained equal to plantation smoked sheets. Good results were obtained by adding a dil. soln. of creosote to the latex. Coagulation

should not be hastened by heating or by the addition of acids. The coagulum should not be subjected to any mechanical working. H. B. SLUSSER.

Rubberized balloon fabrics. G. BARR. *The Rubber Industry* 1914, 259-75.—Properties and testing of rubber balloon fabrics. W. F. Z.

Synthetic rubber. Researches on the commercial preparation of isoprene. G. CHARDET. *The Rubber Industry* 1914, 276-9.—A mixt. of resin oil vapor and H was passed over metallic cloth (Fe) heated to dull redness. The condensed product was treated with CaCl_2 to dehydrate it, and then rectified. An av. of 8-12% isoprene was obtained. As by-products dipentene (b. p. 170°), some cymene, and some phenanthrene were obtained. Similar results can be obtained starting with naphtha oils.

W. F. ZIMMERLI.

Substitutes derived from oxidized oils. G. CHARDET. *The Rubber Industry* 1914, 280-3.—C. finds that oils are "hardened" more quickly by passing ozone into the heated oil containing 1% Mn resinate and suggests this method for making linoleum and rubber substitutes.

W. F. ZIMMERLI.

The advantages and defects of plantation rubber. W. A. WILLIAMS. *The Rubber Industry* 1914, 284-97.

W. F. Z.

Balata in rubber compounds. *Holland Ryksvoorlichtingsdienst*; through *Gummi-Ztg.* 29, 610-1 (1915); cf. *Ind. Rub. World* Nov., 1910, 49; *Gummi-Ztg.* 25, 460 and 569.—As a result of a few expts. for which the above gives the results of mechanical tests, it is concluded that, provided the price is not too high, balata may be substituted for the usual fillers to give strength and toughness. In small amts. it may be quite generally used with profit.

E. L. DAVIES.

The manufacture of balata. M. W. TER LAAG. *Caoutchouc et gutta-percha* 134, 8619-20 (1915).—A criticism of the process.

U. S., 1,42,526, June 8. C. E. MILLER. **Apparatus for vulcanizing rubber pneumatic tires.**

Brit., 2,070, Jan. 26, 1914. F. E. MATTHEWS and E. H. STRANGE. Natural or synthetic caoutchouc and caoutchouc-like substances are treated with liquid SO_2 to produce compds. of caoutchouc, etc., which resemble caoutchouc. In an example, synthetic rubber produced by the action of Na on butadiene is dissolved in benzene, and the cooled soln. is sealed up with liquid SO_2 . After heating at 40° for some time, the vessel is opened and, on evapn. to dryness, an elastic product results which may be mixed with fillers, untreated rubber, S, or other vulcanization agent and vulcanized according to the amt. of "vulcanization" which has already been effected by the SO_2 .

Brit., 2,281, Jan. 28, 1914. F. RIPRAU. **Coagulating latex** by means of smoke in shallow pans, supported on frames. The rubber is removed as sheets from the pans, and may be gently pressed. If desired, after the rubber is coagulated, the sheet may be turned over and again treated with smoke, or further layers may be superposed upon the original layer.

Brit., 2,336, Jan. 29, 1914. A. JOHNSTON and NORTH BRITISH RUBBER CO. Rubber floorings, pavings, and like coverings are formed by vulcanizing directly on the floor or road a layer of unvulcanized rubber by means of steam plates, hot plates, or other device, or by chem. vulcanizing agents such as S_2Cl_2 , etc. The surface to be covered may be metal, concrete, or other material; the finished rubber surface is without joints. The rubber may be in the form of finely-divided particles of vulcanized or unvulcanized rubber mixed with vulcanizing ingredients, and be then reformed under pressure and heat. A non-slip pattern may be molded on top.

Brit., 2,627, Jan. 31, 1914. H. A. WICKHAM. In latex-coagulating apparatus of the rotary type, such as is described in 7,371, 1907, in which a film of latex is treated with smoke and other agents, a fixed housing completely or partly enclosing the rotating member is divided by a partition, and the latex-delivery conduit is traversed so as to distribute the latex over the moving surface. Cf. C. A. 9, 732.

Brit., 3,158, Feb. 6, 1914. W. E. MUNTZ. Rubber goods employing a foundation fabric are impregnated with gases or vapors for which SO_2 and H_2SO_4 have a stronger affinity than they have for the foundation fabric. Examples of the substances that may be used are NH_3 and substances of an alk. nature, such as the higher alkylamines, that are capable of being vaporized by heat or by reagents which do not injure the goods. The vapors, etc., may be generated independently or from substances in the goods. The goods may be impregnated by 1st subjecting them to vacuum and then applying the gas, etc., under pressure.

Ger., 281,262, Dec. 23, 1910. Addition to 277,653 (C. A. 9, 1136). J. STOCKHAUSEN. Process of mfg. plastic or elastic masses. Cf. Brit., 23,630, 1911 (C. A. 7, 1299).

CHEMICAL ABSTRACTS

Vol. 9.

AUGUST 10, 1915.

No. 15.

I. APPARATUS.

L. C. JONES.

A simple apparatus for purification of viscous substances. F. F. BLICKE. Charlottenburg. *Chem. Ztg.* 39, 424(1915).—A glass crucible is suspended in a wide-mouth flask by means of a wire passing up through the return cooler. The substance in the crucible is covered with a fine wire gauze to prevent floating out, and a small funnel supported by the wire drops the condensed solvent on the center of the gauze.

J. H. MOORE.

Synthermal regulator, a device for automatically maintaining an adiabatic condition in calorimetry. T. W. RICHARDS AND G. D. OSGOOD. *J. Am. Chem. Soc.* 37, 1718-20(1915).—A delicate differential H thermometer was devised which, in connection with a relay, operates a heating or cooling mechanism for causing one bath to follow the temp. of another within 0.03°.

E. B. MILLARD.

Improved quartz mercury vapor lamp for biological and photochemical investigations. W. T. BOVIE. *J. Am. Chem. Soc.* 37, 1721-6(1915); cf. *C. A.* 9, 1340.—The lamp consists of a quartz tube 70 cm. long, closed at one end by an invar stopper and inverted in a cistern of Hg. The principles of the Hg air pump have been incorporated into the design so that no pump is required to exhaust the lamp. It can be reëxhausted in a minute without disturbing the substance under investigation and without interrupting the exposure for more than a fraction of a minute.

E. B. MILLARD.

Apparatus for determining the melting point of paraffin waxes. F. H. SMALL. *J. Am. Leather Chem. Assoc.* 10, 144-6(1915).—A glass tube, the graduated lower part of which is the smaller, is closed at the bottom, receives the wax in the larger upper part and is nearly immersed in a vessel of water whose temp. is gradually raised. The amts. of liquid collecting in the graduated portion at successive temps. are observed, thus giving an approx. estimate of the % melting at each temp.

L. B.

A modification of the Bellani porous plate atmometer. B. E. LIVINGSTON. *Science* 41, 872-4(1915).—A discussion of various forms of atmometers with a detailed description of a modified form of the Bellani app.

F. W. SMITHER.

Approved safety lamps. *Colliery Guardian* 109, 910-2(1915).—The safety lamps order of March 16, 1915, issued by the Home Secretary.

H. L. OLIN.

Some fireproof specialties for chemical and metallurgical purposes. K. ENDELL. Charlottenburg. *Chem. Ztg.* 39, 421-2(1915).—General remarks on app. the principle constituent of which is either clays, pure oxides, or carbides.

J. H. MOORE.

A new blast-compressor. ANON. *Chem. Ztg.* 39, 400(1915).—A small motor blast driven from the lighting circuit.

J. H. MOORE.

Sprays for cooling water. ANON. *Met. Chem. Eng.* 13, 401(1915).—A brief discussion of the use of sprays for cooling water and for washing and cooling air. A new nozzle, manufd. by the Spray Eng. Co., Boston, is illustrated. The advantage claimed over the well-known types is a central jet so placed as to give a solid cone of spray instead of a hollow cone.

W. L. BADGER.

Ice calorimeter (GRIFFITHS) 2.

Brit., 4,482, Feb. 20, 1914. A. FERRARIS. Pumps for corrosive liquids of the type wherein a body of inert liquid, such as oil, is interposed between the piston and the corrosive liquid.

Brit., 4,657, Feb. 23, 1914. SILKEBORG MASKINFABRIK ZEUTHEN & LARSEN. A machine for making emulsions, as in the manuf. of margarine, consists of a vessel through which the material flows continually and which contains stirrers alternating with perforated partitions. The stirrers consist of disks attached to a horizontal shaft and formed with slots, the edges of which are turned up so as to produce a propeller. One set of partitions is perforated with small holes, and the other set is wheel-shaped. The size of the perforations diminishes from the inlet end of the machine to the outlet end.

Brit., 4,828, Feb. 24, 1914. E. OLIVIER-ALPHAND. Filters comprizing sleeves of filter cloth doubled over cylindrical metal cages so as to form annular chambers.

Ger., 279,360, Mar. 12, 1914. AKT.-GES. DER MASCHINENFABRIKEN ESCHER WYSS & CIE. Automatic return of a liquid lubricant from the vaporizer in the exhaustion chamber of a refrigerating machine.

Ger., 279,465, Apr. 15, 1913. L. A. RIEDINGER. MASCHINEN- UND BRONZEWAREN-FABRIK A.-G. Safety device for the pressure system of refrigerating machines.

Ger., 280,696, Apr. 5, 1911. E. ALTENKIRCH and G. GEHLHOFF. Thermoelectric cooling and heating body, comprizing a series of thermopiles connected in parallel with a source of current, contacting with each other at the points of welding, and being arranged mutually so that the warm junction, say of an inner element, is next to an outer element.

Ger., 280,977, May 7, 1913. CARL ZÜBLIN. App. for evaporating liquids or drying and superheating vapors or gases by direct contact of the substances with the heating flame, on the surface-combustion principle.

Ger., 281,127, Oct. 22, 1912. KÖNIG FRIEDRICH AUGUST-HÜTTE. A trough drying apparatus with an endless screw designed to comminute the material during its passage through the trough.

Ger., 281,128, Sept. 17, 1913. K. ROSS. App. for saturating liquids with gas, especially for satg. H_2O with CO_2 .

Ger., 281,156, Nov. 6, 1913. P. P. STEIN. Device for permitting reading of a thermometer in the dark, comprizing a float carrying radioactive material.

Ger., 281,263, June 12, 1914. G. VOGEL. Welding burner.

Ger., 281,284, Apr. 13, 1911. W. GENSECKE. App. for heating the condensate for the purpose of recovering the waste heat in condensers provided with several steam jets for removing the air and non-condensable gases.

Ger., 281,492, Nov. 28, 1913. G. W. BARTH. A sampler for use with roasting drums and the like.

Ger., 281,526, Nov. 15, 1913. C. A. HARTUNG. Automatic device for mixing gases, vapors, or liquids in definite proportions, with another gas, vapor, or liquid, flowing in closed tubes.

Ger., 281,527, Dec. 14, 1913. C. H. MATTERN. Electric device for determining vapor density.

Ger., 281,552, Nov. 13, 1913. ALLGEMEINE ELEKTRIZITÄTSGES. Constructional details of rotary compressors, whereby a smooth flow of the medium is insured.

Ger., 281,670, Dec. 23, 1913. W. BUSS. A stopcock for liquids or gases provided with a removable sieve mounted in the plug. This sieve is designed to incline downwardly, during the passage of the liquid or gas, in the direction of flow. A small chamber is provided under the sieve to receive solid matter removed from the current thereby.

Ger., 281,693, May 26, 1912. W. GENSECKE. App. for removing the air and the uncondensable vapors from condensers.

Ger., 281,727, Feb. 7, 1914. AKT.-GES. BROWN, BOVERI & CIE. Hg app. for producing a vacuum or condensing gases or vapors, wherein the Hg (or other elec. conducting liquid) is kept in circulation in a closed chamber by means of a current induced by a magnetic field, and effects the exhaustion or condensation of the gas or vapor.

Ger., 281,765, Oct. 14, 1913. Addition to 233,516 (C. A. 6, 1695). W. A. RUCKER. Modification in the construction of the device specified in the principal patent for regulating the temperature in chemical digestion flasks, and the like.

Ger., 281,889, June 12, 1913. P. HEINRICH. Construction of a color atomizer (air brush).

Ger., 281,918, Dec. 9, 1913. J. FRISCH & Co. Glass vessel for observing colors of liquids or solns., especially in titrations, is provided with an enamel interior or exterior coating, extending over the bottom and up the sides to any desired height, and in a color suited to the purpose for which it is to be used. This enamel provides a constant and permanent background or base. A vessel with enamel extending up the sides to some height permits observation of the color of the liquid contents only by reflected light by looking down into the liquid diagonally. If, however, the enamelling does not extend so high, say a few mm. only, the vessel serves also for the observation of color by transmitted light. The vessel may be placed on any surface without influencing the appearance of the liquid contents.

Ger., 282,128, July 12, 1913. H. TRAUN & SONS, v. HARBURGER GUMMIKAMM Co. A container for hydrofluoric acid consists of a vulcanizable mixt. of rubber and an impermeable substance, such as paraffin, which is not attacked by HF. The paraffin or gutta-percha, or a mixt. of these, is added to the vulcanizable mixt., and the resulting mass is vulcanized. The resulting containers combine high mechanical strength with chem. inactivity, and prevent diffusion. According to the concn. of the HF, up to 15% paraffin, calculated to the amt. of the pure hard rubber, is used. The temp. of vulcanization may be 145-150°.

Ger., 282,172, Feb. 19, 1914. J. ACKER, E. SCHMITZ, L. GOURWITSCH. App. for taking average samples, as of naphtha and the like, from liquid containers, consisting of a hollow cylinder which is lowered and raised by means of a suitable mechanism.

Ital., 129,756, 397-76, Feb. 27, 1913. P. RIBONI and A. BIBOLINI. App. for separating the constituents of a mineral or other mixture, dependent upon the difference in the dielec. constants of the constituents. The initial material is subjected to the influence of a suitable electrostatic field.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: A. B. CARTER and E. B. MILLARD.

Compressibilities of the elements and their relations to other properties. T. W. RICHARDS. *J. Am. Chem. Soc.* 37, 1643-56(1915); cf. *C. A.* 8, 1896, 3523; 9, 399.—

The data on this subject in *Publication Carnegie Inst.* 76(1907), which were referred to a questionable value for the compressibility of Hg, are now corrected by use of the new absolute value 0.00000395 (cf. *C. A.* 9, 983) at 20°, in place of the value 0.00000379 previously used. The compressibility of ice is less than that of H₂O in spite of the greater vol. of the former. Similarly, solid *o*-cresol and *p*-cresol in the solid state have the values 23.8×10^{-6} and 21.8×10^{-6} , resp., between 300 and 500 megabars, while the corresponding quantities for the liquid are 42.1×10^{-6} and 41.8×10^{-6} . A diagram is given for 35 solid elements in which the reciprocal of the abs. m. p., the coeff. of expansion, at. vol., and compressibility are shown to vary periodically when at. wts. are plotted against the other quantities mentioned. Density is not adequately represented by at. vol., since Au and Ag have nearly equal at. vols. and m. ps., yet quite different compressibilities. As usual, the more dense is the less compressible. The following (empirical) equation roughly represents the compressibility (β) as a function of the density (D), the abs. m. p. (T_m) and the at. wt. (A): $\beta = 0.00021A / D^{1.28}(T_m - 50^\circ)$.
E. B. MILLARD.

The dawn of modern chemistry. JOHN M. STILLMAN. *Pop. Sci. Monthly* 87, 5-21(1915).—This historical paper deals with the period beginning with the early 16th century and extending well toward the latter part of the 18th century.

E. J. C.

The method of "small vibrations" in atom-dynamics. R. SEELIGER. Charlottenburg. *Verh. deut. physik. Ges.* 16, 1042-50(1914).—Mathematical. C. D. W.

Applications of Thomson's theory of atoms and molecules to structural chemistry. B. SZYSZKOWSKI. *Svensk. Kem. Tidskrift* 27, 71-5(1915).—Each valence electron is connected to the atom by a tube of force which is anchored in the interior of the atom. When 2 atoms combine, the linking between them may be represented:

as $C \rightleftharpoons C$, or, more briefly, $C \equiv C$. Employing the briefer notation, the tautomer-

ism of acetoacetic ester was $CH_3 \cdot C(=O) = CH \cdot CO_2H$, $CH_3 \cdot C \equiv CH \cdot CO_2H$, $CH_3 \cdot C \equiv CH \cdot CO_2H$
(ketoform) (tautomer) (enol form)

where the 4-bonded C atoms should read $\rightleftharpoons$. The weakly aromatic character of naphthalene as compared with naphthoquinone was a direct consequence of its structure, for in the former there is no true aromatic ring with 6 C atoms linked $\rightleftharpoons$ while in naphtho-

quinone the left ring was a true aromatic ring, thus: and

Substitution could be shown by the arrangement $R \cdot C = H$
 $Cl = Cl \rightarrow$

$R \cdot C - H$
 $Cl - Cl \rightarrow$ Other cases more complicated were also taken up, from which

it was concluded that the theory made all reactions and properties of organic and inorganic compds. clear and easily represented, that the theory gave a true model of

the mol. and not merely a conventional representation of properties and reactions, and furnished a clear conception of valence. These claims were not wholly clear to the abstractor.

E. B. MILLARD.

Determination of a system of chemical equivalents by means of normal solutions. L. KLEIN. Heilbronn. *Z. physik. chem. Unterr.* 28, 90-4(1915).—The system outlined is for elementary work and is based on the neutralization of solns. of bases with acids, evapg. and weighing the resulting salts.

J. H. MOORE.

Extension of the dilution law to concentrated solutions. JAMES KENDALL. *J. Am. Chem. Soc.* 36, 1069-88(1914); cf. *C. A.* 6, 3043; 8, 1044.—The modified law developed was $\Delta^2/\Delta_0(\Delta_0 - \Delta)v' = K$, where v' was the number of unit weights of solvent employed to dissolve one equiv. wt. of total salt, and the other terms have their usual meaning. This equation and $n_u(n_u + n_i)v'/n_i^2 = \text{const.}$ are valid for all concns. of electrolyte, when n_u , n_i and n_s are the numbers of mol. wts. of unionized mols., ions and solvent, resp. The theoretical basis underlying this modification of the dilution law was that the dissociation of a binary electrolyte into its ions did not take place spontaneously, but by impact with the mols. of the solvent. The dissociating power of a solvent was ascribed to its unsatd. character, i. e., to free valences.

E. B. MILLARD.

Ammonia. I. General considerations. F. HABER. *Z. Elektrochem.* 20, 597-604 (1914); cf. *C. A.* 9, 515, 1423.—Summary and theoretical introduction referring to earlier and future papers (cf. following abstr.). The following substances served as catalysts for the combination of N with H: Os, U carbide, Mo, and W. When U carbide was used, the expression for the equil. for the formation of NH_3 for temps. up to 1100° and below 600° was the same as that when Os was the catalyzer between 560 and 974° , namely $\log K_p = (9591/4.571 T) - (4.98/1.985 \log T) - (0.00046/4.571 T) + (0.85 \times 10^{-8}/4.571 T^2) + 2.10$. The sp. heat of NH_3 gas may be represented by the equation $C_p = 8.62 + 0.0035t + 0.000005t^2$, and the heat of formation of NH_3 from N_2 and H_2 by $Q = 10950 + 4.85t - 0.00093t^2 - 0.0000017t^3$ cal. E. B. M.

Ammonia. VII. Ammonia equilibrium at ordinary pressures. III. F. HABER. Berlin-Dahlem. *Z. Elektrochem.* 21, 128-30(1915); cf. *C. A.* 8, 3101; 9, 515, 1423.—Approximate expts. with $1/4$ N and $3/4$ H at const. (atm.) pressure and 600 to 1100° , were made with Fe-asbestos or U carbides as catalyzer. The U carbide first changes to a nitride, which is an active catalyzer. The values of $K = p_{\text{NH}_3}/p_{\text{N}_2}^{1/2} p_{\text{H}_2}^{3/2}$ were detd. at each temp., as follows: at 1100° 0.92×10^{-4} , 1000° 1.38×10^{-4} , 850° 2.71×10^{-4} , 700° 6.57×10^{-4} , 600° 13.8×10^{-4} . At the higher temps. the agreement between these values and the calc. const. was complete, but at 600° and 700° the calc. values were somewhat higher than the observed. E. B. M.

Ammonium solutions. R. E. SLADE. *J. Chem. Soc.* 105, 1351-3(1914).—Corrections to the e. m. f. detns. of *J. Chem. Soc.* 99, 1974(1912) (*C. A.* 6, 564). The value $\epsilon_0 = -0.486$ should be decreased 0.170 in the equation for ϵ . Using Auerbach's value for the H electrode (*C. A.* 6, 1565), the value of ϵ at 25° should be $\epsilon = -0.654 - 0.059 \log [p_{\text{NH}_3} p_{\text{H}_2}^{1/2}/(\text{NH}_4^+)] = -0.551$ for $p_{\text{H}_2} = 1$ and $(\text{NH}_4^+) = 1$.

E. B. MILLARD.

Extension of Trouton's rule. S. ARRHENIUS. *Medd. K. Vetenskapsakad. Nobelinstit.* 3, No. 6, 9 pp.(1915).—For a large number of reactions the quotient Q/T was a "const." between 28 and 56, when the variations in Q and T were quite large. For the decompn. of HCl or HBr by heat the "consts." were 0.88 and 0.24, resp., but the temps. of decompn. were 50,000 and 100,000°, resp. The quotient Q/T had about double the value when the number of mols. increased 2 on decompn. that it had when the increase was 1 mol. (55.4 and 36.4, resp.). Deviations from a const. quo-

tient were much larger than could be accounted for by exptl. errors, even for reactions of the same type. The calcns. were preceded by some interesting speculations on the temp. of processes in the sun, where temps. of 3 or 4 million degrees are reached. Chem. reactions could not be the source of the heat from the sun, since if the sun were pure C its combustion would supply the radiated energy for only 4000 years at most.

E. B. MILLARD.

Dissociation of electrolytes as a function of the neutral molecule. B. DE SZYSZKOWSKI. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 2, 1-49 (1915); cf. *C. A.* 8, 1364.—Using the data of Kohlrausch, K. and Maltby, and Kendall (*C. A.* 8, 1044), S. has discussed the general dissociation functions of electrolytes of all types up to 0.5 *N*, and has given $D = K + k(C_0^{1/2})^m$ as the equation best representing the data. $D = \alpha^2 C / (1 - \alpha)$, where α is the degree of dissociation, *C* is conc., *K* is the proper dissoc. const., *k* is another dissoc. const., *m* is a const. between 1.0 and 1.35, and *C*₀ is the conc. of unionized mols. The Δ° values given in the original data have not been tampered with in any case. Tables are given for the cond. of 34 electrolytes of such various types as KCl, KCNS, CHCl₃COOH, C₆H₅(NO₂)₂COOH, H₂PO₄ and β -resorcylic acid in H₂O, together with calcd. values of the activity coeffs. of the neutral mols., *k*, *K* and *m*. All of the values of *m* are between 1.00 and 1.35, and most of them are below 1.2. Evidence has been given in support of the theory of Walker (*Rep. British Assn.* 1911, p. 349; *C. A.* 5, 3645) and of Lewis (*Z. physik. Chem.* 70, 218 (1909); *C. A.* 3, 2399) that the deviations of strong electrolytes are due to the neutral mols., and not to the ions, since organic acids obey the mass law at ion concns. 1000 times as great as those at which salts begin to show considerable deviations. The power of the neutral mol. to increase the dissociation has been expressed for all of the electrolytes investigated by means of the "activity coeff." *a*, which varied between 6.0 and almost zero, the smallest value detd. being 0.00025. The existence of a proper dissoc. const. *K* for strong electrolytes as first suggested by Arrhenius has been definitely proved, its order of magnitude for salts being 0.01.

E. B. MILLARD.

Distribution of dinitrobenzoic acid between benzene and water. BOHDAN DE SZYSZKOWSKI. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 3, 7 pp. (1915); cf. *C. A.* 8, 1365.—The distribution expts. have been carried out by the method previously used, for 1,3,5-dinitrobenzoic acid between C₆H₆ and H₂O. [The temp. of these expts. was not given, but seems to be 25° from the other papers.—ABSTR.] As the mol. concn. of the H₂O layer decreased from 0.0063 to 0.0010, the ratio of the concn. of unionized mols. in this layer to the concn. of the C₆H₆ layer decreased steadily from 0.437 to 0.277. This shows that the C₆H₅(NO₂)₂COOH is more associated in H₂O than in C₆H₆, which is in direct contradiction to the Nernst-Thompson rule relating association to dielectric const. Calcns. are given to show that the coeff. of distribution between the phases was 0.625 for the simple mols. and 0.875 for the double mols. when the liquids were CHCl₃ and H₂O, and the distribution coeff. of the double mols. between C₆H₆ and H₂O was calc. as 1.77. The order of the consts. $w^2/(c_0 - w) = W$ and $m^2/(c_B - m) = B$, where *c*₀ was the total conc. of undissociated mols. in H₂O, *w* the concn. of simple mols. in H₂O (therefore (*c*₀ - *w*) was the concn. of double mols. in H₂O), *m* the concn. of simple mols. in the C₆H₆ phase and *c*_B the total concn. in this phase, was shown to be independent of the nature of the solvent in the non-aq. phase, by expts. with CHCl₃ in place of C₆H₆. *W* was 0.0016 and *B* was 0.0036 in CHCl₃, and the corresponding values in C₆H₆ were 0.00158 and 0.048. This was claimed to be the first case of association of an organic acid in H₂O. Cf. following abst. E. B. MILLARD.

Hydrates and complex molecules in non-associated solvents. BOHDAN DE SZYSZKOWSKI. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 4, 26 pp. (1915); cf. *C. A.* 8,

1364-5 and preceding abstr.—From the equations above and those of Hendrixson (*Z. anorg. Chem.*, 13, 73 (1897)), de S. has calcd. that the degree of hydration is independent of the concn. of the acid, from which it follows that the amount of H_2O in an organic solvent used in distribution expts. must be const. as well. A "real" dissociation const. has been used; allowance has been made for the hydrated mols., and it has been shown that a const. relation exists between the "real" distribution const. and that obtained by expt., when the degree of hydration is given. This degree of hydration may be detd. simply from the solubilities of the acid in dry C_6H_6 and in the same solvent satd. with H_2O when the latter detn. is made in the presence of an excess of both acid and H_2O , since the increased solubility in the presence of H_2O can only be due to the solution of hydrated mols. in the C_6H_6 . The "dry" C_6H_6 was a good commercial product used without further drying. From detns. in both dry and moist $CHCl_3$ and C_6H_6 , the hydration const. H has been detd. from benzoic, salicylic, *o*-nitrobenzoic and 1,3,5- $C_6H_3(NO_2)_3COOH$; $H = n.s/h$, where n was the concn. of non-hydrated simple mols., s the solubility of H_2O in the organic phase, and h the hydrated mols., and the value of H for the acids in the order named above was 0.0982, 0.133,, and 0.130. Further detns. of the solubility of 2 organic acids present in C_6H_6 simultaneously showed that each increased the solubility of the other by forming "complexes" contg. 2 mol. species. Calcns. are given for the dissociation const. of these complexes into the simple mols., and for simultaneous hydration and complex formation.

E. B. MILLARD.

Hydrated and complex molecules in non-associated solvents. BOHDAN DE SZYSZKOWSKI. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 9, 20 pp. (1915); cf. preceding absts.—Further consideration of the data on solubility and distribution. Systems of 3 and 4 acids have been considered. The affinity between 2 acids was very great in 2-component systems, especially between *m*- and *o*- $C_6H_4NO_2COOH$. Since each of these forms complexes with itself, the complexes here formed are probably between complexes of each as well as between simple mols. of each. From other considerations it was calcd. that 96% of the acid present was in the form of hydrated and solvated mols., and about 1% as associated mols. in a system in which all of the acids but one and H_2O were together considered the "solvent" for the other acid. The increase in the dissociation const. of an organic acid from concns. of 0.1 *N* to higher concns. cannot be due to viscosity changes alone, but may be explained by complex formation.

E. B. MILLARD.

Influence of temperature on the hydration and association of acids in benzene. BOHDAN DE SZYSZKOWSKI. *Medd. K. Vetenskapsakad.* 3, No. 10, 11 pp. (1915); cf. preceding absts.—The hydration increased with the temp. for the acids considered (salicylic, and *o*- and *m*-nitrobenzoic), at least over the temp. range 25 to 40°, since the solubility of H_2O in C_6H_6 increases with the temp. The hydrated mols. were also more dissociated at the higher temps., and this, together with the increased degree of dissociation of H_2O with increasing temp., explained why the increase of the real hydration const. was greater than that of the apparent const. These considerations are applicable only to cases of distribution between H_2O and a non-associated solvent.

E. B. MILLARD.

Solubility of electrolytes in salt solutions. BOHDAN DE SZYSZKOWSKI. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 5, 26 pp. (1915).—Expts. have been made on the solubility of 1,3,5- $C_6H_3(NO_2)_3COOH$ in H_2O and in solns. of KCl , $NaCl$, KNO_3 and $NaNO_3$ of various concns., and of *m*-aminobenzoic acid in the same solvents. These data and others of de S. have been used to prove theoretically and experimentally that the increased solvent effect produced by neutral salts upon the solubility of sparingly sol. electrolytes (which lead generally to maxima of solubility at a given salt concn.) was

a natural consequence of double decompn. and of the increase of affinity constant caused by the presence of the salt. The abnormal increase of solubility of salicylic acid, and especially of $1,3,5\text{-C}_6\text{H}_3(\text{NO}_2)_3\text{COOH}$, in nitrate solns. was ascribed in part to an individual solvent action exerted by the salt itself, since the increase was too great to be due to metathesis or increase of affinity const. alone. E. B. MILLARD.

Radiometric measurements of the ionization constants of indicators. II. M. G. PAULUS, J. F. HUTCHINSON AND H. C. JONES. *J. Am. Chem. Soc.* 37, 1694-704 (1915).—An intensification of the red color of rosolic acid solns. completely transformed by the addition of alkali was found to take place when such solns. were allowed to stand, the time reaction being in all probability due to a slow union of the metallic phenolate with the quinoid complex. In rosolic acid solns. contg. a large excess of alkali a perceptible bleaching of the red color was also indicated. The ratio (C/C_0) of the red to the yellow component has been detd. for indicator solns. of various H ion concn., using the radiometric method developed in the previous article (cf. *C. A.* 9, 1265). From this ratio the values calcd. for the ionization const. of rosolic acid, assuming the indicator to be monobasic, decreased with decreasing alkalinity. When the H ion concn. was increased from 2.533×10^{-8} to 19.52×10^{-8} , the total salt concn. being 0.0259 *N*, the value of the ionization const. K_i was found to decrease from 5.65×10^{-8} to 2.89×10^{-8} . This variation of the consts. could be explained by regarding the indicator as a dibasic acid, and it was shown that the intensely colored form of the indicator was formed when the first H of the indicator was replaced by the base. E. B. M.

The apparent slowness of hydrolysis of ferric salts. A. QUARTAROLI. Univ. Pisa. *Gazz. chim. ital.* 45, I, 139-52 (1915).—Certain reactions in aq. solns. are not fast enough to be considered instantaneous. The hydrolysis of salts requires relatively considerable time. The soln. obtained on dilg. such salts only comes to equil. after weeks or months. Thus the HCl increases, the color changes and the Tyndall effect becomes gradually more marked with time when a conc. FeCl_3 soln. is dild. Goodwin (*Z. physik. Chem.* 21, 1 (1896)) studied the case of FeCl_3 and concluded: (1) that the mol. cond. of the solns. increases with time and the velocity of increase increases rapidly with the dilm., (2) that the increase in cond. is not immediate but begins after a period that increases with the conc., and (3) that the period necessary to reach equil. increases enormously with the conc. G.'s explanation may be expressed thus: $\text{Fe}^{++} + \text{H}_2\text{O} \longrightarrow \text{FeOH}^+ + \text{H}^+$ and $x(\text{FeOH}) + 2x(\text{OH}) \longrightarrow (\text{Fe}(\text{OH})_3)_x$, in which the formation of the colloidal $\text{Fe}(\text{OH})_3$ seems to accelerate the whole process. Wagner (*C. A.* 8, 2644) suggested that colloidal $\text{Fe}(\text{OH})_3$ is formed at once, but that the course of the re-action is modified by a diminution in the degree of its dispersion. Neither G.'s nor W.'s interpretation permit of a direct demonstration. Q. proposes to study these questions by utilizing the magnetic properties as described recently. The Fe must be in the form of ions. Fe^{++} compds. in nondissociating solvents or in the colloidal form fail to show magnetic properties in soln. By the use of Quincke's method and the author's own modification previously described, comparable results were obtained. The intensity of the electromagnetic field was detd. by means of the variations of the resistance in a Bi spiral measured with a Wheatstone bridge or galvanometer. The field intensity was detd. with various current intensities and a curve was constructed so that with a known current a known field would be produced. The field used varied from 10000 to 25000 gauss. The methods of exposing the solns. and of comparing results were the same as those used previously. The magnetic susceptibility of the solns. of FeCl_3 of various concns. was detd. immediately after prepn. and at certain intervals until the values became constant, indicating that hydrolytic equil. had been reached. The elec. cond. for similar solns. at the same intervals was detd. The magnetic susceptibility detd. was corrected against that of H_2O . The H-ion conc. in the soln. when

equil. had been reached was detd. by the ethyl diazoacetate method. The expts. were all done at 25°. A conc. soln. of pure FeCl_3 was prepared. The Fe and Cl were detd. and enough HCl added to make the ratio 1:3. This soln. contained 110.36 g. FeCl_3 (0.6802 mol.) per l. and was used in all expts. Five cc. were used in each case and dild. to the degree required. Solns. of 0.06802 (5.8% hydrolyzed at equil.), 0.03401 (24.2% hydrolyzed), 0.01360 (45.6%), 0.00680 (60%), 0.00340 (78%), 0.001360 (91%), 0.000545 (94.8%), 0.000109 (94.8–100%) and 0.000054 mol. conc. were studied. The period at the end of which the final observation was made for the first 7 was 3 mos., 1 mo., 20 days, 7 days, 5 days, 2 days and 6 hrs., which indicates something of the relative rates of hydrolysis. At a dild. of 0.000054, at which other authors have pronounced the hydrolysis complete, Q. found that the magnetic susceptibility was still faintly positive, from which he concludes that not all of the Fe is in the colloidal state. Another series of expts. was carried out in which the effect of the addition of 10 cc. conc. HCl to 5 cc. FeCl_3 soln. before the above dilds. were prepared was studied. With the more dil. solns. the HCl did not produce any appreciable difference in the hydrolysis. A 3rd series of expts. was treated with K_2SO_4 to coagulate the colloidal $\text{Fe}(\text{OH})_3$. In these cases the hydrolysis was more rapid but the negative susceptibility at equil. was the same as when K_2SO_4 was absent. The results are discussed and are found to be contrary to Goodwin's results and in general support those of Wagner. The latter's explanation is modified somewhat by stating that the Fe is not all present in the colloidal form but is partly present as basic FeOHCl_2 and $\text{Fe}(\text{OH})_2\text{Cl}$, which cannot be much dissociated electrolytically. The general interpretation of the noninstantaneous hydrolysis of FeCl_3 is as follows: Immediately after the dild. the hydrolyzed portion of the salt is composed partly of FeOH^+ ions (and possibly $\text{Fe}(\text{OH})_2^+$) and partly of amicroscopic, colloidal granules of $(\text{Fe}(\text{OH})_3)_x$ or highly basic chlorides, the latter having a high degree of dispersion. These with their enormous surface adsorb a large amt. of HCl. Contrary to Goodwin's hypothesis the amt. of colloidal $\text{Fe}(\text{OH})_3$ remains unaltered from the beginning to the end of the reaction, but the degree of dispersion and thus the surface is diminished and part of the HCl is liberated. As the dild. increases the fraction of the hydrolyzed part consisting of ordinary ionized mols., FeOH^+ , $\text{Fe}(\text{OH})_2^+$, etc., increases in comparison with that existing in the colloidal state. Various authors have stated that in a soln. of 0.000054 mol. conc. FeCl_3 is completely hydrolyzed and exists wholly in the colloidal state, but by means of Q.'s sensitive method for detg. the magnetic susceptibility it is shown that this statement is incorrect. The failure of the $\text{K}_4\text{Fe}(\text{CN})_6$ reaction at this dild. and its appearance when HCl is added are not decisive observations, since even these authors do not believe that the reactions of Fe^{++} are the same as those of the ions FeOH^+ or $\text{Fe}(\text{OH})_2^+$.

E. J. WITZEMANN.

The significance of the dependence between magnetic susceptibility and dissociation. Association between ions and solvent. A. QUARTAROLI. Univ. Pisa. *Gazz. chim. ital.* 45, I, 153–60(1915); cf. preceding abstr.—It has been found that magnetic substances in dissociating solvents give solns. which are paramagnetic or less diamagnetic than the solvent. Magnetic substances in EtOH or Et_4O do not show any magnetic action. Thus the solvent and the dissociated part of the compd. seem to control the magnetic properties. The magnetic susceptibility should therefore increase with dild.; this has been verified variously. A similar increase was noticed (*l. c.*) in soln. to which HCl had been added in order to prevent hydrolysis. These statements may possibly only be true for dil. solns. since the presence of complex compds. and ions may complicate the explanation in these cases. The union of CN or O with the magnetic ion diminishes or destroys the strong atomic susceptibility. The results of this earlier work indicate a well defined relation between magnetic susceptibility and

electrolytic dissociation. The action of a magnetic field on a magnetic disperse system is discussed for the cases in which the disperse phase consists of (1) macroscopic granules, (2) micro- and ultramicroscopic granules, (3) amicrons and nondissociated mols., and (4) ions. When the suspension in case (1) is placed between the poles of a powerful electromagnet, the granules will be attracted and will move through the liquid toward the poles. Thus if to a dil. soln. of FeCl_3 a little K_2SO_4 is added the granules of $\text{Fe}(\text{OH})_3$ formed will not be attracted at first but when they have increased sufficiently in size a slight attraction occurs. In discussing case 2 it is imagined that the granules are spheres 1 mm. in radius. If these are reduced to 1μ in radius the surface is increased 1000 times and the movement of these particles will be much less in the same field. The relation of Stokes' law to this case is discussed; it is found to apply, from which it is found that the velocity of the 1 mm. particles is 1,000,000 times that of the 1μ particles. For particles with a radius of 10μ the velocity would be 10^{10} less than that of the 1 mm. particles. The same reasoning applies even more strongly to case 3 and a variation in the conc. when in the field is even less possible. In case 4 no variation in the conc. takes place under the influence of the field. The whole liquid undergoes either attraction to the poles or with the dil. soln. less than is exerted on the solvent alone. Thus the ions behave as though rigidly connected with the solvent. Disregarding the mols. of H_2O of hydration the ions are surrounded by an extensive layer of H_2O mols. which are turned with the oppositely charged face toward the ion and are held by electrostatic force. It is for this reason that a magnetic force acting on the individual Fe ions acts on the whole FeCl_3 soln. and placed in a magnetic field acts paramagnetically, but when filled with a nondissociated soln. of colloidal $\text{Fe}(\text{OH})_3$ the effect is absent.

E. J. WITZEMANN.

Catalysis. XIX. Reactions of both the ions and the molecules of acids, bases, and salts. Conductivity and ionization of sodium ethylate, potassium ethylate, lithium ethylate, sodium phenolate, potassium phenolate, sodium phenylthiouazole, sodium iodide, sodium bromide and mixtures of these electrolytes in absolute ethyl alcohol at 0, 25 and 35°. H. C. ROBERTSON, JR. AND S. F. ACREE. *J. Phys. Chem.* 19, 381-432 (1915); cf. *C. A.* 7, 3125.—Cells of dumb-bell shaped cross section, and other forms were used, the object of the constriction being to give the cell a greater resistance. In some of the cells the constricted portion was smaller than the electrodes. For cells of very small resistance, Pt cylinders of different sizes arranged on concentric axes were used. Solns. were prepared by vol. at 25° and corrected for vol. changes at 0 and 35°. Good commercial chemicals were used without purification for the expts., with the exception of EtOH and PhOH, which were distd. and dried. Temp. coeffs. of cond. were practically the same for all salts, 2.65% per degree from 0 to 25°, and 2.8% per degree from 0 to 35°. Duplicates generally agreed within 0.5%. Electrolytes in alc. cause a much larger increase in viscosity than the same salts in H_2O . The viscosities are additive for mixed electrolytes when the total conc. is not more than 0.5 *N*; at higher concs. the viscosities and conds. are smaller than the values calc. from the mixt. law. The cond. ratio without a viscosity correction gives a better value for the degree of dissociation than the ratio corrected for viscosity according to Noyes, Washburn, and others, though neither ratio gives a good value over 1.0 *N* concn.

E. B. MILLARD.

Relation between affinity constant and catalytic activity of an acid. H. S. TAYLOR. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 1, 9 pp.; cf. *C. A.* 8, 2096.—No formulation of the exact mechanism of catalytic hydrolysis can be given on account of the uncertainty as to the degree of dissociation of the catalyte. This is due to lack of knowledge as to corrections for viscosity and similar properties. A plot of $\log K_m : \log K_H$ against log affinity const. was drawn through the origin and was best shown by a straight line

most nearly dividing the points into 2 groups, rather than by a line convex toward the affinity const. axis and more or less asymptotic to it. The slope of this line was 0.5, or, $2 \log K_m : \log K_H = \log A.K.$ Then if c' is the conc. of the H ion and c is that of the undissociated mols., $K_m^2/K_H^2 = c'^2/c^2$. The results of Dawson and Powis (*C. A. 8*, 1373, 2293) in general confirm this conclusion though the relation $K_m : K_H = 0.1$ was not very close. D. and P.'s data show 0.5 for this relation. The strength of the acid is probably the detg. factor in this catalytic ratio, and deviations from the equations above are to be sought for in the variations of the nature of the reaction studied. As before, it was stated that the catalytic ratio varied somewhat with the reaction which was being catalyzed.

E. B. MILLARD.

Activity of the undissociated molecule in ester catalysis. EVA RAMSTEDT. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 7, 33 pp. (1915).—Detns. have been made of the degree of dissociation at different concns. of β -naphthalenesulfonic, trichlorobutyric, and cyanoacetic acids and H_3PO_4 and of their Na salts, by the conductivity method. The rate of hydrolysis of EtOAc by each of the acids at various concns., with and without the presence of the corresponding Na salt, has also been detd. The hydrolytic activity could be represented by the equation of Sneath and Taylor: $R = n_H K_H + n_m K_m$, where R was the reaction const., n_H and n_m were the concns. of the ion and the undissociated mol., and K_H and K_m their respective catalytic activities. By comparing the exptl. data for different concns. of acid, with and without salt, fairly concordant values of K_m and K_H were found for each acid, K_H being nearly equal for all acids and K_m always depending on the nature of the undissociated mol. The ratio $K_m : K_H$ was 0.98 for β -naphthalenesulfonic acid, 0.055 for trichlorobutyric, 0.003 for cyanoacetic and 0.01 for H_3PO_4 . Assuming (with Szyszkowski) that the increase of dissociation const. with concn. was due to the effect of the undissociated mol., it was shown that the effect was greater for larger values of the ratio above. This was considered important for the strong acids for which the simple rule that $K_m : K_H$ grows with the dissociation const. cannot be applied.

E. B. MILLARD.

The allotropy of cadmium. V. The heat of transformation: $Cd_\alpha \rightleftharpoons Cd_\gamma$. ERNST COHEN AND W. D. HELDERMAN. *Utrecht. Verslag Akad. Wetenschappen* 23, 1015-19 (1914).—It has already been pointed out in connection with the thermodynamics of normal Cd cells that this metal may exist in various allotropic modifications (cf. *C. A. 9*, 1267). In order to measure the heat of transformation of Cd_α to Cd_γ , cells containing each variety of Cd were made up according to the following plan: $Cd | CdSO_4 \text{ soln.} | Cd \text{ amalgam}$. Measurements of the e. m. f. (E) and the temp. coeff. of E for each cell were sufficient for the calcn. of the heat of transformation by means of the well-known Gibbs-von Helmholtz equation. It was thus found that 1 g. atom of Cd_α goes over at 18° into Cd_γ with an absorption of 739 g. cal. By extrapolation of the results the metastable inversion $Cd_\alpha \rightleftharpoons Cd_\gamma$ would appear to take place at 95° .

L. H. ADAMS.

Solubility curves of salt hydrates: calcium nitrate. H. S. TAYLOR AND W. N. HENDERSON. *J. Am. Chem. Soc.* 37, 1688-94 (1915); cf. Basset and Taylor, *C. A. 6*, 2044, and D'Ans and Siegler, *C. A. 7*, 2002.—The satd. solns. analyzed were prepared from supersatd. solns. by inoculation with a small crystal of $Ca(NO_3)_2 \cdot 4H_2O$ and then allowing the solns. to stand until equil. was attained at the desired temp. It was possible to obtain solid unstable $Ca(NO_3)_2 \cdot 4H_2O$ in equil. with the soln., and to show that the solid phase was the unstable hydrate by inoculation of the system with a small crystal of the stable hydrate, when more solid sepd. from the liquid phase. The results have been plotted with those of Basset and Taylor into the usual form of phase diagram. The solubility of the anhydrous salt at 25° agreed with that of B. and T. (l. c.) but not with that of D'Ans.

E. B. MILLARD.

Influence of temperature on the velocity of solution of magnesium in hydrochloric acid. W. BONDORFF. *Medd. K. Vetenskapsakad. Nobelinst.* 3, No. 8, 34 pp.(1915).—The velocity of the reaction was very small up to temps. of -20° ; it increased somewhat more rapidly then up to 20° , and from there up was nearly proportional to the temp. A sharp break in the velocity curve in the neighborhood of the f. p. of H_2O was not observed. The velocity of the reaction was also influenced by the concn. of the acid, this curve rising somewhat more rapidly than the concn. E. B. M.

Diffusion of gases through mercury vapor at low pressures, and the diffusion air pump. W. GADE. *Ann. Physik* 46, 357-92(1915).—For simultaneous diffusion of Hg and other gases from a flask (during exhaustion) the Stephan diffusion equation was confirmed. A pressure much lower than the pressure in the pump can be obtained in a flask by use of the pump if the tube between the vessel and the pump be cooled. When air-free H_2O vapor was maintained outside of a clay cylinder connected inside to a vessel, the pressure within the vessel dropped from 750 to 15 mm. when the H_2O was condensed at room temp. By combining this principle with a water pump, a Röntgen tube was exhausted until Röntgen rays were produced. E. B. MILLARD.

The diffusion coefficient of gases and the viscosity coefficient of gas mixtures. J. P. KUENEN. *Leiden. Verslag. K. Akad. Wetenschappen* 23, 1049-54(1915).—In this communication K. gives a further discussion of diffusion coeff. and viscosity coeff. of gases and mixts. (cf. C. A. 8, 1038, 2836). A slight mistake in K.'s former calcs. is pointed out and formulas are modified accordingly. L. H. A.

The influence of hydration and of the deviations from the ideal gas laws in aqueous solutions of salts on the freezing points and the boiling points. C. H. SLUTTER. *Verslag. Akad. Wetenschappen* 23, 920-30(1914); *Chem. Weekblad* 12, 178-208(1915).—The ionization coeff., i , of KCl, NaCl, $CaCl_2$, and $MgCl_2$, in aq. soln. was detd. at 0° and at 100° from cond. measurements at concns. varying from 0.0005 to 1.0 formula-wt. per 1000 g. H_2O . The values of i so obtained were compared with those derived from measurements of the f. p. lowering and b. p. increase, resp., for the same salts, at concs. from 0.01 to 1.0 formula-wt. per 1000 g. H_2O . The cond. detns. were carried out in the usual way, using a slide wire bridge, induction coil and telephone. The sp. cond. of the water used was 0.6×10^{-4} . The f. p. measurements were detd. by the method of Robertson and Walker, in which corrections for the influence of radiation and for other temp. effects are done away with. Temps. were measured with a Beckmann thermometer (nominal accuracy 0.001 $^{\circ}$). The b. p. detns. were obtained with an app. consisting of twin copper cylinders, one containing pure H_2O and the other the soln. under investigation. Simultaneous readings of the temps. in each were made by means of 2 Beckmann thermometers. The various results are compared with those of previous investigators and fair agreement found. The difference between the values of i obtained from cond. measurements on the one hand and from f. p. and b. p. detns. on the other hand are explained by S. by assuming (1) an increasing hydration of the salts in the following order: KCl, NaCl, $CaCl_2$, $MgCl_2$; (2) a decrease in hydration with rising temp.; (3) a deviation from the ideal-gas law for the osmotic pressure and therefore a deviation from Raoult's law for f. p. and b. p. changes. This is ascribed to the influence of the factors a and b in van der Waals' equation of state.

L. H. ADAMS.

Theoretical determination of the entropy-constant of gases and liquids. H. TETRODE. *Verslag. Akad. Wetenschappen* 23, 1110-27(1915).—From purely theoretical considerations T. develops a formula for detg. the entropy const. by calcn. of vapor pressure according to the methods of statistical mechanics. The next step is the application of these formulas to the calcn. of gas equilibria. T. concludes with a gen-

eral discussion of the significance of Boltzmann's conception of entropy in relation to various states of matter.

L. H. A.

Determinations of the ratio of specific heats of gases from the velocity of sound.

A. LÉVUC. *Compt. rend.* 160, 601-3(1915); cf. C. A. 9, 1870; *Ann. chim. phys.* [7] 17, 499.—Attention has been directed to 10 detns. of the ratio, in which gross errors have been made. By reversing the calcn., and computing the velocity of sound in these gases, values were obtained from 1250 m. per sec. for H to 481 m. per sec. for satd. H₂O vapor at 100° and 190 m. per sec. for satd. ether vapor at 22 cm. of Hg.

E. B. MILLARD.

The sol and gel state of gelatin solutions. I. Gelatinizing. II. Swelling. I. ARSZ. Koll. Beihefte 7, 1-90(1915).—A study was made of the viscosity of gelatin solns. at different temps. The gelatin used was purified by dialyzing in running H₂O for several days and then drying over H₂SO₄. It was dissolved at 50-60° in glycerol containing 32% H₂O. The viscosities were detd. with Ostwald viscosimeters. A battery of 7 viscosimeters were used so that the time could always be regulated to more than 2 min. The detns. were carried out in thermostats. It was found that a 10% soln. of gelatin maintained at 95° quickly decreased in viscosity. At 85° and 75° the viscosity decreased more slowly, while at 65° no change in viscosity could be noted after 24 hrs. From this it is seen that in gelatin solns. a chem. change takes place at high temps. which does not occur below 65°. This change is irreversible. Below 65° it was found that a gelatin soln. reaches an equil. which differs according to the temp. The equil. for a given temp. can be found by detg. the change in viscosity of 2 gelatin solns., one being cooled from a higher temp. and the other being warmed from a lower temp. The curves for the changes of viscosity will approach a point characteristic for that temp. and can be calcd. The changes in viscosity below 65° are reversible and are due to differences in inner compn., depending on whether or not the soln. has been agitated. At higher temps. the equil. is reached more quickly than at low temps. The relation between the Tyndall phenomenon and temp. was also studied (cf. C. A. 8, 1039). For the method reference must be made to the original. To compare the results with the above viscosity expts. solns. of gelatin in glycerol and H₂O were used. It was found that in a soln. which is cooled from 70° to room temp. the intensity of the dispersed light gradually increases. The gelatinizing of the soln. has no effect on the results. The intensity of the Tyndall phenomenon is dependent on the temp. at which the detn. is made and the thermal history of the soln. At higher temps. the results are high, while at lower temps. they are low. At const. temps. the intensity of the dispersed light increases or decreases according to the previous treatment of the soln. An equil. could be obtained only at higher temps. The results are explained as being due to the different sizes of the particles at different temps. The swelling of gelatin in H₂O was detd. by immersing sheets in H₂O kept at the required temp. in thermostats and detg. the increase in wt. from time to time. The rate of swelling of dry gelatin in H₂O is very rapid at high temps. so that the gelatin goes into soln. in a very short time. Below 30° the swelling is slower. The curves of swelling at 2° and 12° show that most of the swelling takes place during the first hour and that after that the increase in wt. is very slow; no equil. was reached even after 3 weeks. The rate of swelling depends on the thickness of the gelatin and also on its water content. In the case of gelatin containing water it was also found that the age of the gel has a great influence on the swelling. A freshly gelatinized 20% gel, at 20°, increased very much more quickly than the same gel which had been kept out of water for 3 days at 20° and then immersed in water at 20°. The same results were obtained at 10°. If a gel which is at equil. at 20° is cooled to 10° it takes up water faster than before. In the swelling of gelatin the water changes the size of the gelatin particles and probably decreases the attraction of the particles for each other.

Relation between "limiting value" and concentration of arsenic trisulfide sols. H. R. KRUYT AND J. VAN DER SPEK. *Verslag Akad. Wetenschappen* 23, 1104-9(1915).—Previous communications by K. and others (cf. *C. A.* 8, 543) have dealt with the limiting value of the amt. of various electrolytes which may be added to certain sols without causing flocculation. The present communication is an account of expts. on the flocculation of As_2S_3 sols of varying concn. by means of KCl, BaCl₂ and $KAl(SO_4)_2$. The As_2S_3 sols were prepd. by the method of Schulze, and varied in concn. between 5 and 75 g. per 1000 g. H_2O . It was found that the "limiting value" of K concn. was practically independent of the concn. of As_2S_3 , while those for Ba and Al were nearly proportional to As_2S_3 concns.; this value was much less for Al than for Ba and less for Ba than for K. L. H. ADAMS.

Mercuri-organic colloidal compounds. III. M. RAFFO AND G. ROSSI. Univ. Bologna. *Gazz. chim. ital.* 45, I, 132-9(1915).—In a preceding paper (*C. A.* 7, 1259, 1724) colloidal pentamercuriacetanilide was described. Colloidal tetramercuriacetanilide has also been obtained (cf. *C. A.* 8, 2775). Both of these compds. are formed in solns. contg. AcOH and the presence of AcOH is necessary for their colloidal stability. Expts. showed that there exists between the colloids tetra- and pentamercuriacetanilide and AcOH, which is formed with them, a peculiar elec. equil. completely analogous to that existing in solns. of colloidal S, between the colloid and the crystalloids H_2SO_4 and Na_2SO_4 ; it manifests itself by a diminution of the elec. cond. of the crystalloids of formation. Addition of a crystalloid capable of coagulating the colloid is accompanied by a decrease of the cond. due to the transference of elec. charges from the coagulating crystalloid and from the crystalloids of formation to the colloidal particles. E. J. WITZEMANN.

Some further experiments with liquid drops and globules. C. R. DARLING. *Proc. Phys. Soc. London* 26, 118-9(1914).—Several descriptive expts. P. D. F.

Transition from ordered to turbulent flow in capillary tubes. II and III. WALTHER SORKAU. Buenos Aires. *Physik. Z.* 16, 97-101, 101-2(1915); cf. *C. A.* 7, 435, 2001, 3559, 3695; 8, 2832; 9, 17.—Data for H_2O , benzyl alc., Me_2CO , $EtOAc$, and CCl_4 at several temps., and by using the app. previously described, have been taken. The results are shown in numerous diagrams. There is usually a sharp break from Hagen turbulence to the second type of turbulent flow. The critical velocity is detd. only by the diam. of the capillary tube. E. B. MILLARD.

Boundary film between a liquid and its saturated vapor. C. A. MEBIUS. *Physik. Z.* 16, 121-7(1915).—Theoretical. E. B. MILLARD.

Influence of time on the solidity of colophonium and colophonium-wax mixtures. F. HAUSER. *Verh. deut. physik. Ges.* 17, 95-103(1915).—During 70 days the pure substance and the wax mixt. remained unchanged, within the limits of the expts. The brittleness of pure colophonium decreases on standing, but that of the wax mixt. increases on account of the crystn. of the wax. Both materials exhibit a peculiar behavior on standing for a long time in H_2O , but no explanation was offered for it. E. B. M.

Organic liquids and alkaline solutions. T. J. TWOMEY. *J. Phys. Chem.* 19, 360-2(1915).—Drops of $CHCl_3$ or CCl_4 when allowed to fall into H_2O or H_2SO_4 were spherical and coalesced easily. If added to NaOH or if the H_2SO_4 was made alk., the drops flattened and did not coalesce easily. Air bubbles formed on the drops, apparently because air was drawn from the soln. by the organic liquid. No explanation of the effect is offered. E. B. MILLARD.

Velocity of crystallization from aqueous solutions. N. P. CAMPBELL. Kandy, Ceylon. *J. Chem. Soc.* 107, 475-80(1915).—The method employed was to hang in a slightly supersatd. soln. of K alum 2 weighed crystals of alum as nearly perfect as possi-

ble. The soln. was stirred while the temp. fell slowly, and the crystals grew regularly and rapidly. No attempt was made to regulate the temp. other than to take advantage of the difference between day and night temps. to produce supersatn. The crystals did not grow according to the law $m = kt$ (m = mass of crystal and t = time), as found by Richards and Archibald for small crystals growing in highly supersatd. solns. (*Am. Chem. J.* 26, 61(1901)), but according to the results of these expts, $m^{1/3} = kt$. Addition of portland cement to the alum soln. caused complete suppression of the octahedral faces, and the appearance of cubic crystals which grew as rapidly as the octahedral crystals. When these cubes were recrystd. from H_2O they assumed again the octahedral form. In a soln. supersatd. with both alum and $K_2Cr_2O_7$, an alum crystal and one of $K_2Cr_2O_7$ grew side by side with perfect faces. E. B. MILLARD.

Anomaly of the viscosity coefficients of anisotropic liquids. R. SCHACHENMEIER.
Ann. Physik 46, 569-76(1915).—Mathematical. E. B. MILLARD.

Molecular resistance encountered by a plate moving in gas. MARTIN KNUTSEN.
Översigt K. Vidensk. Selsk. Forh. 1914, 311-27; *Ann. Physik* 46, 641-56(1915).—After a theoretical calcn., expts. were performed upon two moving plates, one moving at right angles to the plane of rotation, the other moving parallel to the plane. By first measuring the angle of rotation in a vacuum and then in various gases, it was found that the exptl. numbers corresponded closely with the theoretical. P. M. GLASOR.

Measurement of very low temperatures. XXIII. The vapor pressure of hydrogen from the boiling point down to near the triple point. H. KAMMERLINGH ONNES and W. H. KERSOM. *Proc. Akad. Wetenschappen Amsterdam* 16, 440-5.—Discrepancy between the heat of vaporization of H at the b. p. found by expt. and by calcn. from the Clapeyron-Clausius equation led to a repetition of the exptl. work on the part of the authors. Temps. were measured by a Pt resistance thermometer recently compared with a H thermometer. Observations covered the range -252.63° to -258.31° and extrapolation over 0.80° on the calibration of the Pt resistance thermometer gave -259.14° as the triple p. with a pressure of 5.07 cm. Observations with much and little liquid corresponded to a temp. interval of 0.003° , well within the limits of exptl. error. The triple p. was read from the temp. of the bath when the first crystals became visible in it. The curve which represents $\log p$ as a function of $1/T$ is slightly concave upwards, thus differing from that of Travers and Jaquerod (*Trans. Roy. Soc. London (A)* 200, 155(1902)), which is slightly convex upwards. The b. p. was found to be -252.76° . This agrees with that found by Travers and Jaquerod (*loc. cit.*). The heat of vaporization of H at a pressure of 75.15 cm. from the Clapeyron-Clausius equation gives 105.5 cal. while that found by the direct measurement above at the smallest velocity of vaporization gave 110.2 cal. This high result may be due to the condensation of vaporized H within the calorimeter. It agrees essentially with Onnes' previous result. J. W. SHIPLEY.

The ice calorimeter. With remarks on the constancy of the density of ice. EZER GRIFFITHS. Univ. Wales. *Proc. Phys. Soc. London* 26, 1-14(1913). Discussion. *Ibid* 14-5.—The mean value of the Bunsen calorimeter const. was found to be 15.486 mg. Hg per mean cal., i. e., mass of Hg drawn into the instrument by addition of 1 mean cal. Errors due to progressive freezing or thawing of the ice mantle were greatly diminished by suspending the calorimeter within a transparent vacuum vessel of cylindrical form, the stem and capillary of the calorimeter projecting through a rubber stopper, and the vacuum vessel being completely embedded in powdered ice. Various observers have found that the density of ice at 0° is not const. A consideration of their work leads to the conclusion that the small variations observed may be due to occluded water or an amorphous modification cementing the ice crystals together. The value

of the latent heat fusion (80.30) calc. from the calorimeter const. supports this view, as it is higher by about 0.7% than the value obtained by direct detns. with ice in bulk.

PAUL D. FOOTE.

The thermal expansion of mercury and fused silica. F. J. HARLOW. *Cass Tech. Inst. Proc. Phys. Soc. London* 26, 85-94(1914). Discussion. *Ibid* 94-6.—Fused silica bulbs containing Hg were heated in an oil bath and the overflow of Hg weighed. The following values were obtained for the differential expansion coeff. ($\times 10^6$) of Hg in silica: From 0° to 30, 50, 75, 100, 140, 184, 200, 250, 300°: 18060, 18068, 18081, 18102, 18150, 18220, 18248, 18356, 18489, resp. The linear coeffs. ($\times 10^6$) of expansion of silica detd. by Callendar for above temp. ranges are as follows: 35.8, 39.6, 43.4, 46.6, 50.5, 53.9, 54.9, 57.6, 59.8. Expt. shows that silica is isotropic; hence cubical expansion is 3 times linear expansion. Using Callendar's values, the abs. coeffs. ($\times 10^6$) of expansion of Hg for the above temp. ranges are: 18168, 18188, 18213, 18244, 18305, 18387, 18419, 18537, 18678, resp. These results differ from detns. by the abs. method by other observers. Sears, in discussion, gives a recomputed table of Harlow's values for Hg based on expansion of silica detd. by other investigators.

PAUL D. FOOTE.

Relation between temperature coefficient of expansion of solid substances and the temperature. S. VALENTINER AND J. WALLOT. *Ann. Physik* 46, 837-67(1915); cf. *C. A.* 9, 12.—Detns. have been made over the temp. range from 0° to liquid air or liquid H temps. on the coeff. of temp. expansion of quartz glass, invar, Pt, Ir, Rh, CaF₂, and pyrite, and the results have been discussed in the light of the Nernst-Lindemann formula for sp. heats of solid substances. The temp. coeffs. of the substances bear a relation to temp. similar to the N.-L. formula for sp. heat, and the former may be calcd. from the latter with an error of $\pm 1\%$. The relation could also be expressed as $\log \alpha_{T_1} - \log \alpha_{T_2} = \log \varphi(\beta v/T_1) - \log \varphi(\beta v/T_2)$.

E. B. MILLARD.

Relation between the physical quantities c , β , δ , and E for solid elements. J. KLEBER. *Ann. Physik* 46, 1054-6(1915).—The relation was obtained by eliminating v from the equations $v = 57.698 (c/\beta)^{1/2} - 637$ and $v = 99.04 (E/\delta)^{1/2}$. E was the modulus of elasticity of the element, δ its density, c its sp. heat, β the linear coeff. of expansion and v the velocity of sound in the substance.

E. B. MILLARD.

Investigations on the temperature-coefficients of the free surface-energy of liquids between -80° and 1650°. VII. The specific surface-energy of the molten halides of the alkali metals. F. M. JAEGER. *Groningen. Verslag Akad. Wetenschappen* 23, 611-27(1914).—The surface tension of a number of molten salts of the alkali metals was detd. with the same app. which has been previously used for other liquids (cf. *C. A.* 9, 738). The necessary measurements of the d. of the various salts as a function of temp. required for the calcn. of the molar surface-energy have not yet been completed and will be published later. The variation with temp. of the specific surface-energy in ergs/cm². (χ_t) of all the salts may be represented by the expression $\chi_t = a - b(t - t_s) + c(t - t_s)^2$ in which t_s is the m. p. and a , b and c are constants. The values of t_s , a , b and c , resp., of the various salts are as follows: LiF, 840, 255.2, 0.126, 0; LiCl, 608, 140.2, 0.076, 0; NaF, 990, 201.6, 0.106, 0; NaCl, 801, 114.1, 0.071, 0; NaBr, 768, 106.5, 0.069, 0; NaI, 660, 88.2, 0.053, 0; KF, 858, 143.2, 0.087, 0; KCl, 780, 97.4, 0.072, 0; KBr, 734, 88.8, 0.070, 0; KI, 681, 78.3, 0.064, 0; RbF, 765, 132.0, 0.131, 0.00012; RbCl, 720, 98.3, 0.086, 0; RbBr, 685, 90.7, 0.069, 0; RbI, 642, 80.3, 0.065, 0; CsF, 692, 107.1, 0.088, 0.0004; CsCl, 646, 91.3, 0.077, 0; CsBr, 631, 83.6, 0.063, 0; CsI, 620, 91.6, 0.056, 0. From these results it is apparent that χ_t as a function of t is very nearly a straight line in all cases. This result may be contrasted with the previous measurements in organic liquids for which the curvature of the χ graph is usually quite marked. The following conclusions are drawn from the observations:

(1) in the case of the four halides of the same alkali metal the temp. coeff. b of χ decreases continually with increasing at. wt. of the halogen atom; (2) at the same temp. the value of χ for the same halide of all the alkali metals decreases gradually with increasing at. wt. of the alkali metal; at the same temp. χ for the four halides of the same alkali metal gradually decreases with increasing at. wt. of the halogen atom. The relations, however, do not possess a simple additive character. Finally, reasons are given for believing that the liquid Li salts possess a higher degree of molar complexity than the salts of the other alkali metals. VIII. The specific surface energy of various salts of the alkali metals. *Ibid* 627-40.—The results for these salts expressed as above in terms of t_s , a , b and c , resp., are as follows: Li_2SO_4 , 852, 224.4, 0.067, 0; Na_2SO_4 , 884, 196.3, 0.140, 0.00042; K_2SO_4 , 1074, 144.5, 0.066, 0; Rb_2SO_4 , 1055, 135.0, 0.087, 0.00007; Cs_2SO_4 , 1015, 113.1, 0.087, 0.00006; LiNO_3 , 254, 118.4, 0.063, 0; NaNO_3 , 312, 120.7, 0.063, 0; KNO_3 , 339, 112.9, 0.075, 0; RbNO_3 , 304, 109.4, 0.075, 0; CsNO_3 , 414, 92.0, 0.084, 0; LiBO_2 , 845, 264.8, 0.082, 0; NaBO_2 , 965, 201.6, 0.159, 0; KBO_2 , 964, 136.6, 0.310, 0.00053; Na_2MoO_4 , 687, 215.1, 0.121, 0.00009; K_2MoO_4 , 919, 152.5, 0.066, 0; Na_2WO_4 , 694, 204.4, 0.068, 0; K_2WO_4 , 921, 158.2, 0.083, 0; NaPO_3 , 620, 2095, 0.059, 0; KPO_3 , 820, 161.2, 0.069, 0 (up to 1275°). In all cases except the last the max. temp. reached was 1500-1600°. Inspection of these results shows that in most cases χ decreases with increasing at. wt. of the metal. L. H. ADAMS.

Surface tensions of water, methyl, ethyl and isobutyl alcohols, ethyl butyrate, benzene and toluene. T. W. RICHARDS AND L. B. COOMBS. *J. Am. Chem. Soc.* 37, 1656-76(1915).—The capillary tubes were carefully tested for uniformity of bore by measuring a Hg thread in different portions; only tubes in which the length of the thread varied less than 1 part in 2000 were used. Height of meniscus was read by means of a black shield held tangent to the meniscus. It was shown that when a fine glass rod was immersed in H_2O in the middle of a tube 20 mm. in diam., there was a "capillary" rise of 0.31 mm.; this was offered as the explanation of the wide differences between the detns. of surface tension by various workers with this method. In the app. here used the capillary did not dip into the liquid in the middle of another tube, but formed one arm of a U-tube, the other arm of which was a tube 38 mm. in diam. It is shown that at least this diam. is required if a flat surface is obtained in the middle of the tube. The limbs of this tube were fused to a stopcock which served to close both of them. The position of each meniscus was read with the app. in 4 different positions to eliminate errors from prismatic irregularities in the glass walls of the tubes. The surface tensions found were H_2O 72.62 dynes per cm. at 20°, C_6H_6 28.91, toluene 28.58, MeOH 22.61, EtOH 22.27, iso-BuOH 22.85, and Et butyrate 24.54. This preliminary work is to be followed by further data. E. B. MILLARD.

An experiment with the ion theory. F. SCRIBA. Darmstadt. *Z. physik. chem. Unterr.* 28, 94-5(1915).—A glass test tube about 1 in. diam. and 8 in. long has 2 electrodes fused in near the bottom, is half filled with pure H_2O and held in a clamp. A smaller tube with a small hole in the lower end passes through a cork and dips in the H_2O . The electrodes and a block of pure, dry rock salt held between 2 springs are connected in parallel with a d. c. of 110 v., an incandescent lamp being inserted beyond the connection. The lamp does not glow until a bit of the salt is dropped into the inner tube and begins to dissolve. J. H. MOORE.

Experiments with very strong thermoelectric currents. W. VOLKMANN. *Verh. deut. physik. Ges.* 17, 72(1915).—The heat from a Bunsen burner was sufficient to give rise to a current which operated an electromagnet of 10 kg. pulling force. By using a blast lamp, a current of 150 amp. could be generated. Details were not given. E. B. MILLARD.

Potential of silver against silver ion in concentrated solutions of potassium and of sodium chloride, and its relation to the activities of such solutions. G. S. FORBES AND F. O. ANDEREGG. *J. Am. Chem. Soc.* 37, 1676-85(1915).—Potentials have been measured at 25° for cells of the type Ag | dil. AgNO₃ | KNO₃ | AgCl in conc. MCl | Ag, where MCl was either NaCl or KCl at concns. between 0.38 and 3.9 N. Diffusion potentials were eliminated by the use of conc. KNO₃ in agar-agar. From the data, values of the activity of chloride ion have been calcd. The activity of chloride ion in relation to concn. decreases as concn. increases from small values up to 1.7 N, and the minima attained (0.385 and 0.394) are almost identical for both chlorides. These minima are not due to a decrease in the solubility product of AgCl but to a change of the Ag complex from M₂AgCl₂ to M₃AgCl₄. The solubility product of AgCl was assumed const., and evidence offered to show that its variation does not greatly affect the conclusions. The activities obtained by this method are always smaller than those from conds. except in the more conc. solns. of NaCl. The dissociation calcd. from them reaches a minimum at 1.7 N.

E. B. MILLARD.

The influence of organic bases on the potential of the hydrogen electrode. ARRIGO MAZZUCHELLI. *Univ. Rome. Atti accad. Lincei* 24, I, 139-43(1915).—The bases used were quinine, cinchonine, brucine, veratrine, coniine, hydrastinine, quinoline, lutidine, dimethylaniline, and phenylhydrazine as the sulfates. As was observed in the case of Zn, the addition of these bases make the potential of the H more nearly that of the noble metals. Quinoline and dimethylaniline have an especially strong effect as in the case of Zn. PhNHNH₂ probably acts as a depolarizer. Gelatin, saponin and starch have no effect.

E. J. WITZEMANN.

The electrical conductivity and fluidity of strong solutions. W. S. TUCKER. *Proc. Phys. Soc. London* 25, 111-24(1913).—Cond. and viscosity of CaCl₂ solns. were measured isothermally and at varying concns. for several different temps. Expressing concn. as the ratio of masses instead of by vol. (mols. solute per 100 mols. solvent) the relation between conc. and ratio of cond. to fluidity is linear except at low concn. The rate of decrease of cond. with decreasing temp. decreases.

PAUL D. FOOTE.

Influence of pressure on the electrical conductivity of pure metals according to a theory of E. Grüneisen. BENGT BECKMANN. *Physik. Z.* 16, 59-62(1915).—Grüneisen's equation for the elec. cond. of a metal as a function of its compressibility gives the correct order of magnitude for the pressure function, with the exception of Hg and Bi. It holds rigorously for Au, Ag, Cu and Al, and is to be considered as an approximation for all other metals.

E. B. MILLARD.

Influence of temperature and pressure on the electrical conductivity of palladium during occlusion of hydrogen. B. BECKMANN. *Ann. Physik* 46, 481-502(1915).—The first 30 vols. of H per vol. of Pd increase the resistance very greatly; from this to 925 vols. the ratio of resistance to initial resistance was $W'/W = a + bv$, where $a = 1.0292$ and $b = 0.000668$. Above 925 vols. of H the resistance increases more slowly and supersatn. has no effect. The cond. at 18° was almost a linear function of the at. % H; the pressure coeff. of resistance was also a linear function of the atomic % H.

E. B. MILLARD.

Influence of pressure on the electrical conductivity of tellurium. BENGT BECKMANN. *Ann. Physik* 46, 931-40(1915).—Te was melted into a capillary and there cooled. Pt wires fused into the ends of these Te wires served as electrodes. The expts. have been made on the resistance at 0° for pressures from 250 to 1500 atm. on several specimens. A plot between pressure coeff. and resistance at 0° was nearly a straight line. The resistance could be expressed as an exponential of the pressure.

Considerable variation between the various specimens was found; this complicated general treatment.

E. B. MILLARD.

Nature of electrical conduction as required to explain the recovery of resistance of metallic selenium following illumination. F. C. BROWN. *Phys. Rev.* [2] 5, 395-403(1915); cf. *C. A.* 9, 1424, 1427-8.—Assuming that the specific cond. varies as the number of electrons taking part in the conduction at that instant, that the electrons do not exist free in the sense of the kinetic theory of gases, but that under illumination they are rendered free (or unstable), and that the recombination of the freed electrons will take place according to the law governing the recombination of ions in gases, the rate of recombination may be expressed as $dN/dt = -aN^2$, where N is the av. number of electrons in the free state at any instant and a is the coeff. of recombination. Then if $i = kN$, $di/dt = -a'i^2$. The approx. form of the equation, $\Delta i/\Delta t = -a'i^2$ was verified, not the integrated form, since in the latter case when a large % of the electrons have combined, a non-uniform distribution of them causes a decrease in the coeff. of recombination. The value of a' was approx. const. for 0.05 sec. period of recovery. The coeff. of combination under different pressures varies inversely as the cond. ensuing from the pressure, and the evidence points to the view that the rate of production of electrons by light falling on Se varies directly as the same cond. resulting from the pressure effect. The coeff. of recombination varies with the potentials applied in such a way as to explain the deviations from Ohm's law. The voltage effect is thus identical with the pressure effect.

E. B. MILLARD.

Ionization. J. J. THOMSON. *Proc. Phys. Soc. London* 27, 94-117(1914).—Ionization is the process by which ions (particles charged with electricity) are produced in a solid, liquid, or gas. This paper considers ions in gases in regard to (1) the nature of the ions, (2) the process by which they are produced. The evidence as to the nature of ions is derived from expts. on their mobility which have shown: (a) The mobility of a positive ion depends only on the gas through which the ions are moving and not on the nature of the gas out of which the ions are formed. (b) The mobility of the ions in a gas at const. d. is independent of the temp. (c) There is a considerable number of gases in which the mobility is very approx. inversely proportional to the sq. root of the d. of the gas. (d) In the case of negative ions there is an abnormal increase of mobility when the pressure is reduced below a certain value, and there is some evidence that this is also the case for + ions at very low pressures. Two theories of the mobilities of ions are considered, one founded on the view that the action between ions and mols. is analogous to impacts between hard elastic spheres, the other on Maxwell's theory of forces between ions and mols. varying inversely as the 5th power of the distance between them. (a) follows from the 2nd theory provided the ion is a cluster whose mass is considerably greater than that of a mol. of the gas through which it is moving. It follows also from the 1st theory if all ions in a given gas are the same size. (b) follows at once from the 2nd theory; to explain it on the 1st theory requires that the size of the ion vary with the temp. in a definite manner. The necessary relation can be deduced from thermodynamical reasoning under certain assumptions. (c) requires on the 1st theory that the ions in these gases be the same size, on the 2nd theory that the gas mols. exert the same force on a charged point at a given distance. (d) follows on either theory if the ion dissociates at low pressures so that free corpuscles are present in the gas. The 1st stage of the process of ionization in the vast majority of cases consists in the detachment of an electron or corpuscle. Evidence as to the method by which this takes place is afforded by detns. of the velocity with which the electrons are ejected from the body. In the case of ionization by light or Röntgen rays this velocity depends primarily on the wave length of the radiation, not upon its intensity, nor on the nature of the mol. from which the corpuscle is ejected. This

velocity is far greater even when every allowance is made for resonance than can be accounted for if it is supposed that the energy of the light is uniformly distributed, and that the corpuscle acquires its velocity by the action on it of the elec. force in the wave. Another explanation not open to these objections is advanced. When ionization is due to the action of moving electrified particles, whether + or —, the results are quite different. The velocity of the ejected particles (δ rays) does not seem to vary much with the velocity of the particles which eject them, and is of the same order whether these particles are positive rays or the much swifter cathode rays. The method of ejection by the impact is considered, and suggestions given as to a possible theory and its consequences.—[AUTHOR'S ABST.]

PAUL D. FOOTE.

A lecture experiment to illustrate ionization by collision and to show thermoluminescence. F. J. HARLOW. *Cass Tech. Inst. Proc. Phys. Soc. London* 26, 55-9 (1913).—(1) A method is described for demonstrating to an audience ionization by collision and the reduction of the sparking potential by the presence of initial ionization. (2) CaO and AlPO_4 upon Pt, subjected while cold to an intense spark discharge, exhibit thermoluminescence, the CaO on being warmed giving out a golden yellow glow and AlPO_4 a blue glow. CaO on Ni or Al shows thermoluminescence but no effect was found for CaO on Cu. It seems probable that this phenomenon is connected with the elec. activity of salts and oxides upon metals.

PAUL D. FOOTE.

Force acting on the cathode during glow discharge. FRANK TUCZEK. *Physik. Z.* 16, 102-4 (1915).—The force exerted on the cathode during a glow discharge and its relation to the gas pressure over a range from 0.02 to several mm. of Hg has been measured with a rotating radiometer wheel and a torsion balance. The greater part of the force is due to thermoradiometric action which in turn is due wholly or partly to an electrostatic attraction. Its variations follow essentially those of the electrode potential. The relation of the force to current strength is complicated by a decided hysteresis; the curve shows breaks that are caused by forcing the negative glow through the wire net anode.

E. B. MILLARD.

Electron emission of a calcium oxide electrode in vacuum. WERNER GERMERSHAUSEN. *Leipsig. Physik. Z.* 16, 104-8 (1915).—In contradiction to the theory that a Wehnelt electrode could be active only by giving up gases and gradually exhausting the oxide film (on account of chem. reactions taking place in it), it was shown that the decrease of activity of a CaO electrode was caused by the residual gases just as with a W electrode. If a CaO electrode can act only by giving up gases, it should show (if the current has not risen to the impact-ionization value) a specifically smaller effect than a metal in a vacuum free from residual gases. By eliminating the residual gases from a CaO electrode, the const. b of the Richardson equation was considerably lowered, i. e., the electron emission was increased, and an effect obtained which was independent of the duration of the bombardment.

E. B. MILLARD.

Effects of different gases on the electron emission from glowing solids. FRANK HORTON. *Proc. Roy. Soc. London (A)* 91, 322-37 (1915); cf. *C. A.* 8, 3392.—The emission of electrons from lime or from a glowing Nernst filament is independent of the nature of the gas in the discharge tube, at least for air, O, N, and H. At low pressures the thermionic current from a given cathode under definite conditions was practically identical in all 4 gases. At higher pressures the thermionic currents vary, but an increased thermionic current does not necessarily mean an increased electron emission from the cathode; the large currents which are obtained at certain gas pressures, particularly with H, are the result of ionization of the gas mols. by collisions. O and H differ widely in their affinity for the material of an oxide cathode, so that the equality of the electron emission in these gases is evidence that the electrons are not produced by chem. action between the cathode and the surrounding gas. A Pt cathode produces

a genuine increase in the emission which appears to be brought about by the absorption of H by Pt. The exact manner in which the H acts is at present unknown, but Wilson (1908) has shown that the expts. can be explained on the supposition that the H atoms in the surface layer of the Pt are positively charged, and have the effect of lessening the work which an electron must do in order to escape from the metal. With an electrode like lime, or a Nernst filament, by which the H is not absorbed, the electron emission is unaltered by the presence of this gas. E. B. MILLARD.

Changes of mass of small mercury drops held in suspension in a gas. A. SCHIDLOF AND A. KARPOWICZ. *Physik. Z.* 16, 42-5(1915); cf. *C. A.* 8, 3141.—Droplets held between the plates of a condenser and made to move up and down were observed to have a gradually increasing time of rise and fall for a given distance. It was shown that the droplets were pure Hg, and that no other explanation could be found than a decrease in mass of the drops. E. B. MILLARD.

Derivation of the Planck-Einstein energy formula without the use of the quantum hypothesis. S. RATNOWSKY. Zürich. *Verh. deut. physik. Ges.* 17, 64-8(1915). E. B. MILLARD.

Light intensities of spectrographs and monochromatics. W. VOLEMANN. *Verh. deut. physik. Ges.* 17, 69-72(1915). E. B. MILLARD.

The principle of Hamilton in Einstein's theory of gravity. H. A. LORENTZ. *Verslag K. Akad. Wetenschappen* 23, 1073-89(1915).—Wholly mathematical. L. H. ADAMS.

The continuous spectra of gases. E. P. LEWIS. Univ. California. *Nature* 95, 394-5(1915); *Science* 41, 947-8(1915).—In photographs of the H spectrum obtained with a large two-prism spectrograph the continuous spectrum was frequently observed, extending in the ultraviolet to wave length of about 2100. The spectrum appeared to be uniformly continuous, and it is considered that its gradual fading out in approaching the wave length 2100 is due rather to the absorption of the thick quartz system than to the lack of these wave lengths in the emitted light. If the assumption is correct that the continuous spectrum is due to mol. collisions, then the number of collisions would depend mostly on the mean velocity of the mols. so that the number of collisions would rapidly diminish as the mol. wt. increases. This was found to hold true for H, He and Ne. With a 2 min. exposure the continuous spectrum of H was very intense, that of He about $\frac{1}{2}$ as strong, and that of Ne about $\frac{1}{3}$ as strong. N, Kr and Xe did not show any continuous spectra. It is pointed out that H tubes used in the way described may render excellent service as sources for the study of absorption spectra in the ultraviolet. W. H. ROSS.

The arc spectrum of gold referred to the international normals. MARIE QUINCKE. Bonn. *Z. wiss. Phot.* 14, 249-62(1915).—Using a concave grating, 6.5 m. radius, 20,000 lines per inch, dispersion in 2nd order 1 Å. per mm., C arc with Au in crater, 120 v., 5-6 amp., arc gap 6 mm., the arc spectra of Au and principle impurities were photographed and measured in the region $\lambda = 6700$ to 2300. Tables of intensity and comparison with data from other sources are given. PAUL D. FOOTE.

Measurements on the arc spectrum of manganese referred to the international normals. HANS FUCHS. Bonn. *Z. wiss. Phot.* 14, 239-48, 263-80(1915).—Using a Rowland concave grating, 6.34 m. radius, 20,000 lines per in., C arc with the + electrode bored out and filled with metallic Mn, 220 v., 6-10 amp., the arc spectrum of Mn was measured from 7070 to 2290. About 1200 lines are tabulated with intensities and detns. by other investigators. PAUL D. FOOTE.

Wave-number system of ruthenium. EMIL PAULSON. *Physik. Z.* 16, 81-4

(1915); cf. *C. A.* 9, 1426.—A table of 548 lines of Ru is shown. The lines consist of 65 groups of 18 lines each following each other at intervals. E. B. MILLARD.

Theory of the glow discharge. III, IV and V. RAGNAR HOLM. *Physik. Z.* 15, 782-3(1914); 16, 20-30, 70-81(1915); cf. *C. A.* 8, 1696. E. B. MILLARD.

Spectrum of gadolinium. E. PAULSON. Lund. *Physik. Z.* 16, 7-8(1915); cf. *C. A.* 9, 1426.—From Kayser's data, some regularities are found, a group of lines being repeated at intervals. E. B. MILLARD.

Criticism of the conception of an elementary quantum of electricity. (Analogous behavior of oil and metal particles in relation to electric charges and Brownian movement.) FRITZ ZERNER. Vienna. *Physik. Z.* 16, 10-3(1915).—A critical review. E. B. MILLARD.

Regularities in the platinum spectrum. EMIL PAULSON. *Ann. Physik* 46, 698-704(1915); cf. Kayser, *Abhandl. Berl. Akad.* 1897; *C. A.* 9, 1426.—Wave lengths are given for 175 lines, which belong to a group of 10 lines repeated 34 times. The strong line $\lambda = 3638.956$ must be double, for it comes in the 6th place in group 6 and the 3rd place in group 11. It fits equally well in both places. E. B. MILLARD.

Determinations of the active wave lengths of color filters. M. PIRANI AND W. W. LOEBE. *Verh. deut. physik. Ges.* 17, 47-62(1915); cf. *C. A.* 8, 3.—Expts. were made with a König spectrophotometer. Filters were "monochromatic" when, on moving 50μ from the max. permeability, the intensity of the transmitted light was 1% of that at the max. The calcd. max. agreed with the observed within 0.5%, except when the filter was near the limits of the visible spectrum. The best results were obtained in yellow-green light, which was accordingly stated to be the best for photopyrometric work. When a filter had several sharply defined maxima and minima, the max. permeability could be detd. only when the intensity at the highest max. was 10 times as great as at the nearest inferior max. When 2 maxima of about equal height are sepd. by a deep minimum, no effective max. can be detd. E. B. MILLARD.

Emission conditions for some band spectra of nitrogen and carbon. R. SEELIGER. *Physik. Z.* 16, 55-9(1915); cf. *C. A.* 8, 862. E. B. MILLARD.

Absorption spectra of various halogen derivatives of benzene and toluene as vapors and in solution. J. E. PURVIS. *J. Chem. Soc.* 107, 496-509(1915); *C. A.* 7, 564, 2215, 2348, 3444.—The considerable number of bands of *p*-C₆H₄Cl₂, *p*-C₆H₄Br₂, and of *o*-, *m*- and *p*-C₆H₄ClBr disappear in soln. and are replaced by a few moderately wide diffuse bands. There are differences between *o*- and *m*-comps. as compared with *p*-comps. which are more marked in the vapors than in soln. The marked absence of narrow vapor bands in phenylacetonitrile, BzCl and BzOH, the complete elimination of both vapor and soln. bands in *cyclo*-C₆H₄Cl₂, C₆Cl₆ and C₆Me₆, and the similarity of the vapor bands and soln. bands at higher temps. and pressures of comps. which exhibit a series of finer vapor bands at lower temps. and pressures are the remarkable features of the present expts. In soln. the solvent modifies the oscillations within the mol. so that on account of its external influence the number of individual bands is greatly decreased. A group of vapor bands seems to close up under the influence of the solvent to form a diffuse wide band, whereas in other instances the vapor bands are so weak that they practically disappear when the substance is in soln.

E. B. M.

Some temperature coefficients of refraction of optical glasses. J. W. GIFFORD. *Proc. Roy. Soc. London (A)* 91, 319-21(1915).—Data has been taken for 34 kinds of glass. E. B. MILLARD.

Part played by gases in the photoelectric behavior of zinc. HANS KÜSTNER. *Ann. Physik* 46, 893-930(1915).—Pure Zn, in the absence of active gases, gave no measurable photoelectric effect (see *C. A.* 8, 1382). A strong photoelec. effect was observable in presence of an active gas when the pressure was as great as 5×10^{-7} mm. of Hg, but no effect was produced by several thousand times this pressure of an inert gas. This behavior is in contradiction to the dielectric const. theory, according to which the effect should be zero only in an absolute vacuum. Also in contradiction to this theory was the fact that the photoelec. effect on a freshly cleaned surface did not appear until the pressure of H was raised to 16 times its previous value. Fatigue and recovery were both independent of the illumination over a wide range of currents.

E. B. MILLARD.

Photometry of vari-colored light sources. M. v. PIRANI. *Z. Beleuchtungsw.* 21, 41(1915).—An improved method is described.

C. G. F.

Diffusion and absorption of hydrogen in quartz glass. HERMANN WÜSTNER. *Ann. Physik* 46, 1095-1127(1915).—At 1000° and 3 atm., 0.06 cc. of H were taken up by the quartz surface, at 100° and 3 atm. only 0.0178 cc., and at 1100° 0.0342 cc., in 5 hrs. The absorption of H in quartz at 700 to 1000° was of the same order as the absorption of H_2O at room temp. At 1000° and 900 atm. the amt. of N taken up by quartz was only 0.003 cc. The expts. with O were abandoned because the hot O reacted with the Hg seals. It was not shown that the small amt. of N was not really a trace of O in the N being absorbed by the Hg. At the end of the O expt. nearly all of the O had combined with the Hg.

E. B. MILLARD.

Dispersion of electric double refraction. NIKOLAUS LYON. *Ann. Physik* 46, 753-84(1915).—The Kerr const. for CS_2 at 20° has been measured for 10 wave lengths distributed rather evenly between 460 and 670μ , with the mean value 1.13×10^{-11} and a probable error of about 4%. The dispersion of electrical double refraction was measured for several organic liquids by comparison with the CS_2 values. Values calcd. from the Havelock formula agreed with the exptl. values for substances with a large optical dispersion, but for Et_2O with its small elec. double refraction and weak optical dispersion the agreement was very rough.

Theory of radiation. W. WIEN. *Ann. Physik* 46, 749-52(1915).—Theoretical.

E. B. MILLARD.

Result of plotting the separation of homologous pairs (of spectrum lines) against atomic numbers instead of atomic weights. H. E. IVES AND OTTO STUELMANN, JR. *Phys. Rev.* [2] 5, 368-72(1915).—The discrepancies between the linear relation of log. at. wt. to log. of the distance between the lines of a spectroscopic pair as found by Runge and Precht (*Phil. Mag.* 5, 476(1903)) form the basis of the discussion. If atomic numbers are plotted instead of at. wts. the source of the "unknown disturbing cause" of R. and P. is found to be the use of (non-significant) at. wts. of B and K in place of at. numbers. K and B fall on the straight line of the plot then, in place of being "exceptions." The discrepancy between the chem. at. wt. of Ra and that found by the calcns. of R. and P. was 13%. In the present method this discrepancy was reduced to 8%, i. e., the calc. at. number was 96, and the true number is 88; but Mg has been the cause of a fresh deviation. At any rate the relation between at. number and line sepn. is satisfactory enough to suggest a review of the exptl. work on the Mg-Ra group. The work is considered as further evidence in support of the theory of a nucleus atom.

E. B. MILLARD.

Infra-red transmission and reflection of a number of the aniline dyes. J. B. JOHNSON AND B. J. SPENCE. *Phys. Rev.* [2] 5, 349-58(1915); cf. *C. A.* 8, 3393.—Expts. have been carried out on the absorption and reflection of 25 dyes in the infra-red up

to 12μ , by making use of a special spectrometer (*Astrophys. J.* 39, 243(1914)) and the light from a Nernst glower. There is a similarity in the transmission curves for related compds., but the theory that certain groups in a chem. mol. give rise to definite absorption does not hold for these complex substances with any degree of consistency. The bands of max. reflection in general correspond with periods of weak transmission, though the evidence furnished does not seem to be conclusive in detg. whether or not these are bands of metallic reflection. In all probability they are not. E. B. M.

Distillation of liquid air in a magnetic field. R. S. McBRIDE. *J. Am. Chem. Soc.* 37, 1715-8(1915).—Samples of the gas coming off from a Dewar tube placed in a field of 10,000 lines of force per sq. cm. were compared with the gas from a similar tube contg. some of the same specimen of liquid air evapg. in the absence of a field. Less O came off during the early part of the distn. from the flask in the magnetic field, showing a tendency toward better sepn. in the field. Adding Fe filings to concentrate the field had no appreciable effect on the sepn. which was at best but little better than without the field. E. B. MILLARD.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

Advances in the study of radioactive bodies. FREDERICK SODDY. *Pharm. J.* 94, 696-7(1915).—Report on 2 lectures. S. WALDBOTT.

Character and degree of the radioactivity of the "Kuvak" springs in Penza. P. P. VON VEIMARN. *J. Russ. Phys. Chem. Soc.* 46, 742-5(1914).—An exam. of the H_2O of the "Kuvak" springs gave the following results: The lower the situation of the springs on the slope of the hill, the greater is the radioactivity of the H_2O . The radioactivity is very feeble, and being due not to radioactive solids in soln., but to dissolved emanation, is dissipated slowly even in stoppered vessels, and very quickly if the container is frequently opened. An exam. was also made of commercial samples of H_2O of these springs sold under the name of "detonating ore." They were found to be entirely devoid of radioactivity, and are therefore medicinally worthless. H. M. G.

Radioactivity of the deposits from the Borzhom springs. E. BURKSER. *J. Russ. Phys. Chem. Soc.* 47, 21-5(1914).—Radioactive detns. showed that the deposits of the 2 springs examd. contain 10.08 and 17.89×10^{-13} g. of Ra, and 26.2 and 3.26×10^{-8} g. of Th per g. of deposit, resp. The waters of the springs contain 0.02 and 0.07×10^{-9} g. of Ra per l., while the Th content of the 2 waters is almost identical and amounts to 7.02×10^{-4} g. per l. H. M. G.

The spectrum of Röntgen radiation. A. SOMMERFELD. *Ann. Physik* 46, 721-48 (1915).—A mathematical paper showing that Röntgen radiation produced under a discharge of const. potential will be most intense in the longest wave lengths, while these wave lengths are absent if the potential is alternated. For the former case the max. lies in the infra-red; for the latter in the ultra-violet. But long wave-length radiation is readily absorbed by the radiator, especially in the presence of free electrons, so that the ordinary spectrum seems to be of the alternating potential type. G. L. WENDT.

Dispersion of Röntgen rays. P. DEBYE. Göttingen. *Ann. Physik* 46, 809-23 (1915).—An attempt to explain mathematically Friedrich's interference photographs on the basis of electron rings within the atom. With long waves the diffuse radiation is found to be proportional to the square of the number of electrons in the rings, but with shorter waves the value tends toward the first power. The space distribution demands a dipole in both cases. In the direction of the primary beam the radiation

remains proportional to the square of the number of electrons and shows interferences which are evident as rings in the Friedrich photographs. G. L. WENDT.

Radiations produced by Röntgen rays. J. LAUB. Buenos Aires. *Ann. Physik* 46, 785-808(1915).—The intensity of secondary rays is dependent on the angle of incidence of the primary X-rays on the radiator. With very fine leaves of Al or paper an angle of near 90° is necessary to produce any radiation. L. therefore supposes that the intensity of secondary radiation depends on the number of atoms traversed, the effect being one of bending or refraction. No connection was found between the variation of the intensity of the secondary rays with the angle of incidence and the polarization of the primary rays. New characteristic secondary rays from various elements were measured, the values for the absorption coeffs., $(\lambda/t)_{Al}$ being as follows: Zn, 18.5 and 5.6; Cu, 23.8; Pb, 16.2; Fe, 43.8; Pt, 21.5 and 7.2; C, 0.37; S, 0.21. These secondary rays from C and S are the most penetrating yet known. Their use instead of γ -rays in medicine is suggested. G. L. WENDT.

An emission law for homogeneous Röntgen rays. J. LAUB. Buenos Aires. *Verh. deut. physik. Ges.* 17, 104-8(1915).—An approximate law for the sp. absorption coeffs. of the elements for K-radiation is $(\lambda/t)_{Al} = 1663.5 \times 10^8/N^3$, where N is the atomic number. A more exact value for the elements Fe to Se is $(\lambda/t)_{Al} = 2836.8 \times 10^7/N^3$; for Br to Sn, $1768 \times 10^8/N^3$; and for Sb to Ce, $1164.7 \times 10^9/N^7$. For the L-radiation the value is nL/N^7 , where $L = 3606.8 \times 10^{11}$. For the newly measured rays from Cu, Zn, Pt, etc. (cf. preceding abstr.) the coeff. is nK/N^8 , where n is an integer between 1 and 7, and $K = 1138$. The new rays from C and S probably belong to a class of rays still harder than that of the K- or the L-series.

G. L. WENDT.

A metallic safety Röntgen tube. L. ZEHNDER. *Ann. Physik* 46, 824-36(1915); cf. C. A. 9, 1005.—This tube is unbreakable, allows no leak and gives a radiation 20 times as intense as that of the Gundelach tube. L. claims it can be made 1000 times as intense. An ordinary Gundelach cathode is set into the mouth of a heavy porcelain high voltage insulation tube, the heavy Cu lead wire passing through the tube, at whose other end is an iron valve for sealing after evacuation. A brass cylinder is set into the mouth of the porcelain tube, thus insulated from the cathode. Into the other end of the brass tube is fitted a screw system carrying the adjustable anticathode, a W block set into a massive Cu carrier. Opposite this is a small window in the brass tube covered by a hemisphere of thin glass. The brass case is also provided with a side tube containing charcoal which can be electrically warmed to give the exact regulation of the vacuum. The efficiency of the tube is due to the speed with which heat is carried away, all parts being massive. The electrodes may be water-cooled. The beam is sharply defined by the window. The intense radiation permits very brief exposures and gives very delicate contrasts such as the design on a coin. If the brass case is electrically earthed the tube may be handled while in use and brought close to the patient.

G. L. WENDT.

Spectrum investigations with Röntgen rays. I. ERNST WAGNER. Univ. München. *Ann. Physik* 46, 868-92(1915).—The sep. absorption of sections of the spectrum by Ag and Br renders a photographic measurement of the relative intensities of spectral regions precarious. The wave lengths at which absorption by various metals begins are sharply defined. Stokes' law, that the wave length of the primary exciting ray (λ_A) is shorter than that of the excited characteristic secondary ray (λ_a), is shown to hold for the α , β , and, in the case of Pd, for the γ lines, i. e., for the whole K-series. The "Stokes interval," λ_a/λ_A , is essentially const. for 8 elements. Similar expts. on Au and Pt with the L-series point to a similar relation there and to the universality of this fluorescence mechanism. W.'s measurements agree with Kossel's

(C. A. 9, 1715), development of Bohr's atom, viz., that the frequency of the K-line and that of the L-line added give the frequency of the absorbed primary radiation. More exactly, $\nu_{KA} = \nu_{K\alpha} + \nu_{L\alpha} + \nu_{M\alpha} + \nu_{N\alpha} + \dots$. Calcn. gives the frequencies for the various series as: K, 1.7×10^8 ; L, 0.22×10^8 ; M, 0.03×10^8 ; N, 0.007×10^8 ; O, probably, in the Schumann region. This is a geometric series with a factor of $1/8$ or $1/7$.
G. L. WENDT.

The influence of Röntgen rays on the condensation of water vapor. FRANZ STRIEDER. Univ. Marburg. *Ann. Physik* 46, 987-1008(1915).—In air or O the expansion ratio of 1.25, required by C. T. R. Wilson (*Trans. Roy. Soc. London* 189, 265(1897)) for the condensation of water vapor by gaseous ions, is necessary only if the condensation of droplets is to be produced, immediately upon exposure to the ionizing rays. Exposure for 1 min. to X-rays, from a tube operating at 12 amps., gives condensation at a very small expansion, while an illumination of 8 min. produces spontaneous condensation without pressure change. With 13 amps. only 3.5 min. are necessary. In oxygen-free N and H no condensation takes place below Wilson's expansion limit of 1.25. Following Bieber (*Ann. Physik* 26, 727 (1908)), S. attributes the effect to persistent hygroscopic nuclei of H_2O_2 formed after the production of at. O by the X-rays.
G. L. WENDT.

The distribution of electrons in atoms. ARTHUR H. COMPTON. Princeton Univ. *Nature* 95, 343-4(1915).—It has been shown by Bragg (C. A. 8, 2308) that in the spectra obtained when X-rays are reflected from rock-salt, the intensities of the higher orders rapidly diminish. From a study of the data thus established, C. concludes that the intensities of the different orders cannot be accounted for by assuming that the atoms in the salt crystal are made up of single rings of electrons, or by assuming a uniform vol. distribution of the electrons in spheres. A distribution which fits Bragg's data acceptably is an arrangement of the electrons in equally spaced concentric rings, each ring having the same number of electrons and the diam. of the outer ring being about 0.7 of the distance between the successive planes of atoms. It is pointed out further that if the trains of waves of the primary beam of X-rays are short compared with the distance which the rays penetrate the crystal, certain corrections have to be applied to the exptl. data, and on this assumption it can be shown that the av. distance of the electrons from the center of the atom is small compared with the distance between the atoms.
W. H. ROSS.

The distribution of the electrons in atoms. W. H. BRAGG. Univ. Leeds. *Nature* 95, 344(1915).—B. agrees with Compton (preceding abstr.) in ascribing the rapid decline in the intensities of the higher orders of the X-ray spectra to the fact that the atom should not be treated as a point, but as a distribution of electrons in space.
W. H. ROSS.

Pitchblende of Cornwall, Eng. (PENROSE) 8. Radioactivity and the earth's thermal history (HOLMES) 8.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Reclaiming nickel anodes. ANON. *Met. Chem. Eng.* 13, 453-4(1915); *Iron Age* 95, 1392(1915).—Scrap Ni anodes are reclaimed and made fit for further service by welding (autogenous) together a number of such anodes into one. The saving is about 18 cents a lb. when compared with the cost of new anodes.
C. G. F.

The Ilmenite arc. I. LADOFF. *Elec. Rev. West. Elec.* 66, 691-5(1915).—A short review of the various kinds of additions to arc lamp electrodes is first given. About

40 electrodes of various contents of TiO_2 , Cr_2O_3 , and other materials were prepared and tested. It was found that the 30% TiO_2 ilmenite electrode, although it did not give the highest efficiency, was practically free from slagging and non-starting troubles, and had a reasonably long life. Efficiency tests of ferro-ilmenite and magnetite cathodes established the general superiority of the ilmenite over the magnetite cathode under identical conditions. It was also found that there is a definite interdependence between the amperage (temp.) of the arc and its most efficient length (voltage), shorter arcs being more economical at low amperages and *vice versa*. Cr compds. were ascertained to have a cooling effect. Ferro-ilmenite cathodes containing various amts. of Na, U, V and Ca salts were compared. Those containing U proved most efficient and steady. An increased efficiency of 133 to 195.3% was obtained by using an anode of ferro-ilmenite instead of massive Cu. Cold-rolled steel, V steel and graphite anodes were also tried with an increased efficiency of 212% in the case of V steel and 165% in the case of cold-rolled steel. An arc between ferro-ilmenite (30%) and cold-rolled steel with protected tip gave an increased efficiency over the magnetite arc of 151% at 4 amps. Of this 104% was due to the anode alone. The efficiency attained by the "ilmenite (30%) to cold-rolled steel" arc at 4 amps. is equal to the best quartz tube Hg arc. At 6.6 amps. it reaches the best values of a 500 watt yellow flame arc. The ilmenite electrode efficiency increases more rapidly than any other commercial illuminant with increase in wattage. A description of methods and app. is given.

W. E. RUDER.

The electric strength of air. VI. J. B. WHITEHEAD. *Proc. Am. Inst. Elec. Eng.* 34, 843-65 (1915); cf. C. A. 6, 2361; 7, 2514.—This paper deals particularly with the theories of gaseous conduction and corona formation. Some of the simpler fundamental expts. on the elec. cond. of air are described.

W. E. RUDER.

Electrical porcelain. E. E. F. CREIGHTON. *Proc. Am. Inst. Elec. Eng.* 34, 753-842 (1915).—The author first deals with the testing of porcelain by means of a high-frequency oscillator. This is a combination of a 60-cycle transformer, a condenser, spark-gap, and an oscillation or coreless transformer. The 60-cycle potential charges the condenser, and this in turn discharges through the gap and the coreless transformer. High frequency wave trains are consequently set up and these are of the same nature as those set up in transmission lines. This is the only kind of strain that injures the insulators and consequently elec. porcelain should be tested under these conditions. It is shown that good porcelain insulators of proper design will stand high frequency discharge tests for many hrs., so that even though the test is a severe one it makes it certain that porcelain that will stand up under it is entirely trustworthy. A detailed description of the app. and tests is given. The essential points in the factory process of mixing, firing and glazing porcelain are given. Uniform mixt., uniform plasticity, and uniform shrinkage in drying and firing are very essential. Defective insulators are in general due to accidents of mfg., because the dielectric strength of all porcelains are passably good except for flaws. Details of tests on various types of insulators are given.

W. E. RUDER.

Carrying capacities of rubber insulated wires and cables. ANON. *Elec. Power and Gas* 34, 272-3 (1915).—A table, based upon the National Elec. Code, is given by use of which practical men may read directly the values for various circuits.

W. E. RUDER.

Vacuum tubes for telephone-line protection. F. SCHROETTER. *Elektrotechn. Z.* 136, 77-78 (1915).—A new form of vacuum tube, effective to as low as 130 v., is described as illustrated in cut. An Al anode pin *a* is protected by the tube *b* and placed a few mm. from the fused K-Na alloy cathode *k*. The tube is filled with He, Ne, Ar or a mixt. of these at 1-3 mm. pressure. Such a tube will stand thousands of breakdowns

without change of its critical voltage. Two kinds of connections, as illustrated, may be made. By special methods, voltages as low as 104 may be made to operate these tubes. If *a*, covered with a layer of K, is used as cathode, and a distance of 5 mm. is set between *a* and *k* with an atm. of $\frac{1}{2}$ Ne and $\frac{1}{2}$ He at 2 mm. pressure, a breakdown of 104 v. is obtained. In the scheme of connections A, the fuse *f* (0.5 amp.) is inserted between the telephone transmission line *T* and the exchange line *E*. In the

second case *B* the sepn. is made by a relay consisting of a high resistance *R* (8000–15000 ohms) coil and armature *F*. A brush discharge takes place in the vacuum tube in case of a dangerously high voltage on the line because the high elec. resistance of *R* prevents the current from reaching an intensity sufficient to vaporize the cathode *k* and produce an arc. The relay is excited by current passing through *R* and breaks contact between *A* and *B*. W. E. RUDER.

Pure electron discharge for wireless telegraphy and telephony. I. LANGMUIR. *Gen. Elec. Rev.* 18, 327–40(1915); *Electrician* 75, 240(1915).—An historical review is given of the work leading up to the establishment of the existence of pure electro-emission from hot bodies in the highest vacua. The fundamental principles of this phenomenon are outlined and their practical expression in the kenotron (cf. *C. A.* 9, 1008) a hot filament vacuum rectifier, and the pliotron, a new type of amplifier, is described.

In the pliotron a third electrode, in the form of a grid of very fine wire (0.01 mm.) is added between hot cathode and anode for the purpose of controlling the current flowing between them. The device is similar in construction to the DeForest audion but the operation is in many ways very different. The fig. shows the construction of a small pliotron as used for amplifying radio signals. There have been constructed larger types capable of controlling as much as 1 kw. each so that a large number of these

operated in parallel may be used to control very large amts. of power. The characteristics of this device depend upon the length of hot filament used, the spacing and size of wires on the grid, the size and shape of the anode and the distance between grid and anode. By using a fine grid the current to the anode can be stopped entirely by a very slight neg. potential on the grid, while on the other hand a low + potential will be sufficient to draw a large current to the anode. The use of this device as detector, amplifier, and oscillator in the receiving station and its application to wireless telephony are discussed. W. E. RUDER.

Electrolytic iron. T. D. YENSEN. *Electrician* 75, 119(1915); see C. A. 9, 906, 1892. C. G. F.

Electrolytic iron: Its manufacture, properties and uses. L. GUILLET. *Rev. metal.* 12, 81-94(1915); see C. A. 9, 23, 756. E. J. C.

Platinum plating. G. NIKOLAUS. *Elektrochem. Z.* 21, 193-5(1914).—By using a bath of 4 g. H_2PtCl_6 , 20 g. $(\text{NH}_4)_2\text{PO}_4$, 90 g. Na_3PO_4 and 5 g. of NaCl in 1 l. of H_2O , a pure white deposit of Pt may be obtained. The bath should be boiling while in use; the articles to be plated should be kept in const. motion and a voltage of 6-8 maintained. W. E. RUDER.

Photometry of vari-colored light sources (PIRANI) 2.

Brit., 3,545, Feb. 11, 1914. DETTIFOSS POWER Co. and J. H. LIDHOLM. In the manuf. of calcium cyanamide, the N is supplied under pressure to accelerate the reaction, and the CaC_2 is dild. with inactive substances such as sand, or a carbide of low % is used, to prevent the temp. from rising to the sintering point of the cyanamide, the % of inactive matter corresponding to the pressure used.

Brit., 3,546, Feb. 11, 1914. DETTIFOSS POWER Co. and J. H. LIDHOLM. In the manuf. of calcium cyanamide from CaC_2 and N in a rotary tube furnace, the N, supplied under pressure, is used as a driving-agent for circulating the gas in the furnace.

Brit., 3,547, Feb. 11, 1914. DETTIFOSS POWER Co. and J. H. LIDHOLM. Calcium cyanamide is obtained by heating CaC_2 and N separately or simultaneously to a temp. much above the reaction temp. so that the reaction takes place instantaneously. The finely powdered carbide is sifted through a sieve into N in a tube which is highly heated by elec. current through ring contacts. The N is supplied by a pipe and passes through charcoal between an outer shell and the central tube, and thence through a channel into the central tube. The lower part of the furnace is water-cooled and is discharged as a powder by a screw. The furnace may be heated by arcs, which may be spread into disks. Cf. C. A. 9, 1434.

Brit., 3,654, Feb. 12, 1914. I. H. LEVIN. In app. for making gases such as oxygen and hydrogen electrolytically, anode and cathode compartments are connected by independent off-take conduits with corresponding compartments of a tank, the lower part of which may be contracted. A partition between the latter compartments reaches nearly to the bottom of the tank, where it enters a small trough so as to prevent transference of bubbles while allowing equalization of pressure in the cell compartments. The electrolyte and gas enter the compartments through nozzles projecting the liquid on to a surface, which may be made with baffles to facilitate disengagement of gas. The gases collect in chambers above the tank, provided with level gages. An overhead reservoir for electrolyte communicates by a pipe with the bottom of 1 of the tank compartments. Passages return the electrolyte to the cells.

Platinum toning bath. R. NAMIAS. *Boll. chim. farm.* 53, 140(1914).—N. proposes the following soln. as a Pt toning bath in photography: oxalic acid 1 pt., HCl 5 pts., K_2PtCl_6 1 pt., distd. H_2O 1000 pts.

H. S. PAINE.

Brit., 1,795, Jan. 22, 1914. UNION PHOTOGRAPHIQUE INDUSTRIELLE ETABLISSEMENTS LUMIERE & JOUGLA REUNIS. Chlorohydroquinone and metol are combined for use as a photographic developer, by the method described in 7,163, 1903, for the prepn. of a combination of hydroquinone and metol. The resultant compn. corresponds with that of a combination comprizing 2 mols. of the metol and 1 mol. of the hydroquinone. The developer is made up with Na_2SO_3 with or without alkali.

Brit., 2,704, Feb. 2, 1914. J. CAMPBELL. Natural color cinematography in which the negative is successively and alternately exposed through rotating color filters. Two filters each formed of 2 colors, 1 cold of a blue and a green, and the other warm of a yellow and a red, are used. The filters transmit light from 4100 to 5600 and 5600 to the red end of the spectrum, resp. The 2 colors may be juxtaposed or superposed in each filter in the form of film, or the 2 colors may be applied to a gelatin or like film by spraying in succession, 1 color being allowed to dry before the other is applied. The positive films may have the gelatin dyed with 2 pairs of appropriate colors so that each picture carries its own color film. Details of the filters employed for taking the negative, and of the dyes used for staining the positive film, are given in the specification.

Brit., 3,435, Feb. 10, 1914. P. D. BREWSTER. Production of a color picture from a single exposure on a negative, applicable for ordinary photography or cinematography. The light emanating from the object is divided into 2 color groups, and the negative is sensitized on both sides. One side is sensitive to the colors of 1 color group (say green or blue) and on the other side is a panchromatic emulsion or 1 sensitive to the other color group (say, red). The blue or green sensitive film is transparent, and is stained to act as a filter for the red sensitive film, and the exposure is taken through a yellow filter. Instead of staining the film, a separate filter may be combined with the base, or the base may be colored. If the films are suitably sensitized for the particular color groups, staining the front film or the base is not necessary. After developing and fixing the negative the Ag images are respectively stained blue or green and red or orange, the 2 colors used being substantially complementary. The negative film is printed on a positive film sensitized similarly to the negative film, and so that each side only prints its own color group. The Ag images on the printed positive are then stained or colored in the corresponding colors. Alternatives are prescribed for the various details of the process. For example, the front of the film may be sensitized for the red color group and the back for the green or blue color group. Cyanine and acridine orange are specified as color sensitizers. The light used for printing may contain only the light of the 2 colors for which the emulsions in the positive have been sensitized. For producing the colored negative and positive, the Ag of the images may be 1st converted into AgI and treated with a basic dye, which ppts. the

iodide, giving an opaque image which may be dissolved out with KCN or in an alum bath containing tannin or tartar emetic. For light filters, gelatin stained with picric acid, naphthol yellow or auracin may be used. To obtain a correct balance of color 1 or other of the color pictures may be reduced or intensified, or the comp. of the printing light may be varied and adjusted.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Quantitative blowpipe analysis in the field. G. DELIUS. *Mining Sci. Press* 110, 725-6(1915).—Description of portable field outfit with detailed instructions for carrying out the assay.

Solubility of glass in water. R. F. VON WALTHER. Dresden. *J. prakt. Chem.* 91, 332(1915).—W. suggests the following as a suitable expt. to begin a course in quant. analysis, to demonstrate the solubility of glass in H_2O : Boil in a common liter flask 500 cc. H_2O with sufficient indicator (alizarin) to produce a pale yellow color, until the color changes to reddish violet. Then add 0.01 N H_2SO_4 until the original yellow color is restored. By continued boiling for 1 hr., 18.3 cc. 0.01 N H_2SO_4 were required.

D. BRESE JONES.

Quantitative determination of minute amounts of arsenic. L. RAMBERG. *Svensk. Kem. Tidskrift* 27, 48-65(1915).—The As is removed from the sample as AsH_3 by passing through it a current of H generated by electrolysis in a specially constructed app. This app. consists of 2 chambers sepd. by a porous plate and may be in either one of

two forms. In one form (see Fig. 1) the cathode consists of Hg on the bottom of one of the chambers; the anode is made of a cylinder of Pt foil. The anode chamber is connected with the cathode chamber by a ground glass tubule and side tube, the connecting tube having a porous plate fused over its open end. In the other app. (Fig. 2) the 2 chambers are in one piece with the porous plate fused in the connecting arm. This form has a thick Pb plate in place of Hg as a cathode. In making a detn. 10% H_2SO_4 is poured into the cathode chamber to just cover the porous plate and into the other side a trifle more is poured. The app. is immersed in cold running water up to its neck. The gas outlet tube is connected with a $CaCl_2$ drying tube. Near the further end of this $CaCl_2$ tube is a side tube leading to the As tube with which it is connected by a heavy rubber tube. A 3-amp. current is passed through the soln. and when the air has all been expelled from the app. the burner under the As tube is lighted and the heat gradually increased during 5 to 10 min. The sample which should not contain over 0.1 mg. As, is introduced into the cathode chamber by way of the funnel tube. In about an hour the As will all have been transferred from the sample to the As mirror in the As tube. The capillary of the As tube containing the As is cut off and placed in a stoppered tube having a capacity of 3 cc. (for mirrors in excess of 0.05 mg. the tube

should hold 5 cc.) and is covered with 3 drops NaHCO_3 and enough 0.002 N I soln. to just fill the tube when the stopper is in place. It is then stoppered and the tube is protected from light by an opaque covering. When the mirror has dissolved (15 min. to 2 hrs.) the tube is emptied and washed into a 20 cc. beaker and titrated with 0.002 N AsO_3 soln. A blank must be run. The Hg cathode gave better results than the Pb cathode. The errors shown by the author's tabulated results range from -0.5 to $+1\%$. Certain precautions are mentioned and a historical summary of 5 pages is given.

A. R. ROSE.

Identification and determination of arsenic in organic compounds. L. BARTHÉ. *Bull. soc. pharm. Bordeaux* 1914, Aug.-Dec.; *Repert. pharm.* 27, 144-7(1915).—B. compared the methods of Bougault and Bressanin for identifying As in org. compds. The reaction of Bougault, that of a mixt. of HCl and H_3PO_4 with sometimes a few drops of an I soln. added, is reducing. That of Bressanin is based on the insolubility of AsI_3 in H_2SO_4 or HCl , KI being the source of the I . The former reaction gave negative results in the cold but when heated for 20 min. ppts. were obtained for Na methylarsenate, atoxyl, arsacetin, "Hectine," "Enesol," salvarsan and neosalvarsan. No ppt. was given with Na cacodylate. Bressanin's reagent gave a ppt. in all the above cases. Bougault's reaction is inconclusive since it also reduces other organo-metallic compds., especially those of Hg . Moreover neither of the above methods is reliable since they do not insure complete decompn. of the organic As compd. In cases of poisoning the Marsh test is indispensable. Individual methods are described for decomp. various As compds. For all quant. detns. as sulfide the As compds. must be oxidized.

J. W. SHIPLEY.

Detection of amyl alcohol in alcoholic solutions. HUGO HOFLANDER. *Boll. chim. farm.* 52, 5(1913).—Twenty-five cc. of the brandy or alc. liquor under exam. are distd. with 1 cc. N KOH . After distn. of as much of the mixt. as possible, 5 cc. of the distillate are boiled for approx. 1 min. with 5 cc. glacial $AcOH$. A single drop of phenylhydrazine is then added to the mixt. and the latter is again boiled. After cooling to room temp. conc. HCl is carefully poured upon the surface of the above liquid; if amyl alc. is present, a pronounced green coloration (emerald green if the conc. of amyl alc. is sufficiently great) is produced at the zone of contact of the 2 liquids. The dark coloration which is sometimes produced at this zone of contact is without importance in so far as the presence of amyl alc. is concerned. The production of the green coloration is attributed to the formation of acetylamylphenylhydrazine hydrochloride. The occurrence of the green coloration under the conditions of the test is believed to be characteristic of amyl alc.

H. S. PAINE.

Rapid organic combustions. MARIE REIMER. *J. Am. Chem. Soc.* 37, 1636-8 (1915).—A method is described whereby, by means of a layer of CeO_2 asbestos 2 cm. long in the usual combustion app., excellent analyses of such substances as succinic, salicylic, benzoic acids, sugar, $C_{10}H_8$, etc., can be made in 9-18 min. and of $AcNH_3$, $AcNHPh$, etc., in 24-8 min.

C. A. ROUILLER.

Morphine in a cadaver. ALIDE GRUTTERINK AND W. VAN RYN. *Pharm. Weekblad* 52, 423-4(1915).—Two and one-half yrs. after death due to morphine, administered in coffee, it was possible to show definitely the presence of this drug in the stomach and liver. After the usual treatment it was detected by the following methods: Marquis' reagent, Fröhde's reagent, by $FeCl_3$ coloration, the coloration with $FeCl_3$ and $K_3Fe(CN)_6$, and the liberation of I from HI . Crystals of morphine were also obtained by soln. in dil. HCl , evapn., soln. in a drop of water, and the addition of Na_2CO_3 . Only a very small amt. was found in the portion from the liver.

P. v. D. M.

Estimation of uranium and phosphorus. H. D. NEWTON AND J. L. HUGHES.

J. Am. Chem. Soc. **37**, 1711-5 (1915).—U was estd. (in the absence of Fe) by reducing with $\text{Ti}_2(\text{SO}_4)_3$, oxidizing the excess Ti salt with Bi trioxide and reduced Bi, filtering off the remaining Bi salt and titrating the U with KMnO_4 . The method was adapted to the detn. of P, if phosphate soln. was treated with $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ and HOAc, then with an excess of $\text{UO}_2(\text{NO}_3)_2$, and the ppt. filtered off on a Pt Gooch funnel. After the ppt. was dissolved in 16% H_2SO_4 it was reduced with $\text{Ti}_2(\text{SO}_4)_3$ and titrated with KMnO_4 as above. An agreement between the amt. of P taken and that obtained was found, the errors being about 0.0001 g. E. B. MILLARD.

Improved test for potassium. L. W. WINKLER. *Z. angew. Chem.; Zentr. Pharm.* Apr. 14, 1915; *Pharm. J.* **94**, 741 (1915).—The test for K with tartaric acid often fails, due to supersatn. If tartaric acid is added in powder form, the test always succeeds, probably on account of traces of $\text{KHC}_4\text{H}_4\text{O}_6$ present. In 10 cc. of the neutral liquid dissolve 0.5 g. cryst. AcONa , then add 0.5 g. powdered tartaric acid, shake well. In the absence of K, (NH₄, Rb, Cs), the liquid remains clear. S. WALDBOTT.

Qualitative reaction for the detection of nitrates. A. TINGLE. *J. Soc. Chem. Ind.* **34**, 393 (1915).—The reagent consists of a soln. of 2 g. salicylic acid in 30 cc. H_2SO_4 (d. 1.84). If the substance to be tested is solid it is heated in a test tube with an excess of the reagent. A drop of the resulting liquid is withdrawn on to a cold, white, porcelain slab and 2 or more drops concd. KOH added to alk. reaction. The development of a yellow or orange coloration shows the presence of nitrates. If the material be in soln., 2-3 drops are warmed carefully with 2-3 drops of the reagent to the development of acid fumes. When cool, add a slight excess of KOH as above. A distinct yellow color is obtained from 1 drop 0.1% KNO_3 . The presence of halides does not interfere with the test. ISADOR MILLER.

Determination of chlorine, bromine, and iodine in the presence of each other. A modification of Baubigny's method. JULIUS BEKK. *Chem. Ztg.* **39**, 405-6 (1915).—Ppt. with an excess of AgNO_3 , wash on an asbestos or glass-wool filter, dry and weigh. Ppt. a second portion and treat the moist, washed Ag salts (0.3-0.4 g.) for 30 min. with a soln. of 2 g. $\text{K}_2\text{Cr}_2\text{O}_7$ in 30 cc. concd. H_2SO_4 at 95°, converting the I into HIO_3 and liberating the Cl and Br. Toward the end of the reaction a stream of air is led through to remove any Cl and Br from the soln. which is then dild. to 300-400 cc., filtered and the HIO_3 reduced by adding, drop by drop with const. stirring, a concd. soln. of Na_2SO_3 until a faint odor of SO_2 remains after standing 10 min. (under certain conditions an excess may result in a partial reduction of the AgI). The pptd. AgI is filtered, washed with hot, dil. HNO_3 , dried and weighed. The filtrate contains the Ag formerly with Cl and Br. This is pptd. as AgI, filtered and weighed. From these 3 wts. the Cl, Br, and I are easily calcd. Analyses are given showing the method to be accurate, as a rule, within less than 0.15%. Cf. *C. A.* **5**, 2473. J. H. MOORE.

Sulfites, thiosulfates and polythionates. I. A. SANDER. *Z. angew. Chem.* **28**, I, 9-12 (1915); cf. Feld, *C. A.* **5**, 1886, 3023.—Feld's statement that HgCl_2 reacts with polythionates completely after long boiling is incorrect. With tetrathionate 15 min. are enough when the soln. is boiled. At room temp. more time is necessary. The presence of chlorides retards the reaction. The oxidation of SO_2 by HgCl_2 is not quant. with concns. greater than 2 g. SO_2 per l. At higher concns. SO_2 escapes unoxidized from the boiling soln. If an excess of HgCl_2 soln. is added to a soln. of NaHSO_3 , in the cold, titration of the acid formed corresponds quant. to the amt. of NaHSO_3 taken. For titration of SO_2 2 mols. of NaOH are necessary for each mol. of SO_2 present, the SO_2 being first transformed to NaHSO_3 . These reactions are of value for the detn. of free SO_2 in the presence of H_2SO_4 . Titration with alkali, using methyl orange as indicator, gives the total acid present, the SO_2 having been changed to NaHSO_3 . Addition of

excess of HgCl_2 , and further titration with alkali then gives the amt. of SO_2 originally present. Mixts. of SO_2 and HCl cannot be detd. as the NaCl formed interferes with the action of the HgCl_2 . The method of Feld for the estn. of free SO_2 with thiosulfates and polythionates is not satisfactory since the reaction between MnS and SO_2 is not quant. The following procedure is better: First titrate an aliquot with I , thus detg. the total amt. of thiosulfate and SO_2 present. Titrate the H_2SO_4 formed with NaOH . The amt. of thiosulfate and SO_2 is then known. Then neutralize another aliquot with NaOH , NaHSO_4 being formed. Add excess of HgCl_2 and shake the mixt. occasionally for 30–40 min. After addition of NH_4Cl , titrate the liberated acid with NaOH , using methyl orange as indicator. The amt. of liberated acid due to the thiosulfate and sulfurous acid has been ascertained, in the I titration, and therefore that due to the polythionate is known, and the amt. of the latter can be calcd.

W. H. S.

Colorimetric detection of oxalic acid and manganese. J. F. SACHER. *Chem. Ztg.* 39, 319(1915).—On mixing a dil. soln. of a manganous salt with NaOH or KOH soln., allowing to stand till the $\text{Mn}(\text{OH})_2$ is partially oxidized by the air and then adding dropwise an aq. soln. of $\text{C}_2\text{H}_2\text{O}_4$, the ppt. dissolves and a sharp red coloration results. After adding NaOH , the oxidation is accelerated by warming the soln., which must be cooled before completing the test, as the color does not form at higher temps. Reducing substances (SO_2 , N_2O_5 , Fe^{2+} , etc.) prevent the color formation, as does an excess of $\text{C}_2\text{H}_2\text{O}_4$ or other acid, the soln. becoming colorless or yellow according to the Mn concn. From expts. with KMnO_4 and $\text{C}_2\text{H}_2\text{O}_4$, it is concluded that the color is due to the formation of a double salt. *Oxalic acid*: 0.25 mg. suffices, if soln. is not too dil. Dissolve 2–5 mg. of MnSO_4 in a few drops of H_2O in a test tube, add a drop of NaOH or KOH soln., warm till oxidized, cool; add the soln. to be tested (free from reducing substances) dropwise; with 0.5 cc. of a 0.05% or more soln. of $\text{C}_2\text{H}_2\text{O}_4$ the red color forms. Dil. solns. may be concd. by evapn. If the $\text{C}_2\text{H}_2\text{O}_4$ soln. contains free mineral acid, neutralize with NaOH , acidify with H_2SO_4 , spotting on litmus paper, and proceed as above. S. detects $\text{C}_2\text{H}_2\text{O}_4$ in the presence of HCl , H_2SO_4 , HNO_3 , H_3PO_4 , AcOH , butyric, valeric, citric, tartaric, lactic, benzoic, and salicylic acids, phenol and small amts. of HCO_2H . Tannic acid interferes. In the presence of tannic acid and HCO_2H , the $\text{C}_2\text{H}_2\text{O}_4$ is sepd. as CaC_2O_4 and the latter decomposed with a little H_2SO_4 . *Manganese*: To the acid soln. for test, add NaOH , warm, cool, and add 0.5 N $\text{C}_2\text{H}_2\text{O}_4$ dropwise as above. One part of Mn in 200,000 of soln. is readily detected. S. uses this method for testing lacquers and driers for Mn ; in the presence of Co , the soln. after completing the test is heated to boiling, the Mn complex is destroyed and any color due to Co remains. With larger amts. of Co , on boiling CoC_2O_4 ppts. with a decolorizing

F. W. SMITHER.

Assay of cyanide solutions. C. E. ROODHOUSE. *Mining Sci. Press* 110, 760 (1915).—Modification of the Chiddey process for the detn. of Au and Ag in cyanide solns. To the charge add 20–25 cc. $\text{Pb}(\text{OAc})_2$ soln. (20%) and 1–1.5 g. Zn shavings. Place on hot plate, add H_2O and bring to a boil as quickly as possible. Just before the soln. starts to boil add 1–2 cc. AcOH and boil 1 min. Pour off soln. closely, and add 150 cc. hot 10% HCl ; replace upon the hot plate and cover with watch glasses. Boil 10–12 min. to dissolve the Zn and then fill the beakers with cold water, decant and wash once more with cold water, squeezing the sponges into cubes, after which dry. Time consumed is 45 min. for 12 assays.

ISADOR MILLER.

Determination of gold in blister copper. R. KING. *Mining Sci. Press* 110, 917(1915).—From a well mixed sample, weigh out a $1\frac{1}{2}$ assay ton portion and divide it roughly among 5 Battersea crucibles. In each crucible place 0.8 g. of flowers of S and mix. Cover with from 8 to 10 assay tons of the following stock flux: PbO , 88; Na_2CO_3 , 3; K_2CO_3 , 3; SiO_2 , 6%. Add a light cover of salt. Gradually raise the heat in

the muffle furnace. Fusion is complete in 35 min. See that no Pb is lost in the slag. The Pb button should weigh about 20 g. Scorify the 5 Pb buttons with 1 g. of SiO_2 in a 3 in. Bartlett-shaped scorifier. Continue scorification until the "eye" of Pb is about $\frac{1}{4}$ in. in diam. See that no particles of Pb remain in scorifier after pouring into a shallow mold. After cleaning the Pb of slag, it should be free from Cu and should weigh about 10 g. Cupel and part for 1 hr. in a water bath in a mixt. of 7 parts of H_2O and 1 part of HNO_3 . Wash bead and part in concd. HNO_3 for $\frac{1}{2}$ hr. Wash, dry, anneal and weigh. Ag results by this method are too low, but the method is satisfactory for Au.

E. W. BOUGHTON.

Technical examination of ferrovanadium. A. HEINZELMANN. *Chem. Ztg.* 39, 285-7 (1915).—The properties, uses, comp., analysis, etc., of Fe-V are briefly discussed. H. has found in a few cases a C content as high as 6% and an Al content of 10-15%; the latter could be worked with a file. *Method:* treat 0.5 g. of the fine alloy in a large Pt crucible or a deep 100 cc. Pt dish with a little H_2O , add 10 cc. concd. HF, cover and let stand till evolution of H is over; add dropwise 2 cc. of 25% HNO_3 and after the main reaction is over (about 3 min.) warm on the steam bath till reaction is complete and alloy is in soln. Wash off cover with a little H_2O , evap. to dryness on steam bath, add 10 cc. of concd. H_2SO_4 and heat on sand bath to SO_3 fumes; cool, add about 100 cc. of H_2O and boil till salts dissolve, giving a clear emerald green soln. of V^{IV} , V^{V} , and Fe^{II} . Transfer to a 200 cc. flask, make up to mark with H_2O , mix and use 50 cc. for detn. of Fe and V. To the aliquot in a spacious Erlenmeyer flask add a few drops of H_2O_2 till soln. becomes decidedly reddish brown, dil. to 250 cc., neutralize with Na_2CO_3 soln. till a slight turbidity remains. Add 40-50 cc. of concd. SO_2 soln. and heat slowly to boiling (to reduce Fe^{II} to Fe^{I} and V^{V} to V^{IV}), add 20 cc. of 30% H_2SO_4 , insert stopper provided with inlet and outlet tubes and boil 20 min. (till SO_2 is expelled) with a current of washed CO_2 passing through flask. Titrate hot with 0.1 N KMnO_4 the Fe^{II} + V^{IV} = A. To det. V, add 0.1 N $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ soln. from a buret till in slight excess (use $\text{K}_2\text{Fe}(\text{CN})_6$ and spot plate) and then 3-5 cc. more; add 0.1 N KMnO_4 till the spot test with $\text{K}_2\text{Fe}(\text{CN})_6$ shows no blueing after 20 sec., read buret and titrate with the KMnO_4 till faintly reddish brown; reading = B, which multiplied by 0.00512 = wt. of V. $A - B \times 0.00559 = \text{Fe}$. The method may be executed in a HCl soln. if the HCl concn. is kept below 0.25 N; in this case, instead of adding 20 cc. of 30% H_2SO_4 , add 20 cc. of the Zimmermann-Reinhardt "titrating mixt." (67 g. MnSO_4 , 138 cc. H_3PO_4 , (d. 1.70), 130 cc. concd. H_2SO_4 , H_2O to make 1 l.). Methods for Al, P, As, C, etc., will be reported in another paper.

F. W. SMITHER.

The influence of phosphoric acid in the determination of "available" chlorine in "chloride of lime." E. KEDSODY. *Mitt. kgl. Materialprüfungsamt.* 32, 534-5 (1914); through *Chem. Zentr.* 1915, I, 806-7.—In the detn. of "available Cl" in CaOCl_2 by adding HCl and KI and titrating with $\text{Na}_2\text{S}_2\text{O}_3$, the addition of H_3PO_4 or Na_2HPO_4 will obviate any error that would be caused by Fe^{II} or chlorates. F. W. SMITHER.

The determination of small quantities of boric acid. G. HALPHEN. *Ann. fals.* 8, 1-2 (1915); *J. Soc. Chem. Ind.* 34, 278.—A modified Bertrand and Agulhon method (cf. C. A. 8, 884, 1312, 2005). H_3BO_3 is collected as Me borate in 0.2 cc. of N NaOH soln.; this is then evapd. to dryness in a small test tube and the residue dissolved in 1 cc. of H_2O plus 2 cc. HCl (1.162). Standards containing known amts. of H_3BO_3 are similarly treated. To all tests is then added 1 cc. of an Et acetate soln. of turmeric, and the resulting red colors compared after 50 min.

H. S. BAILEY.

Factor to be used for calculating the phosphoric acid in Neumann's method. S. L. JODDI. *J. Am. Chem. Soc.* 37, 1708-10 (1915).—Neumann's method for P as modified by Gregersen was both accurate and reliable, but the factor 0.554 (mg. of P per cc. of 0.5 N alkali) was too low. The factor found here was 0.57. It was found best

to allow for CO_2 in the reagents by running a blank rather than by overtitrating with H_2SO_4 , removing CO_2 by boiling, and titrating back with alkali. E. B. MILLARD.

Ionization constants of indicators (PAULUS) 2. Analysis of hypochlorite solutions (GRIFFIN) 18.

Heat transformation of polymorphic minerals. P. N. LASCHENKO. Novocherkassk, Russia. *Proc. Don Polytech. Inst.* 2, 46 pp. (1913).—Heating curves and tables of data for barite, quartz, chalcedony, witherite, marble, iceland spar, aragonite, CaO , opal, magnetite, cassiterite, rutile, brucite, and anatase. B. R. HONOVSKI.

Sulfur from decomposed stibnite from Salva, Casal di Pari, Grosseto. E. QUERCIGH. Univ. Turin. *Atti accad. Lincei* 24, I, 73-9 (1915).—Cf. *Ibid* 23, I, 201. S crystals from this source were measured and are described. E. J. W.

The formation of hard salts, and the secondary transformation of Zechstein salts in relation to the equilibrium scheme of van't Hoff. M. RÓZSA. Budapest. *Z. anorg. Chem.* 91, 299-319 (1915).—Continuation of C. A. 9, 281. A discussion of the processes of metamorphism involved in posthumous transformation in salt beds, resulting in the production of hard salt and other secondary products. G. W. M.

The tachhydrite occurrence in the potash-salt deposits of the Mansfeld basin. P. KLING. Halle. *Dissertation*, Halle 1913; *Centr. Min. Geol.* 1915, 11-7, 44-50.—Detns. are given of Ca and Mg in the salt deposits at frequent intervals to depth of 300 m., with complete analyses, including detns. of Ca and Mg sol. in EtOH, and the corresponding mineral comps., of material from 7 different levels. The max. % of tachhydrite ($\text{CaCl}_2 \cdot 2\text{MgCl}_2 \cdot 12\text{H}_2\text{O}$) present in any sample, calcd. from the EtOH-sol. Ca, was found to be about 10% at 265-272 m. The properties of tachhydrite are then described, and its paragenesis discussed; it shows peculiar replacement phenomena with reference to carnallite. Consideration of the genetic relations, especially the reactions between the various salts present, shows that the tachhydrite is secondary. As the yellow color of tachhydrite has been ascribed to FeCl_3 and to organic matter, without definite proof in either case, this question was further studied. The Fe content proved to be about 0.06%, of which 0.04-0.05 is united to Cl, the remainder being present as hematite; both FeCl_2 and FeCl_3 could be detected. The hematite is irregularly distributed, and is probably derived from decomposed carnallite; no inclusions of FeCl_3 solns. could be found. Crystn. expts. showed that FeCl_3 can not enter into isomorphous combination with tachhydrite, but that FeCl_2 can do so by replacing MgCl_2 to the extent of $\frac{1}{10}$ the amt. of FeCl_2 present in the soln. The yellow color of the mineral therefore arises from the oxidation of original isomorphously combined FeCl_2 to FeCl_3 . Finally it was found that a soln. containing too little CaCl_2 for tachhydrite to form yields at 50° minute isometric crystals with the comp. of MgCl_2 , perhaps + 4 H_2O . E. T. W.

Tschermak's article on "the chemical composition of aluminous augite." H. E. BOEKER. Frankfurt. *Centr. Min. Geol.* 1915, 1-3; cf. B., C. A. 8, 1556; T., C. A. 9, 1447.—T.'s theory that the aluminous augites are combinations of 4 isomorphous components was previously shown by B. to be inapplicable, but as T. has recently reasserted it, B. now points out that as the result of recent expts. it is known that solid soln. plays an important role in such silicates, and although certain end compds. may be assumed to be present for convenience, the real mode of combination of the oxides is as yet unknown.

The minerals are best regarded as solid solns. of the oxides found on analysis, with definite limits of satn. E. T. W.

Rhodusite and abriachanite. G. MURGOCI. *Compt. rend.* 160, 631-3(1915).—Soda-amphiboles, rich in sesquioxides, possess optical properties which vary according to the ratio of Fe_2O_3 to Al_2O_3 . The minerals in question are the most highly ferruginous of the members of the glaucophane series. Two types are noted in this series: rhodusite, with the plane of the optical axis parallel to g' (010) as in riebeckite, and another type containing Al, with this plane perpendicular to g' , as in osannite; this latter type may be called abriachanite. L. W. RIGGS.

The water in stilbite is chemically united. A. BEUTELL AND K. BLASCHKE. Breslau. *Centr. Min. Geol.* 1915, 4-11.—The mineral used was from the granite of Striegau and had the comp. SiO_2 56.35, Al_2O_3 16.80, CaO 7.56, Na_2O 0.82, K_2O 0.58, H_2O 17.79, sum 99.90%, which indicates the formula $\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2 \cdot 6.4\text{H}_2\text{O}$. On dehydration *in vacuo* the mineral gave an essentially continuous curve, but on rehydrating with H_2O vapor the curve showed breaks at many points, corresponding to 14 definite hydrates; the final product had the comp. (doubled because of presence of half mols. of H_2O in some of the intermediate compds.) $\text{Ca}_2\text{Al}_2\text{Si}_{12}\text{O}_{28} \cdot 14\text{H}_2\text{O}$. It is thus believed that the H_2O of stilbite is chem. combined, although here as in many other cases the dehydration curve does not show the true relationship, because the union is so weak that cohesion makes several different hydrates decompose simultaneously. In these cases only hydration curves are dependable. E. T. W.

A meerschaum from the Agram mountains. FRAN TUCAN. Agram (Croatia). *Centr. Min. Geol.* 1915, 73-7.—A white to reddish fibrous mineral occurring in veins in serpentine was analyzed and found to have the comp. of meerschaum, $\text{H}_2\text{Mg}_3\text{Si}_4\text{O}_{10} \cdot 2\text{H}_2\text{O}$; its $d_{100} = 2.02$. The work of Michel on meerschaum (*C. A.* 7, 3097-8) is reviewed, and the presence of 2 phases, a colloid and a crystalloid, questioned, since crystals of the present material, stained by methylene blue and acid-fuchsin, are intensely pleochroic, from blue to red, and therefore look different when viewed in perpendicular directions; the mineral is thus basophilous, but it is completely crystalline and anisotropic. The behavior of the mineral toward a number of other dyes is described. E. T. W.

Monazite from Bom Jesus dos Meiras, Bahia, Brazil. J. UHLIG. Bonn. *Centr. Min. Geol.* 1915, 38-44.—Crystals of monazite of unusual habit from this new locality are described, and 2 analyses of it, as well as 2 of associated magnesite, are given. The monazite is unusual in containing only 0.05% ThO_2 . Methods of analysis are described in detail. E. T. W.

The turquois. JOSEPH E. POGUE. *Mem. Nat. Acad. Sci.* 12, Part II, No. 3, 206 pp.(1915).—A monograph on this mineral including all available information on its history, mineralogy, geology, ethnology, archeology, mythology, folklore, and technology (cf. *C. A.* 8, 1254). No new chem. data are given, but what is known as to its comp. is summarized under "Mineralogy." E. T. W.

Alunite and pyrophyllite in Triassic and Jurassic volcanics, B. C. C. H. CLAPP. Can. Geol. Survey. *Econ. Geol.* 10, 70-88(1915).—See *C. A.* 9, 1022. A. A. K.

The systematic classification of ore deposits. A. SACHS. Breslau. *Centr. Min. Geol.* 1915, 77-82.—The classifications used by previous writers are briefly outlined, and the following new plan proposed: I. primary; (A) pneumatogenous, (1) syngenetic, (2) epigenetic; (B) magmatogenous, (1) syngenetic, (2) epigenetic; (C) hydatogenous, (1) syngenetic, (2) epigenetic; II. secondary. Examples of each class are given and discussed. E. T. W.

Observations on contact metamorphic ore deposits. B. PRESCOTT. *Econ. Geol.*

10, 55-69(1915).—Any hypothesis of contact metamorphism must explain the following: At least to the greatest depth reached the intrusion is often a solidified mass capable of fracture at the time of formation of contact silicates. Ore bodies are localized on points of limestone protruding into the igneous rock. When the latter has embayed the former, megascopic development of metamorphism is almost invariably absent. Marmorization of limestone is often absent when the neighboring monzonite shows heavy silicate development. Mineralizers appear to have been ascending and to have come from below the greatest depth yet reached.

A. A. KLEIN.

Composition of waters in mines of sulfide ores. E. T. HODGE. *Econ. Geol.* 10, 123-39(1915).—Some 50 analyses of mine H_2O are given, and grouped into 5 classes as a result of a survey of the chem. comp., conc., reaction, environment, associated rocks and temps. of waters analyzed. The action of each class is discussed.

A. A. K.

Temperatures that obtain in zones of chalcocitization. W. H. EMMONS. *Econ. Geol.* 10, 151-60(1915).—The est. of heat generated by oxidation of pyritic Cu deposits is somewhat above rather than below the amt. necessary to raise av. mine water 12.7° . The temp. at which chalcocitization takes place is about 30° .

A. A. KLEIN.

Relation of ore deposits to different types of intrusive bodies in Utah. B. S. BUTLER. U. S. Geol. Survey. *Econ. Geol.* 10, 101-22(1915).—These bodies are of 2 types, laccoliths and stocks. The ore deposits associated with the laccoliths and deeper truncated stocks are of slight commercial importance while those associated with the apically truncated stocks are deposits of great value. The lack of large deposits associated with laccoliths is due to the fact that after intrusion they were sealed off from the deep seated source and the amt. of material was too small and differentiation too incomplete to furnish large deposits. In the stocks the differentiation was greater at depth. H_2O and other mineralizers in soln. rose toward the surface while heavier minerals sank to greater depth. The deeper truncated stocks are regarded as probably remnants from which the portion in which the metals were conc. has been eroded.

A. A. KLEIN.

Geology and ore deposits of Red Cliff, Colo. A. H. MEANS. *Econ. Geol.* 10, 1-27(1915).—The deposits may be divided into: fissure veins in granite, carrying Au, Ag, Cu, Pb, Zn; replacements in quartzite consisting of sphalerite, galena, Au, Ag; replacements in limestone comprizing sphalerite, chalcopyrite, pyrite and smithsonite. Two theories of origin are discussed.

A. A. KLEIN.

Silver in argentiferous galena ores. A. E. NISSEN AND S. L. HOYT. Univ. Minn. *Econ. Geol.* 10, 172-9(1915).—From a metallographic study, using HNO_3 as etching agent, the following conclusions have been reached: Ag occurs as argentite in some primary and in some secondary argentiferous galena ores. The limit of solid soln. is below 0.2% Ag_2S . A eutectic is not developed in concs. below 2.7% Ag_2S .

A. A. KLEIN.

Copper deposits in the red beds of Oklahoma. A. E. FATH. U. S. Geol. Survey. *Econ. Geol.* 10, 140-50(1915).—Cu minerals occur as nodules and as replacements of carbonaceous material. The ore is of very low grade. The Cu is a replacement of an earlier sulfide mineral and its pptn. follows the general rules of secondary sulfide enrichment.

A. A. KLEIN.

Iron ores of igneous origin in eastern Greece and their transformations. C. A. KENAS. *Compt. rend.* 160, 633-5(1915).

I. W. RIGGS.

The iron mines of Suhl. PETER RUSSWURM. *Z. prakt. Geol.* 22, 273-7(1914).—R. outlines the history of the mines located near the "Randspalte" south of the Thüringian Forest, some of which have been worked for several centuries. The ores appear in part as metasomatic replacements of Zechstein, and in part as veins of hematite.

To the first group belong the Stahlberg mines and to the latter those at Suhl. The hematite is of excellent quality, containing some Mn, but free from S and P. Some of the gang is high in SiO_2 , but in general it is an easily smelted ore. H. L. OLIN.

Notes on the genesis of the Huelva district pyrite and manganese ore deposits. R. PILZ. Heidelberg. *Z. prakt. Geol.* 22, 373-7(1914).—P. concludes that the Mn deposits are probably of sedimentary origin, while the schists originated chiefly from deep-sea sediments. M. E. SPARKS.

Pitchblende of Cornwall, Eng. R. A. F. PENROSE, JR. *Econ. Geol.* 10, 161-71 (1915).—Pitchblende occurs mostly as one of the minerals of the Cu deposits, also with Sn deposits. It is generally associated with Cu, Fe, Bi, Ni, Co, Pb, and Ag minerals, arsenopyrite, fluorite, autunite, torbernite, zippeite, and uraconite. The ores are much altered. A. A. KLEIN.

Occurrence and origin of bauxite deposits of Arkansas. W. J. MEAD. *Econ. Geol.* 10, 28-34(1915).—Bauxite and associated clays are products of surface weathering of syenite by normal processes of rock decomp. and are not chem. sediments. They have developed *in situ* as shown by the downward secondary conc. of Al_2O_3 . The texture of the kaolinized syenite has been essential to the alteration of the kaolin to bauxite. The oolitic or pisolitic texture has developed from the amorphous types of bauxite. Besides kaolin, halloysite is also an intermediate decomp. mineral. A. A. KLEIN.

Occurrence of bauxite in central Georgia. JOEL H. WATKINS. *Mining Eng. World* 42, 1073-5(1915).—The bauxite occurs as well defined beds in Cretaceous sediments. It is believed to have formed by the alteration of pure clay in place. E. T. W.

Gypsum in Canada. ANON. *Engineering* 99, 467-9(1915); cf. C. A. 6, 1834; 9, 1022.—An abstract of a rept. of Can. Bur. Mines (1912). 550,000 t. are produced annually. The largest deposits are in Nova Scotia, where beds 100 ft. thick, of 90% $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ are found; but it is found also in every province except Saskatchewan. W. B. JOHNSON.

Geology of the Alpine salt deposits in the Berchtesgaden region, with special reference to the Reichenhaller salt springs. GEORG GILLITZER. Munich. *Z. prakt. Geol.* 22, 263-72(1914).—G. reviews earlier work, discusses geology of the region, and then explains his view of the origin of the salt springs. In principle he agrees with Gumbel, but with modification, considering the springs due to erosion, by water from above, of underground salt deposits. M. E. SPARKS.

The mode of origin of coal. EDWARD C. JEFFREY. *J. Geology* 23, 218-31(1915).—The 2 opposed views in regard to the origin of coal are the "*in situ*" theory and the "transport" hypothesis. J. cites evidence derived entirely from a study of the coal itself. Thin sections were studied under the microscope from samples obtained from numerous states and countries and ranging in age from Devonian to the present epoch. The results, as far as bituminous coals are concerned, from whatever geological horizon obtained, showed in all instances the presence of a greater or less amount of spore material. The high spore content is interpreted as clear evidence of the formation of the coal in open water, as against the peat hypothesis. Coal is thus not to be regarded as a compost heap, but a sedimentary deposit. Where the spore material is abundant a cannel or an oil shale results. Where it is plentiful but not superabundant we have coking and gas coals, and where the spore content is small, lean or ordinary bituminous coals are formed. W. F. HUNT.

The demonstration of pumice-formation. K. ENDELL. Berlin. *Centr. Min. Geol.* 1915, 69-72.—A small crucible is filled with pieces of obsidian from Lipari the

size of peas, placed in a vertical tube furnace heated to about 500° , and then raised as rapidly as possible to 1000° . The expansion of enclosed gases (HCl , SO_2 , CO_2 , etc., according to Brun) causes the formation of a spongy mass of pumice-like material, which swells up above the mouth of the crucible. Rocks of deep-seated origin do not form a sponge, but m. slowly to a glass. The mineralogical changes observed on heating a specimen of granite are described. E. T. W.

The principle of saturation in petrography. S. J. SHAND. Stellenbosch, S. Africa. *Geol. Mag.* [6] 1, 485-93(1914).—S. reaffirms his belief (*C. A.* 8, 889) in the principle that rocks indicate by their minerals whether SiO_2 was present in excess or not when they consolidated from the magma; and conversely that if the magma was satd. certain minerals necessarily resulted—in this opposing recent views of Scott who holds that temp. is an essential factor. (*Ibid* 319.) R. C. WELLS.

The principle of saturation. A. SCOTT. *Geol. Mag.* 2, 160-3(1915).—Reply to Shand (cf. preceding abstr.). R. C. WELLS.

Studies on the Pfahl of the Bavarian Forest and its associated rocks. H. OCHOTZKY. Würzburg. *Dissertation*, Würzburg, 1914; *Centr. Min. Geol.* 1915, 50-1.—Continuation of *C. A.* 8, 1946. The rocks of this region are chiefly granitic in character, but there are also marginal areas of basic rocks. Much intrusion of lamprophyric and aplitic material has also occurred, some injection gneisses having been formed. As a consequence of tectonic phenomena considerable metamorphism has occurred, but the resultant rocks are identical in chem. comp. with the original ones, differing only in structure and mineral content. The quartzite of the Pfahl itself owes its origin to thermal processes, having been deposited by juvenile waters. The rocks are radioactive to only an insignificant degree. E. T. W.

Contributions to the petrography of Java and Celebes. JOSEPH P. IDDIGS AND EDWARD W. MORLEY. *J. Geology* 23, 231-46(1915).—I. and M. record the chem. analyses and petrographic descriptions of leucitic lavas from Mt. Mouriah, Java, and point out certain chem. and mineral relationships between these lavas and the shonkinites and nephelite syenites in the vicinity of the Pic de Maros in Celebes. The leucitic and shonkinitic rocks are chem. similar, being low in SiO_2 , high in K_2O , and relatively high in Al_2O_3 and CaO . Mineralogically this is expressed by leucite in the lava of Mt. Mouriah and of orthoclase and biotite in the rocks from Pic de Maros, while augite is a prominent constituent in both. The main contrast between the 2 groups is the crystn. of leucite and absence of nephelite, without any considerable amount of orthoclase and biotite, in the leucitic lavas, while in the intrusive rocks of the Pic de Maros there is no leucite but considerable nephelite in some instances, abundant orthoclase and biotite and an absence of noticeable amts. of Ca-Na feldspar. W. F. HUNT.

Some rocks of Terra del Fuoco. I. Eruptive rocks. FREDERICO MILLOSEVICH. Florence. *Atti accad. Lincei* 24, 1, 22-7(1915).—Amphibole-granite, aplite, granite pegmatite, syenite-diorite pegmatite, amphibolitic diorite, porphyrite, augite-porphyrity, uraltic diabase and peridotite with quartz (quartzose wehrlite) from this locality are described. E. J. WITZEMANN.

Granitic area of Rokan (Middle Sumatra) and contact phenomena in the surrounding schists. A. BROUWER. *Proc. Akad. Wetenschappen* 17, 1190-1202(1915).—A description of the biotite-granites, mica-granites, quartz-diorites, gneissoid-granites, and pegmatites of this region is given; the surrounding schists and their contact phenomena are also described. At the contact of the granites a narrow zone of schists has been feldspatized and the sharp contrast between igneous rocks and sediments has disappeared. Farther away from the contact this feldspatization is lacking. Biotite is the mica found in the feldspatized hornfels near the contact with the granite, mus-

covite appearing farther away. This metamorphism is of an entirely different character from that of the contact-zones of the type "Steiger Schiefer" but is more like that described in Brittany and in the Pyrenees. The pneumatolytic character of the contact metamorphism is shown by the presence of feldspars and tourmaline in the pegmatites.

R. L. SIBLEY.

Two new constituents in the syenite from Ditro. B. MAURITZ. *Földtani Közlöny* 43, 124-7; *Chem. Zentr.* 1915, I, 568-9.—Red or bluish pebbles of corundum are found near the contact between syenite and schist. The rock is not a normal syenite, for all the components are xenomorphic, and microcline, nepheline and titanite are absent. It may be considered a special facies, but may also be regarded as molten schist, injected into the magma. In normal structured schistose syenite from the Ditro road at Tolgyos, scapolite is found in small rounded granules. W. B. J.

Malchite and related dike-rocks in the Odenwald. B. SANDKÜHLER. *Abh. gross. hess. geol. Landesanst.* 5, 193-258(1913); *Neues Jahrb. Min. Geol.* 1915, I, ref. 58-9.—The geological relations show that malchite is a granitic lamprophyre rather than an aplitic gabbro-diorite, as usually assumed. This is confirmed by the chem. character, especially the low SiO_2 and R_2O and the high RO . There are all gradations between malchite and true lamprophyres. E. T. W.

The Permian eruptive rocks from the Bavarian Palatinate. I. KUSELITE. M. SCHUSTER AND A. SCHWAGER. *Geogn. Jahresh.* 23, 43-59; *Chem. Zentr.* 1915, I, 568.—Kuselites are intermediate alkali-rocks, with predominating Na_2O and more MgO than CaO , therefore classed as augite-keratophyres. They form, with their higher MgO content, one pole of the keratophyres, while the other is composed of MgO -poor, and partly alkali-rich rocks, the two poles being related to each other as diorite to granite. They are further related to the augite- and bronzite-porphyrates on the one hand, (also to certain quartz-biotite (augite) porphyrites) and to the orthophyres on the other hand. Indeed, kuselite and augite-orthophyre stand in such a relation as the keratophyres and augite-orthophyres of the Harz. W. B. JOHNSON.

A porphyrite from Dürrenhennersdorf, Saxon Lausitz. JOHANNES BEGER. *Leipzig. Centr. Min. Geol.* 1915, 65-9.—A petrographic description with analysis of the rock of a small dike. In structure it is like kuselite (cf. preceding abstr.), but in comp. it clearly belongs in the series of quartz-porphyrates and porphyrites. E. T. W.

Geology of the North American Cordillera at the 40th parallel. II. REGINALD A. DALY. *Geol. Survey Canada, Dept. Mines Memoir* 38, 547-799(1915).—Chiefly petrographic and physiographic with the following chem. considerations: (1) Until more is known of the behavior of silicate rocks at very high pressures, it is impossible to say how much cooling tension is left unrelieved by compressive extension at the end of the period in which conditions have been ripened for mountain building. (2) The chem. soln. of rock is probably more rapid beneath the forest cap than it is above the tree line, where the amount of vegetable acid is at a minimum. (3) D. proposes a theory to account for the development of dolomites and limestones of pre-Silurian age. Recalling that the evolution of higher animal types from primordial soft-bodied, simple types was very slow, and supposing that the bulk of marine animals were free swimming and that the sea was thoroughly tenanted with such animals, then during life's evolutionary period it was impossible for animals to secrete limy structures. The carcasses of countless animals would after death fall to the sea floor and decompose. During the putrefaction, $(\text{NH}_4)_2\text{CO}_3$ is given off in large volumes and this substance rapidly converts the chloride and sulfate of Ca into the carbonate. The chem. process is fundamentally the same whether the Ca is abstracted from the ocean water through the building of calcareous hard parts or through pptn. by decaying carcasses. Putre-

faction caused the generation of H_2S from sulfates, and this, being poisonous, delayed the evolution of bottom scavengers. The scavenging system, once established, made it possible for river-borne Ca salts to accumulate in the sea. Na and Mg salts are the dominant salts in the sea today and it is simplest to assume that they are so because of a slow evolution of an ocean tending towards a max. ionic stability. The sulfates are relatively subordinate because of the very extensive pptn. of insoluble sulfides and carbonates through the chem. influences of living or putrefying animals. When the acid radicals became either destroyed or permanently bound to bases more powerful than CaO the conc. in the sea water of $CaCO_3$ introduced by rivers first became possible. Then only could have been initiated the epoch in which a series of lime-secreting animals could be evolved unless we assume that a relatively sudden influx of river-borne Ca salts might produce an excess over the amt. used to remove the acid radicals present. $MgCO_3$ comes down only after all the Ca has been pptd. and then only after standing for some time. The hydrous carbonate of Mg can be pptd. by $(NH_4)_2CO_3$ emitted from decaying animal remains, but the pptn. is much slower than in the case of $CaCO_3$ and is retarded by the presence of Ca salts in the soln. (4) The effusive types of rocks are slightly richer in SiO_2 and alkalis and poorer in Fe oxides, MgO and CaO than the respective plutonic rocks. This relation is a result of some kind of magmatic differentiation, probably gravitative. (5) The idea that basalt might have given the world's granites through weather-leaching and remelting of the leached out products was shown to be unsound by considering the Na:K ratio; if this were the case, the ocean would contain 3 times as much Na as at present. (6) A new theory of volcanic action is offered: that the emission of incandescent matter at the earth's surface takes place by the partial or complete foundering of batholithic roofs. The heat emanating from a central vent of a volcano is not primary but is the product of chem. reactions chiefly among the gases in the lava columns and this explains the long lives of many volcanoes for the vents are kept open by the manufacture of heat by exothermic gaseous reactions as well as by the convective transfer of this heat. (7) A new classification of igneous intrusive bodies based on the method of intrusion is given and an application of the theory to the 49th parallel rocks is included.

R. L. SIBLEY.

The work of Lacroix on the laterites of French Guinea. L. L. FERMOR. *Geol. Mag.* 2, 28-36, 77-81, 123-28(1915).—F. discusses L.'s nomenclature of laterites, which is based on the proportion of "lateritic constituents." Gibbsite is the only cryst. hydroxide of Al found; bauxite is merely a rock of variable comp., containing colloidal Al_2O_3 . Limonite is $2Fe_2O_3 \cdot 3H_2O$, while its colloidal variety is called stilpnosiderite (Ullmann, 1814); goethite and turgite are not mentioned. The cryst. form of Al silicate is kaolinite, the colloidal form existing in 2 varieties, the cryptocryst. halloysite and an isotropic form. Attempts to differentiate the silicates from the hydroxides by staining were abandoned. It is believed that the Ti exists as $TiO_2 \cdot H_2O$ and $TiO_2 \cdot 2H_2O$ for which the term *doellerite* is proposed. Three distinct types of laterite are found to result from (1) nepheline-syenites, gabbros, diabases and peridotites; (2) micaceous schists and granites; (3) alluvium composed of debris of non-lateritic origin. Although clays and laterites seem to be the products of decomp. in temperate and tropical regions, respectively, they are not confined to their respective regions. R. C. W.

Outbreak of the mud-volcano Djautepe, Kertsch, March 18, 1914. V. SEDLCHIKOV AND G. KULGAVOV. *Novocherkassk. Centr. Min. Geol.* 1915, 106-13.—The geology of the region and the history of the volcano are briefly outlined, and the recent eruption described. The material emitted is a mixt. of clayey material and H_2O . Exam. showed the presence of quartz, limestone, clay, and glauconite, the last giving a green color to the mass. Qual. tests for Si, Fe, Al, Mn, Ca, K, Na, Cl, P, and S were obtained.

E. T. W.

The gaseous exhalations of Etna. II. G. PONTE. Univ. Catania. *Atti accad. Lincei* 23, II, 402-8(1914); cf. *C. A.* 9, 1449.—The exhalations are at first free from H_2O vapor, which they acquire from the air. Exhalations of eruptions in 1910 and 1911 showed a lower O content as compared with the atmosphere. The O was retained by the lava and used in the oxidation of its constituents. P. found by direct expt. that lava absorbs O and that as a result the FeO content diminishes and the Fe_2O_3 increases. E. J. WITZEMANN.

Radioactivity and the earth's thermal history. A. HOLMES. *Geol. Mag.* 2, 102-11(1915).—Continuation of *C. A.* 9, 1293. The effect of the generation of radio-thermal energy in the earth's crust is to slow down the normal rate of cooling and it is shown that if the earth had originally a temp. of 1000° at or just below the surface the effect of radioactivity sufficient to maintain nearly $\frac{3}{4}$ of the present flow of heat would be to increase the period of cooling from 22 to 1600 million years. The method of estg. geological time by detg. the Pb-U ratios in minerals indicates that the oldest igneous rocks have an age of about 1500 million years. R. C. WELLS.

Coal fields of Canada (DOWLING) 21.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Biographical notice of John Birkinbine. R. W. RAYMOND. *Bull. Am. Inst. Mining Eng.* 1915, 1437-42.—An obituary. A list of papers published by Mr. Birkinbine is given. E. J. C.

Yields and wastes with special reference to puddling. J. E. FLETCHER. *Iron Coal Trades Rev.* 90, 564-6(1915).—The amt. of fettling oxides, $FeO \cdot Fe_2O_3$, required in puddling 100 lbs. of a standard pig iron containing C 3.5, Si 1.5, P 1.0 and Mn 1.0% is approx. as follows: for elimination of C 17.0 lbs., Mn 1.6 lbs., Si 4.7 lbs., and P 4.0 lbs. F. gives extensive tables showing the possible reactions of the oxide with C, Mn, Si and P and points out that they are dependent largely upon temp. conditions. By a study of these reactions it is easy to compute with fair accuracy the yields possible when working with any class of pig iron of given chem. analysis. H. L. OLIN.

Relative efficiency of various amalgams in the recovery of gold. F. A. THOMSON AND R. KEEFER. *Met. Chem. Eng.* 13, 367-70(1915).—Plain Hg excelled any of the amalgams in the treatment of a simple Au ore, when free from impurities. In the presence of sulfates, such as are frequently found in oxidized ores, the extn. was much reduced and plain Hg no longer gave the best results. With 5% of $ZnSO_4$ mixed with the ore plain Hg dropped to 4th place in comparison with certain amalgams; with $MnSO_4$, to 7th place; and with $FeSO_4$, to 8th place. When their av. performance under all conditions was considered, Pb and Sn amalgams gave the best results, with plain Hg 3rd. The relative effect of sulfates in lowering the extn. has also been detd. $FeSO_4$ caused an av. drop of 15.4%, $MnSO_4$ of 20.1%, $ZnSO_4$ of 25.8%. The injurious effect is due to the coating of the plates caused by the presence of sulfates, and in general the amalgams which gave high extns. showed less tendency to coat than the others. It appears that Hg has a greater affinity for Au when pure than when any other metal is amalgamated with it. In those cases where an amalgam shows a higher extn. than Hg alone, the effect is not caused by any increased efficiency due to the presence of the foreign metal, but rather to the superior resistance of the amalgam to the effects of impurities. With reference to ability to remain bright and clean in the presence of sulfates T. and K. have confirmed Aaron's results so far as Cd-amalgam is concerned,

this heading the list; the other amalgams follow about in the order named: Pb, Sn, Au, Ag, Na and Zn. Plain Hg was coated worst of all. C. A. NOWAK.

Effect of carbon in contact with auriferous cyanide solutions. W. R. FELDMANN. *Inst. Mining and Met., Bull.* 127; *Met. Chem. Eng.* 13, 389(1915): cf. C. A. 9, 1891.—By post-treating, with sulfide solns., sand residues from which a max. possible extn. had previously been recovered by cyanide treatment, a further extn. has been obtained, from a larger number of samples, and there is some promise that an economical post-treatment may be evolved on these lines. The pptn. of the Au from the sulfide solns. (in which the Au is held as alk. aurocyanide with hardly any free alk. cyanide, but a large excess of alk. sulfide) appears to be best effected by contact with metallic Cu. C. A. NOWAK.

The working up of lime and magnesia copper ores poor in copper and rich in silica. C. BINDER. *Chem. Ztg.* 39, 370(1915).—B. found that by treating for a few hrs. coarsely pulverized ores containing 1.5% Cu with the alkaline waste liquor from cellulose factories (38° Bé.), 0.82% Cu was removed, and that by adding tartaric acid 1.41% Cu was removed. The latter method seems applicable to sulfide ores also. J. H. MOORE.

The trend of modern blast furnace construction. A. E. MACCOUN. *Proc. Eng. Soc. Western Penn.* 30, 935-72(1915).—Paper and symposium. More substantial hearth jackets are being used with the preference for cast steel or iron jackets with water cooling pipe coils cast into each segment of jacket. The construction of the bosh has been greatly strengthened. Furnace shells of heavy steel plate are employed. A modern 500 ton furnace should have 4 stoves of approx. 22 ft. diam., 100 ft. high, each having 60,000 sq. ft. heating surface. Checker walls should be as thin as is consistent with structural strength. A 500 ton furnace requires 2500 h. p. for operation, of which 1800 h. p. is for blowing engines. H. L. OLIN.

Siphons on solution samplers. ANON. *Eng. Mining J.* 99, 863(1915).—Small particles interfered with the operation of the samplers of the Copper Queen Consolidated Mining Co., Bisbee, Ariz., and the balance weight had to be placed so far from the center of rotation that its fastenings were loosened by the jar of its motion. The removal of the siphons allowed the weight to be placed nearer the center of rotation and the small quantity of H₂O left in the pockets did not cause jar, not being rigidly attached. W. B. J.

The Rainbow (cyanide) Mill, Oregon. W. M. DAKE, JR. *Eng. Mining J.* 99, 1103-6(1915).—A detailed description with flow sheet of this cyanide mill. It is equipped for all-slime treatment and uses Pachuca tanks for agitation. Zn-dust pptn. is practiced, the melting being done in oil-fired tilting furnaces. The ore is quartz and andesite carrying gold. Extn. reaches 95.6%. E. J. C.

Large blast-furnace gas engines. H. HUBERT. Liège Univ. *Engineering* 99, 662-6, 688-9(1915).—An illustrated review of recent progress in the design of large blast-furnace gas engines, with special reference to Belgian practice. E. J. C.

Effect of mineralized waters in cyanide mills. T. B. STEVENS AND W. S. BRADLEY. *Ma. Chem. Eng.* 13, 368(1915).—From their experience S. and B. make the following recommendations for the use of mineralized waters: (1) If "salt water" is used it is not usually possible to obtain a protective alkalinity, but it is advantageous to add a small amt. of CaO in order to make use of the protective action of pptd. Mg(OH)₂. (2) A mixt. of "salt and fresh waters" is to be avoided as diln. of the NaCl present causes pptn. of insol. Ca and Mg salts, but if they have to be used the addition of Ca to produce a protective alkalinity is to be desired. (3) The use of all "fresh water" is by far the most satisfactory, but sufficient CaO should be added to it to render it

alk. before it is introduced into the treatment tanks. (4) Unless there be other adverse reasons against it, crushing in cyanide soln. is to be favored when using mineralized H_2O , as the quantity of "make-up water" required is kept at a minimum by doing so. A great deal depends on knowing the exact comp. of the H_2O , and work done in finding out exactly how the positive radicals contained in the dissolved salts are combined with the negative radicals is time well spent. C. A. NOWAK.

Cyaniding practice of Churchill Milling Co., Wonder, Nevada. E. E. CARPENTER. *Bull. Am. Inst. Mining Eng.* 1915, 1317-32.—The ore is chiefly hard oxidized quartz containing some sulfides. Talc occurs in places; this occasionally gives trouble. Tables show tonnage, recovery, costs, etc. The av. content of Au is 0.216 oz., of Ag 19.48 oz. Value is rated at \$15.52. Au recovery varied from 93.8 to 97.3%, Ag from 89.4 to 93.7%. *Treatment:* The ore passes through 2 in. grizzly to Blake crusher, then through stamps, Chilsan mill, Dorr classifier and tube mill. The ore first comes in contact with cyanide in the stamp batteries and in passing those, and the others mentioned, also a (Dorr) thickener, 76.4% of the Au and 72.2% of the Ag are extd., indicating that the ore is unusual. Agitation and washing in Pachuca tanks, thickening, etc., follow. The classifier overflow runs to a thickener from which the overflow goes to pptn. tanks. Thickened slime goes to 4 Pachuca tanks. Tank No. 1 usually shows 4.5 KCN and 1.6 CaO. In winter steam is used in the uplift column, bringing the temp. at times to 85° or 90° F. Oliver filters with dry vacuum are used. Two 8 ft. filters usually suffice, but if the ore contains much talc, a third 14 ft. filter is used. By special arrangement in washing the cake, a material amt. of cyanide is saved. For pptn. shavings cut from sheet Zn are used. Effective pptn. is about 95.2%. Daily tonnage is 2 to 2.5 tons of soln. per cu. ft. of Zn in 24 hrs. Consumption of chemicals per ton of ore: NaCN 1.72, Zn 1.63, Pb 0.94 lb. For good extn. much $Pb(OAc)_2$ is required. The ppt. contains in the dry 63.5% bullion, of which 6.15 is Au and Ag. No treatment with acid is necessary. It is dried down to about 20% H_2O , and smelted in a furnace using crude oil. E. WALLER.

Testing oil for flotation process. J. COURTS. *Australian Mining Standard* Apr. 8, 1915; *Met. Chem. Eng.* 13, 389-90 (1915).—Of the many tests required for this process, one of the most important is the testing of the active floating agent. Conditions of the tests should follow as closely as possible the presumed actual conditions of operation. C.'s discussion pertains mainly to eucalyptus and resinous oils. The testing of oils is carried out by comparing the sample with measured quantities of a standard oil. Detailed procedure is given. C. A. NOWAK.

Comparative furnace efficiency. R. J. WEITLANER. *Met. Chem. Eng.* 13, 357-61 (1915).—W. has tried to bring the question of comparing furnace efficiencies on a more uniform basis by means of the heat content in metal and he has given simple formulas by which this may be easily obtained. These formulas can also be used to develop a uniform system of cost comparison. C. A. NOWAK.

C. A. ROUILLER.

Polarimetric researches on the modifications which tartaric acid undergoes during fusion. G. BRUHAT. *Ann. chim.* 3, 121-40(1915).—Biot (*Ann. chim. phys.* [3] 29, 35) reported that the $[\alpha]_D$ of *d*-tartaric acid (A) in H_2O was the same after as before fusion, but that if H_3BO_3 was added to solns. of (A) the $[\alpha]_D$ of the fused product was at first $< [\alpha]_D$ of (A), gradually increasing until the $[\alpha]_D$ of the 2 solns. were identical. Bruhat has repeated Biot's work with a delicate Lippich polarimeter, using green ($\lambda = 546 \mu\mu$) and yellow ($\lambda = 578 \mu\mu$) light, and recording the temp. accurately to 0.05° . The concns. of (A) solns. were detd. by titration. Initial rotations were detd. as soon after soln. of fused (A) as possible. A large number of readings, taken at frequent intervals, indicate that $[\alpha]_D$ of solns. of fused (A), to which no H_3BO_3 has been added, diminishes progressively during 3 months, finally reaching a const. value. 2 stages of the reaction were noted—a stage of rapid decrease in $[\alpha]_D$, completed in a few hrs., and a subsequent stage of very gradual decrease in $[\alpha]_D$. B. has clearly shown these phases of the reaction by means of tabulated data and graphs. When fused (A) solns. are treated with H_3BO_3 , the reaction also proceeds in 2 stages: a period of slight initial decrease in $[\alpha]_D$ being followed in less than a day by a period of gradual increase in $[\alpha]_D$. The latter period is also marked by an increase in rotatory dispersion. Other chemists have reported that during fusion (A) is first converted into metatartaric acid (its isomer), which on further heating forms ditartaric acid, $(\text{C}_4\text{H}_4\text{O}_6)_2\text{O}$ (B), which in turn passes into tartrelic acid and finally into the insol. tartaric anhydride. B. interprets his results as follows: In the aq. solns. of fused (A) alone, the slight initial decrease in $[\alpha]_D$ is probably due to the rapid reconversion of meta-tartaric into (A), whereas the 2nd phase of gradual decrease in $[\alpha]_D$ marks the slow hydration of (B) with formation of (A). (The presence of (B) in B.'s solns. was demonstrated by formation of the H_2O -sol. Cu salt.) In the case of fused (A)- H_3BO_3 solns., the explanation is as follows: H_3BO_3 is without action on (B) but reacts with (A) as rapidly as

it is formed from (B), yielding tartaroboric acid (C), which has an $[\alpha]_D$ 4 times as great as that of (A) and much greater than that of (B). The formation of (C) is characterized by augmented rotatory dispersion.

LOUIS E. WISE.

Syntheses by means of organometallic zinc derivatives. γ -Chloro ketones and their transformation products. III. HENRI WOHLGEMUTH. *Ann. chim.* 3, 141-93 (1915); cf. *C. A.* 9, 1602.— γ -Cl ketones, when heated with dry, powdered KOH at 140–70°, yield trimethylenic ketones, $R.CH.CH(COR').CH_2$ (cf. Lipp, *Ber.* 22,

1207). If R' is an aryl group, R' is ordinarily a by-product of the reaction. The following products were synthesized: *methylcyclopropyl ethyl ketone* (A), from $MeCHCl-(CH_2)_2COEt$, b_{700} 144–5°, possessing a penetrating, rather pleasant odor; *oxime*, liquid, b_{11} 99–100°; *semicarbazone*, leaflets, m. 96°; *methylcyclopropyl phenyl ketone*, from $MeCHCl(CH_2)_2Bz$, $b_{16.5}$ 121°, purified by means of its *semicarbazone*, microcrystals, m. 187°; *p-nitrophenylhydrazones*, brick-red prisms, m. 109°; *cyclopropyl p-tolyl ketone*, leaflets, m. 48°; *semicarbazone*, plates, m. 208–9°. When oxidized with concd. aq. $KMnO_4$, (A) yielded *methylcyclopropylglyoxylic acid*, $CH_3.CHMe.CHCOCO_2H$ (B),

b_{17} 100–1°; *semicarbazone*, microcryst., m. 174°; *phenylhydrazones*, yellow needles, m. 133° on a Hg bath. On treatment with $KMnO_4$, (B) remains unchanged, but 30% H_2O_2 readily converts it into $CH_3.CHMe.CHCO_2H$ (cf. Marburg, *Ann.* 294, 131),

b_{14} 96.5°, d_4^{20} 1.0269, n_D 1.4411; Ca salt, brilliant plates; *acid chloride*, b_{11} 39.5°, possessing a disagreeable odor; *anilide*, prismatic needles, m. 113.5°. When a mixt. of Et_3NH and $MeCHCl(CH_2)_2COEt$ was heated at 150° for 16 hrs. the products formed were (A) and γ -diethylaminobutyl ethyl ketone (in poor yield), b_{12} 101–3°; *semicarbazone*, leaflets, m. 144°. By means of a similar reaction, γ -diethylaminopropyl ethyl ketone (C), b_{11} 95–6°, was obtained in 70% yield. The *picrate* of (C) does not crystallize. Its *semicarbazone*, m. 108°. When treated with 4% Na-Hg (C) is readily converted into γ -diethylaminopropylethylcarbinol, $b_{14.5}$ 110°; *phenylurethan hydrochloride*, platelets, m. 99°; *benzoate* (of C), b_{12} 182°. γ -Cl and γ -Br ketones are not acted upon by Mg. $MeCHCl(CH_2)_2COEt$ does not react with KCN, $CHNa(CO_2Et)_3$, $NaCH(CN)CO_2Et$, or $MeC(ONa):CHCO_2Et$. $EtMgBr$ reacting with $MeCHCl(CH_2)_2COEt$ gives rise to γ -chlorobutyldiethylcarbinol, $MeCHCl(CH_2)_2C(OH)Et_2$, b_{12} 108–9°, readily dehydrated by heating with KOH in MeOH, with the formation of α -methyl- α' -diethyltetrahydrofuran, $CHMe.CH_2.CH_2.CEt_2.O$, b_{700} 151–2°, whose vapors impart a red color to pine

shavings moistened with HCl. Similarly, W. synthesized γ -chloropropyldiethylcarbinol, b_{10} 99–100°, and its deriv., α , α' -diethyltetrahydrofuran, b_{700} 144–5°, possessing an odor suggesting camphor, whose vapors give a reddish brown coloration when the pine-shaving test is applied. The γ -Cl ketones when treated with KCN + HCl at –3° yield the corresponding cyanohydrins. 6-Chloro-3-heptanol-3-nitrile, $MeCHCl-(CH_2)_3C(OH)CN$ (D), viscous liquid, b_{14} 151–2° (slight decompn.) with an odor resembling that of cherry pits; when heated with concd. HCl at 100° for several hrs., it yielded largely α -ethyl- α' -methyltetrahydrofuran- α -carboxylic acid (E), viscous, b_{11} 116–7°, whose *amide*, leaflets, m. 69°, was formed when (D) was heated for several hrs. with 4 mols. KOH in dil. EtOH. The *ethyl ester* of (E), $b_{9.8}$ 84°. 6-Chloro-3-hexanol-3-nitrile, b_{10} 154–5°. α -Ethyltetrahydrofuran- α -carboxylic acid, b_{16-7} 126–7°, b_{718} 234–5°; *ethyl ester*, b_{10} 82–3°.

Synthesis of 1,7-heptanediol and some derivatives of hexane, heptane and octane. R. DIONNEAU. *Ann. chim.* 3, 194–268(1915).—A collective article (cf. *Compt. rend.* 142, 91; 145, 127; *Bull. soc. chim.* 7, 327; *C. A.* 7, 3117).

LOUIS E. WISE.

Diketotriazines. Syntheses of substituted semicarbazides. J. BOUGAULT. *Compt. rend.* 160, 625-7(1915); cf. *C. A.* 9, 598, 1174.—The 4-Me and 4-Et derivs. of $\text{PhCH}_2\text{C}:\text{N}:\text{NH}:\text{CO}:\text{NH}:\text{CO}:$ (A), when heated with dil. NaOH yield $\text{MeNHCONHN}:-$

$\text{C}(\text{CH}_2\text{Ph})\text{CO}_2\text{H}$ (B), m. 194° , and $\text{EtNHCONHN}:\text{C}(\text{CH}_2\text{Ph})\text{CO}_2\text{H}$ (C), m. 141° , resp. The corresponding 4- CH_2Ph deriv. of (A) under these conditions gives rise to a mixt. of phenylpyruvic acid α -benzylsemicarbazone (D), m. 168° , forming a H_2O -sol. sodium salt, and the β -isomer (E), m. 170° , giving a fairly insol. sodium salt. By treating (B) and (C) with cold concd. HCl for several days, removing with Et_2O the free $\text{PhCH}_2\text{COCO}_2\text{H}$ formed in the hydrolysis, and neutralizing the residue with Na_2CO_3 , MeNHCONHNH_2 , m. 112° , and EtNHCONHNH_2 , m. below 100° , resp., were obtained. Under these conditions, (D) and (E) yield the same 4-benzylsemicarbazide, m. 111° . All of these semicarbazides give rise to cryst. hydrochlorides and form condensation products with aldehydes and ketones.

LOUIS E. WISE.

Basic salicylates. OECHSNER DE CONINCK AND GERARD. *Compt. rend.* 160, 627-8(1915).—Just as $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ forms basic salts of bivalent metals, so the substituted salicylic acids give rise to amorphous, insol. salts of the general type $\text{XC}_6\text{H}_3\text{CO}_2\text{M}^+\text{O}^-$. The following metallic derivs. were prepd. (but the position of

the substituent group is not given): lead bromosalicylate, $\text{BrC}_6\text{H}_3\text{CO}_2\text{Pb.O.H}_2\text{O}$; lead

dibromosalicylate (without H_2O); barium chlorosalicylate (1 mol. H_2O); lead aminosalicilate (without H_2O); basic lead salicylsulfonate, $\text{HOC}_6\text{H}_3\text{SO}_3\text{Pb.O}_2\text{C.PbO}$; barium

iodosalicylate; barium diiodosalicylate; barium nitrosalicilate; copper salicylate (A), with 1 mol. H_2O , easily removed by heating at $97-8^\circ$. On heating (A) in the presence of H_2O , decompn. takes place with the formation of CuO , PhOH and CO_2 .

LOUIS E. WISE.

Saturated hydrocarbons from "vacuum tar." AMÉ PICTET AND MAURICE BOUVIER. *Compt. rend.* 160, 629-31(1915); *Ber.* 48, 926-33(1915); cf. *C. A.* 8, 414.—P. and B. in continuing their researches on "vacuum tar" (*goudron de vide*) have examd. 60 kg. of heavy oil produced by distg. under 15-20 mm. 1.5 tons of petroleum from the Montrambert (Loire) region. After removal of the unsatd. hydrocarbons by means of liquid SO_2 the following liquid cyclic hydrocarbons were isolated. They are probably homologs of cyclohexane: C_9H_{18} , b_{710} $135-7^\circ$, d_{20} 0.759, n_D^{20} 1.4212; $\text{C}_{10}\text{H}_{20}$, b_{780} $172-4^\circ$, d_{20} 0.7765, n_D^{20} 1.4196; $\text{C}_{11}\text{H}_{22}$, b_{780} $189-91^\circ$, d_{20} 0.7838, n_D^{20} 1.4234; $\text{C}_{12}\text{H}_{24}$, b_{780} $211-3^\circ$, d_{20} 0.7862, n_D^{20} 1.4293; $\text{C}_{13}\text{H}_{26}$, b_{780} $227-9^\circ$, d_{20} 0.7953, n_D^{20} 1.4379; $\text{C}_{10}\text{H}_{20}$, b_{780} $160-1^\circ$, d_{20} 0.768, n_D^{20} 1.4272. The 1st 5 of these compds. are identical with 5 hydrocarbons found by Mabery (cf. *J. Am. Chem. Soc.* 19, 470, et al) in Canadian and Californian petroleum. By distg. the heavy oil under 15 mm., $\text{C}_{10}\text{H}_{20}$ (A), needles, m. $62-3^\circ$, d_{25} 0.9128, was obtained and found to be identical with melene, obtained from beeswax by Brodie (*Ann.* 71, 156). (A) is a component of the original, undistd. oil, from which it can be isolated by extn. with boiling C_6H_6 . It is also found in the paraffin obtained from Galician petroleum.

LOUIS E. WISE.

Trimagnesium citrate and the so-called basic magnesium citrates. E. LÉGER. *Compt. rend.* 160, 660-3(1915).—A tri-Mg citrate (13 mols. H_2O) (A), square plates, was formed by satg. a concd. hot citric acid soln. with MgCO_3 . (A) crystallizes very slowly on cooling and L. assumes the formation of an intermediate hydrate containing less H_2O of hydration. When a concd. soln. of (A) is heated for 20 hrs. on a H_2O bath or at 110° , a tri-Mg citrate (9 mols. H_2O) (B), prisms, is formed. (A) loses all of its H_2O at $150-5^\circ$, whereas (B) is completely dehydrated only at 175° . By heat-

ing 3 mols. $(\text{AcO})_2\text{Mg}$ in boiling EtOH with 2 mols. citric acid a 3rd tri-Mg citrate (7 mols. H_2O) (C), sol. in 2 parts H_2O , is formed. (C) in concd. soln. is gradually converted into the less sol. (A). (C) is probably slowly formed when anhydrous tri-Mg citrate is exposed to moist air. (B) is readily sol. in NH_4OH with the formation of the compound, $\text{Mg}_3(\text{C}_6\text{H}_5\text{O}_7)_2 \cdot 2\text{NH}_4 \cdot 5\text{H}_2\text{O}$. Kammerer has previously prepd. (B) and has also described 3 basic Mg citrates (cf. *Ann.* 148, 311; 170, 181), the existence of which L. considers problematical (L. gives no analytical data in this article).

LOUIS E. WISE.

Synthesis of α -glycerophosphoric acid. O. BAILLY. *Compt. rend.* 160, 663-6 (1915); cf. *C. A.* 9, 1745.—To 18 g. of $\text{O:P(ONa)}_2(\text{OCH}_2\text{CH:CH}_2)$ (A) in 500 cc. H_2O kept at 15° were gradually added 14 g. KMnO_4 in 500 cc. H_2O . After standing for several hrs. the mixt. was filtered, neutralized, treated with 12 g. CaCl_2 in a few cc. H_2O , filtered to remove traces of $\text{Ca}_3(\text{PO}_4)_2$ and the filtrate treated with an equal vol. of EtOH, thus pptg. crude Ca α -glycerophosphate (B), which after washing with 45% EtOH, to remove chlorides, was freed from residual (A) by treating the ppt. with 49 vols. H_2O at 85° , in which (A) is nearly completely insol. From the filtrate from (B) a 25% yield of pure (B) was obtained by addition of EtOH. (B) responds to all the tests for the α -salt and is free from the β -isomer. B. gives a table of solubilities of the Ca, Sr and Ba α - and β -glycerophosphates.

LOUIS E. WISE.

Blue adsorption compounds of iodine. II and III. Derivatives of 2- and 4-pyrone. GEORGE BARGER and WALTER W. STARLING. Roy. Holloway Coll., Surrey and Goldsmith Coll., London. *J. Chem. Soc.* 107, 411-24 (1915); *Proc.* 30, 303.—A part of this work has been previously outlined (cf. *C. A.* 8, 3292; 9, 991). The additive products formed by interaction of I and synthetic compds. are either mixed crystals (solid solns.) or adsorption compds., in which case the org. compd. (amorphous or in colloidal soln.) is the adsorbent. B. and S. have traced the effect of constitution on adsorptive power and have discussed the influence of substituent groups upon adsorption. The addition of I by org. compds. is probably the result of residual affinity. In the following characterization of products prepd. by treating α -pyrones with I, M.C. = mixed crystals, A.A. = amorphous adsorption compds., and the concn. of free I at which adsorption takes place is expressed by the number of l. containing 1 g.-atom (e. g. "at 500" means "in 0.002 N I"). Unless otherwise stated, the compds. were formed by mixing the substance in EtOH with an aq. I soln. Coumarin forms M.C., blue pleochroic needles at 500; pale gray at 5000; not perfectly white at 20,000. 3,3-Dicoumaryl forms no M.C., but transitory A.A. at 100. 3-Acetylcoumarin forms M.C., gray, metallic, pleochroic plates (similar to those of coumarin) below 600, transitory A.A., blue from concd. EtOH soln. at 1000 or by rapid cooling, changing to colorless crystals in a few seconds. 3-Benzoylcoumarin (A) forms M.C. at 300, opaque, strongly pleochroic blue needles. At 100-200, 20-30% EtOH solns. of (A), on cooling, deposit large colorless needles followed by a sepn. of clusters of thin M.C. 7-Hydroxy-, 7-hydroxy-4-methyl-, 7-hydroxy-3,4-dimethyl-, 7,8-dihydroxy-, and 7,8-dihydroxy-4-methylcoumarin yield additive compds. with I only when the reactions are carried out in concd. alk. solns. (not in EtOH). Benzoates of these pyrones, in EtOH, all yield blue A.A. at 100 (with the exception of the 7,8,4-(BzO)₂Me deriv., which yields M.C., curved needles). Corresponding acetates do not react with I. The affinity of hydroxycoumarins for I may be increased by the introduction of a Ph group on the pyrone ring (e. g., 7-hydroxy-4-phenylcoumarin yields transitory A.A. at 1000). 7-Benzoyloxy-4-methyl-3,4-dihydrocoumarin does not react with I. 4,3- β -Naphthapyrone instantly yields blue A.A. at 7000, after a few min. at 10,000. H^+ has a favorable effect on this adsorption. 4,3- β -Naphthapyrone-2-carboxylic acid forms A.A. at 2000, the adsorption being markedly increased by the presence of small

amts. of CaCl_2 (and even by tap water). 4-Methyl-1,2- α -naphthapyrone forms no M.C., gives transient blue A.A. at 5000. 2-Phenyl-4,3- β -naphthapyrone gives a dark blue coloration at 1000, only on standing in the presence of H^+ or multivalent cations. The following products or colorations were obtained from γ -pyrones: 2-Phenyl-6-methylpyrone yields M.C. at 10 after 0.5 hr., the formation being favored by H^+ . 2,6-Diphenylpyrone yields A.A. up to 20,000, but no M.C. Benzo- γ -pyrone gives a crimson to purple color at 1000; its 2- CO_2H deriv. also gives a crimson coloration at 1000, as well as M.C., pleochroic needles. Na 6-methylbenzopyrone-2-carboxylate solns. give transitory A.A. up to 50, no M.C. The isomeric 7- and 8-Me derivs. behave similarly. 6,8-Dimethylbenzopyrone-2-carboxylic acid in alk. soln. at 1000-10,000 gives a crimson-purple A.A.; at <500 blue A.A. (unless an excess of KI is present). 5-Methyl-8-isopropylbenzo- γ -pyrone-2-carboxylic acid gives no blue A.A., but yields a blue amorphous substance at 10. 1,4- α -Naphthapyrone crysts. very rapidly, but shows a momentary blue coloration at 20,000. On rapid cooling a mixt. of blue flakes and colorless crystals is pptd., the latter disappearing slowly (*most* slowly in the presence of a protective colloid-like gelatin). 1,4- α -Naphthapyrone-2-carboxylic acid shows slow adsorption at 5000 from glacial AcOH , and at 20,000 from alkali. In no case did xanthone derivs. yield M.C. Xanthone forms A.A. up to 500 in neutral, up to 1000 in 0.1 *N* acid solns. 3-Hydroxyxanthone gives only a faint purple coloration at 200, in alkali. The 2-isomer has as its limits 6000 (in EtOH) and 10,000 (alkali). Similar limits were observed for 2,4- and 4,6-dihydroxyxanthenes. β -Phenonaphthaxanthone forms A.A. at 200 from neutral, at 5000 from acid solns. α -Dinaphthaxanthone, m. 240° , prepd. from $\alpha,\beta\text{-C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{H}$, forms A.A. at 20,000 and on standing, at 50,000. Flavone (*B*) gives immediate A.A. at 10-100, and M.C., blue needles, at 4000 after standing for a few min. Formation of both products is favored by H^+ . 6- and 7-Methylflavones behave similarly to (*B*); the 8-isomer forms no M.C., but gives A.A. at 1,000. All 3 isomers are 5-10 times as sensitive in *N* HCl as in neutral soln. 5-Methyl-8-isopropylflavone adsorbs very slowly, although adsorption becomes evident rather suddenly, as if after an "induction period." Multivalent cations and H^+ delay whereas multivalent anions ($\text{SO}_4^{=}$, $\text{PO}_4^{=}$, etc.) accelerate adsorption. 8-Hydroxyflavone forms no M.C., A.A. at 10 in neutral medium, transitory A.A. at 500 (H^+). 3'-Hydroxyflavone forms A.A. (from alkali) slowly at 8000. 4'-Isomer forms A.A. (from alkali) at once at 25,000. 6,4'-Dihydroxyflavone forms transitory A.A. at 1000; 5,7-isomer (chrysin), pale blue A.A. slowly at 10,000 from neutral soln., accelerated by 0.1 *N* HCl. 5,7,4'-Trihydroxyflavone (apigenin), A.A. from alkali at 2000, more slowly at 5000 (related to saponarin which forms A.A. at 4000 from alkali). 7,3',4'-Trihydroxyflavanol (fisetin) forms black A.A. from alkali at 10; green A.A. (more slowly) at 100. 2',3'-Dimethoxyflavone gives no typical I reaction. 7,3'-Diethoxyflavone forms A.A., purplish brown at 100, crimson-purple to blue at 5000, yellow to pale blue at 10,000. Both indenoflavone (*C*) and α -naphthafavone (*D*) form A.A. at very high dilns. Their color reactions with I are more sensitive than the starch-I reaction. In the presence of multivalent cations (*C*) reacts with I up to 125,000, and (*D*) gives colorations at 150,000 (on standing). Starch gives no coloration beyond 50,000 or 60,000, and is not rendered more sensitive by electrolytes. β -Naphthafavone is much less sensitive than (*D*), but gives a blue coloration at 10,000 in the presence of H^+ . Flavanones with a reduced pyrone ring are indifferent to I. Thiocoumarin at 100-1000 forms a dark-colored ppt. changing to gray crystals. Thioxanthone does not react with I. Methylthioxanthone forms black A.A. at 10, reddish brown colloidal soln. at 100. 1,4-Dimethylthioxanthone adsorbs slowly at 100 (instantaneously if CaCl_2 is present); slowly at 1000, in the presence of CaCl_2 . The 2,4-isomer forms M.C. at 100-1000. Methoxythioxanthone reacts at once at 100 (with blue coloration), more slowly at 3000, in the presence of Ca^{++} or H^+ at 10,000.

1,4-Dimethoxythioxanthone gives a green coloration at 30,000; a blue coloration if Ca^{++} is present. 2-Hydroxythioxanthone reacts up to 500; 2-methyl-(5,6,7 or 8)-monohydrothioxanthone reacts up to 10,000. 1-Hydroxy-4-ethoxythioxanthone does not react. Chloromethoxythioxanthone (cf. Marsden and Smiles, C. A. 5, 3567) and naphthathioxanthone both adsorb I up to 10,000. β -Aminonaphthathioxanthone gives a greenish coloration, up to 1000 in neutral soln., a reddish brown coloration up to 100,000 in the presence of H^+ . 3,6-Dimethylphenothioxin gives deep blue M.C. at 20. Naphthathioxin gives a reddish brown coloration which becomes bluish green on boiling (concn. of I not given), owing to a partial oxidation to the corresponding oxide, which is itself colored deep blue at 100, and yields gray M.C. at 1000. Iso-naphthathioxin oxide does not react with I, nor does naphthathioxin dioxide. Thioflavone forms M.C. at 1000. The 6-methyl deriv. reacts slowly at 5000-10,000. The 5,8- Me_2 deriv. gives A.A. at 300, but is 100 times more sensitive in the presence of H^+ (the concn. of H^+ affecting the adsorption being *much* below that affecting Congo red). The 6,8- Me_2 deriv. adsorbs at 200 in neutral, at 20,000 in acid soln. The 8-HO deriv. adsorbs only in acid up to 30. The 6-MeO deriv. reacts at 30,000 in neutral, at 50,000 in acid soln. The 8-MeO deriv. reacts at 1000 in neutral, at 5,000 in acid soln. α -Thionaphthaflavone reacts up to 100,000 in acid soln. The β -isomer is colored blue in neutral soln. at 1000, in acid soln. at 100,000. LOUIS E. WISE.

Mangostin: a crystalline substance allied to the resins. JOHN R. HILL. Inst. Med. Res., Kuala Lumpur, Federated Malay States, and Davy-Faraday Lab., London. *J. Chem. Soc.* 107, 595-601 (1915).—Mangostin (A) occurs in all parts of the mangosteen tree (*Garcinia mangostana*). The dried fruit skins contain about 5% each of a cryst. resin (A) and a non-cryst. resin. (A) was first isolated by Schmidt (*Ann.* 93, 83 (1865)), who assigned the formula $\text{C}_{20}\text{H}_{22}\text{O}_6$. (A) has the typical resin properties, burning with a smoky, luminous flame, causing friction and vibration when rubbed between the fingers, and dissolving in alkalies, alc., Et_2O , and many other solvents. (A) was obtained by concg. the alk. ext. of the dried skins *in vacuo*, shaking the syrupy residue with H_2O , and dissolving the dried insol. portion in warm PhH containing a little Et_2O . Recrystd. repeatedly from alc. containing a little H_2O , it forms flat, pale yellow needles, m. $181-2^\circ$. The analyses and mol. wt. detns. in PhOH and $(\text{CO}_2\text{Me})_2$ gave results agreeing with $\text{C}_{22}\text{H}_{24}\text{O}_6$. (A) is insol. in carbonates, dissolves in alkalies with a red color, and is reprecipitated by CO_2 and acids and gives a greenish brown color with FeCl_3 . It contains 1 MeO and 2 phenolic OH, the latter being shown by titration and by the action of Me_2SO_4 and dil. aq. KOH, which yield *dimethylmangostin*, $\text{C}_{24}\text{H}_{28}\text{O}_6$, faintly yellow, silky needles, m. 123° . (A) and warm HNO_3 gave $(\text{CO}_2\text{H})_2$, even when HOAc was used as diluent. Concd. KMnO_4 also gave $(\text{CO}_2\text{H})_2$. Fusion with 5 parts KOH at about 250° gave a volatile oil with the odor of AmOH. The aq. soln. of the fusion was acidified and extd. with Et_2O , yielding BzOH, isolated as the Ca salt. In another expt. the aq. soln. of the fusion was satd. with CO_2 , shaken out with Et_2O and then with alc., which did not mix with the soln. The alc. soln. containing K salts was evapd., acidified with H_2SO_4 , and distd. with steam. The resulting volatile acids were purified through the Ba and Na salts and finally sepd. as the Ag salts. HOAc and $\text{C}_4\text{H}_7\text{CO}_2\text{H}$ were found. Boiled with HI for 12 hrs., (A) yields a substance, $\text{C}_{22}\text{H}_{22}\text{O}_6$, faintly yellow, silky needles, m. $180-1^\circ$, changes into short rhombs with identical properties on standing overnight in the mother-liquors when crystd. from alc., gives a deep green color in alc. with FeCl_3 ; its *methyl derivative*, prepd. with Me_2SO_4 and aq. KOH containing a little alc. to facilitate soln., m. 216° ; the *monoacetyl derivative*, using Ac_2O and NaOAc, m. $218-9^\circ$. M. HEIDELBERGER.

Constitution of internal diazo-oxides (diazophenols). GILBERT T. MORGAN AND JAMES W. PORTER. Dublin. *J. Chem. Soc.* 107, 645-59 (1915).—Exception is taken

to Klemenc's characterization of these compds. as internal diazonium salts (I) (C. A. 8, 2706) and a summary of the arguments in favor of the quinopediazide (II) and *eso*-diazo-oxide (III) structures is given. Preference is given to (III), since the *peri*-diazo-oxides obtained from 1,8-HOC₁₀H₆NH₂ cannot be formulated on the basis of (II). The 2-NO₂ deriv. of (III) was prepd. (1) from 2,4-O₂N(H₂N)C₆H₃OH and NaNO₂ in dil. H₂SO₄, and (2) diazotization of 4,3-Cl(O₂N)C₆H₃NH₂ (A) followed by partial neutralization. It explodes violently at 168° and couples readily with alk. β -C₁₀H₇OH to form 3-nitro-4-hydroxybenzeneazo- β -naphthol, orange-red leaflets, m. 216°, sol. in H₂SO₄ with a crimson color. (A) is best prepd. according to Claus and Stiebel (Ber. 20, 1380

(1887)), except that the yield is made almost quant. by working at low temps. and using HNO₃ free from HNO₂. 3,4-O₂N(H₂N)C₆H₃OH (B) was obtained in finely divided form by dissolving in a warm mixt. of 2 parts HOAc and 10 H₂O and cooling; with an excess of EtNO₂ the soln. gave, on evapn. to dryness after filtering off impurities, 3-nitrobenzene-4-diazo-1-oxide, brown needles, explodes with moderate violence at 119°; also obtained from a cooled Et₂O-alc. soln. of (B) and N₂O₅ from HNO₃ and As₂O₃. With alk. *m*-C₆H₄(OH)₂ it gives 2-nitro-4-hydroxybenzeneazoresorcinol, brownish red crystals, m. 212° (decompn.). 2,5-H₂N(O₂N)C₆H₃OH was prepd. from *p*-O₂NC₆H₄NH₂ through the azoimide, at as low a temp. as possible in order to prevent tar formation. With NaNO₂ in dil. HCl it gives 5-nitrobenzene-2-diazo-1-oxide, acicular crystals or garnet prisms, darkens 95°, blackens 105°, explodes with extreme violence 111°; 4-nitro-2-hydroxybenzeneazo- β -naphthol, bright red, sepd. from soln. as the monopotassium salt, green crystals with a bronze luster, explodes on heating; a table is given of the intensely colored salts of the dye with a no. of other metals. If *m*-H₂NC₆H₄OH is dissolved in warm Ac₂O and the soln. allowed to cool, *m*-AcNHC₆H₄OH is obtained. This, added slowly with stirring and cooling with ice-salt to 6 parts HNO₃ (d. 1.4), gave a mixt. (80% of the theory) of the 4- and 6-NO₂ derivs. easily sepd. through the sparing solubility of the 4-compd. in alc. Diazo-oxides could not be prepd. from these, but the diazonium salts were characterized by the prepn. of azo derivs. which sepd. as sparingly sol. alk. salts and were liberated by mineral acids. 4-Nitro-3-hydroxybenzeneazoresorcinol, dark red crystals, m. 196°; 2-nitro-5-hydroxybenzeneazo- β naphthol, red, does not m. below 260°; 4,6,3-(O₂N)₂(H₂N)C₆H₃OH, diazotized with EtNO₂, gave 2,4-dinitro-5-hydroxybenzeneazo- β -naphthol, brown-red needles, does not m. below 260°.

M. HEIDELBERGER.

Method for distinguishing tautomeric, isomeric, and polymeric from polymorphic substances. NEVIL V. SIDGWICK. Oxford. *J. Chem. Soc.* 107, 672-8(1915).—"Let *A* be the more sol. of the 2 forms *A* and *B*. A satd. soln. of *A* is made in a suitable solvent, and to this (at const. temp.) is added some solid *B*. If the forms are polymorphic, and both give the same mols. in soln., then since the soln. is satd. with *A*, which is the more sol. form, *B* will not dissolve. . . . At any rate, the concn. of the soln. will not increase." If, however, the forms are tautomeric, isomeric, or polymeric, "then *A* and *B* will each dissolve as such. . . (if the tautomeric change is not too rapid) and the soln. will become stronger. . . ." The simplest way of following the change in concn. is by the f. p. method. In this way, using PhH as solvent, it is shown, among other examples, that the 2 forms of *p*-O₂NC₆H₄OH, *p*-BrC₆H₄NHAc, and 2,4-C₆H₃-

NHAc are polymorphic, those of benzoylcamphor tautomeric (enol and ketone), that *d*- and *l*-camphoric anhydrides are isomeric and that the 2 forms of BzCH:NNHPh are tautomeric.

M. HEIDELBERGER.

Formaldehyde salts. H. FRANZEN AND L. HAUCK. Karlsruhe. *J. prakt. Chem.* 91, 261-84 (1915); cf. *C. A.* 8, 3423.—Several metallic salts of CH_2O were prepd. and studied with regard to the possibility that they may be intermediate compds. in the polymerization of CH_2O to sugar. Their suggested structural formulas and manner of formation is illustrated in the case of the Ca salt, *e. g.*, $2\text{CH}_2(\text{OH})_2 + \text{Ca}(\text{OH})_2 = \text{Ca}(\text{OCH}_2\text{OH})_2 + 2\text{H}_2\text{O}$. The length of the chain in these compds. varies with the different metals. When very dil. solns. of CH_2O with $\text{Ca}(\text{OH})_2$ are used, it is suggested that a salt of the comp. $\text{HOCH}_2\text{OCaOH}$ (a) is formed, and that in the formation of sugars from CH_2O 2 mols. of (a) condense with elimination of $\text{Ca}(\text{OH})_2$ to form $\text{HOCH}_2\text{CH}(\text{OH})\text{OCaOH}$, which similarly condenses with another mol. of (a) to form the $\text{HOCH}_2\text{CH}(\text{OH})\text{CHO}$ deriv., and that this product finally in the same way yields the hexose. The lead salt, $\text{CH}_2[(\text{OPbOCH}_2)_2\text{OPbOH}]_2 \cdot 2\text{H}_2\text{O}$, prepd. by shaking for 24 hrs. in 650 cc. H_2O , 72 g. of 40% CH_2O with the $\text{Pb}(\text{OH})_2$ obtained from 113.6 g. $\text{Pb}(\text{OAc})_2$ and 24 g. NaOH , and drying *in vacuo* over KOH and H_2SO_4 , was obtained as a white powder having a strong odor of CH_2O . It gives a clear soln. with cold, dil. HNO_3 and AcOH . On standing in the dark in a closed flask for 8 weeks, its CH_2O content fell from 9.42 to 6.37%, and when heated at 140° it was gradually converted into another form with very little evolution of free CH_2O . Calcium salt, similarly prepd., shows the same properties as the Pb salt. It is decompd. by both alc. and H_2O . Strontium salt, $\text{CH}_2(\text{OSrOCH}_2\text{OH})_2 \cdot 7\text{H}_2\text{O}$, white powder, decomp. on standing, forming a brown substance having the odor of caramel. An attempt to prep. the barium salt in the same way gave a product which after standing *in vacuo* for 2-3 days over KOH and H_2SO_4 decompd. vigorously, giving a yellowish brown liquid having the odor of burned sugar. The following salts were also prepd.: magnesium salt, from MgO and CH_2O , white powder; zinc salt, $\text{CH}_2(\text{OZnOH})_2 \cdot 2\text{H}_2\text{O}$, by shaking 12 g. NaOH in 50 cc. H_2O + 18 g. of 40% CH_2O with 43 g. ZnSO_4 in 100 cc. H_2O , white powder, sol. in dil. acids; cadmium salt, $\text{CH}_2[(\text{OCdOCH}_2)_2\text{OCdOH}]_2 \cdot 9\text{H}_2\text{O}$, prepd. like the Zn salt, white powder; copper salt, $\text{Cu}(\text{OCH}_2\text{OCuOCH}_2\text{OH})_2 \cdot 2\text{H}_2\text{O}$, green powder. Attempts to prep. the Al, Fe, Ni and Na salts were unsuccessful. D. BRESE JONES.

Nitrotolylglycine. W. POLLAK. Vienna. *J. prakt. Chem.* 91, 285-306 (1915).— $\text{BrCH}_2\text{CO}_2\text{H}$ reacts readily with 2,4- and 2,6- $\text{H}_2\text{N}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Me}$ with the formation of the corresponding glycine derivs., but there is practically no reaction when $\text{ClCH}_2\text{CO}_2\text{H}$ is used. 2,4- $\text{O}_2\text{N}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{Me}$ with the above AcOH derivs. yielded mere traces of the glycine derivs. The reaction is expressed by the following equations: $3\text{C}_7\text{H}_6(\text{NO}_2)\text{NH}_2 + \text{BrCH}_2\text{CO}_2\text{H} = \text{CH}_2(\text{NHC}_7\text{H}_4\text{NO}_2)\text{COH} \cdot \text{C}_7\text{H}_6(\text{NO}_2)\text{NH}_2$ (a) + $\text{C}_7\text{H}_6(\text{NO}_2)\text{NH}_2 \cdot \text{HBr}$; (a) + $\text{NaOH} = \text{CH}_2(\text{NHC}_7\text{H}_4\text{NO}_2)\text{CO}_2\text{Na} + \text{C}_7\text{H}_6(\text{NO}_2)\text{NH}_2 + \text{H}_2\text{O}$. These glycine derivs. have strong acidic properties, dissolving readily in alkali carbonates. The following derivs. of 2,4- $\text{H}_2\text{N}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Me}$ were prepd.: on slowly heating 3 mols. amine with $\text{BrCH}_2\text{CO}_2\text{H}$ up to 90° , the fused product suddenly solidified, at the same time changing from reddish to yellowish brown. Further heating for 3 hrs., then boiling with H_2O , making alk. with NaOH , filtering off the $\text{H}_2\text{N}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Me}$ and acidifying the filtrate with dil. HCl , gave 1,2,4-nitrotolylglycine (b) in 85% yield, lustrous, yellow needles from H_2O , m. 140° ; silver salt, small needles, unstable in the air; copper salt, $[\text{C}_7\text{H}_6(\text{NO}_2)\text{NHCH}_2\text{CO}_2]_3\text{Cu} \cdot \text{H}_2\text{O}$, beautiful green crystals, m. 195° ; methyl ester, from the Ag salt and MeI , yellow needles, m. 108° ; ethyl ester, from alc. HCl , reddish brown needles, m. 42° ; 1,2,4-aminotolylglycine hydrochloride, by reducing (b) with Zn dust and HCl , brown crystals from alc., m. 98° . Diazotized and coupled with alc. β -naphthol it gave a dye, and also a reddish brown dye with "R" salt; on heating for 4-5 hrs.

at 150–60°, (b) gave 1,2,4-dinitroditolyl- α,γ -diacipiperazine, bright yellow compd. by pptg. from AcOH with H₂O, m. 186°, insol. in alkalis. It is decompd. into its components by boiling with alc. KOH. In a similar way the following derivs. of 4,2-H₂N-(O₂N)C₆H₄Me were prepd.: 1,4,2-Nitrotolylglycine, yellow prisms from alc., m. 130°; ammonium salt, reddish brown prisms, m. 135°, which with (AcO)₂Pb forms the lead salt, microscopic orange needles; copper salt + H₂O, green crystals, m. 160°. From 2,6-H₂N(O₂N)C₆H₄Me the following derivs. were obtained: 1,2,6-Nitrotolylglycine, yellowish brown prisms from alc., m. 152°; silver salt, very unstable; lead salt + H₂O, grayish yellow compd., m. 170°. Somewhat similarly, 2,5- and 3,6-H₂N(O₂N)C₆H₄Me gave the following derivs.: 1,2,5-Nitrotolylglycine (c), reddish brown crystals from alc., m. 192°; on heating it does not yield a piperazine deriv.; lead salt, yellow compd.; barium salt + 0.5 H₂O, from the acid + BaCO₃, yellowish brown needles; NaNO₂ gives with (c) in dil. HCl the nitroso derivative, C₇H₆(NO₂)N(NO)CH₂CO₂H, m. 110°; ethyl ester, from 2 mols. 2,5-H₂N(O₂N)C₆H₄Me and ClCH₂CO₂Et at 130–40° for 2 days, also by esterifying (c) with HCl, crystals from C₆H₆, m. 87°; methyl ester, from the Ag salt and MeI, yellow needles from C₆H₆, m. 82°; 1,3,6-nitrotolylglycine, yellow crystals from H₂O, m. 145°. It gives colored, cryst., salts with most of the bases. D. B. J.

β -Naphthol sulfide and iso- β -naphthol sulfide. II. O. HINSBERG. Freiberg. *J. prakt. Chem.* 91, 307–24(1915); cf. *C. A.* 9, 209.—A continuation of the study of the properties and isomerism of β -naphthol sulfide (a) with iso- β -naphthol sulfide (b). With warm NaOH (a) decomp. with loss of CO₂, while (b) is hardly affected. Na₂S converts the red oxidation product (c) of (a) (formerly called dehydronaphthol sulfide) into (b). On boiling with 7–10% NaOH (b) is converted into (a), but if a trace of Na₂S is present the transformation is prevented. By dissolving (b) + β -C₁₀H₇SO₂Cl in C₆H₄N, and allowing the soln. to stand for several days, di- β -naphthosulfone-iso- β -naphthol sulfide, (C₁₀H₆OSO₂C₁₀H₇)₂S, was obtained as crystals from AcOH, m. 110° (decompn.). Yellow needles of β -naphthol disulfide, m. 171°, were obtained by reducing the sulfoxide (d), (HOC₁₀H₆)₂SO, with Zn and AcOH. It is assumed that the disulfide is formed by atm. oxidation of the intermediate reduction product α,β -C₁₀H₆(SH)OH. On warming (d) for a short time with HI (d. 1.96) it is nearly quant. decompd. into SO₂ and β -C₁₀H₇OH, and when allowed to stand in a closed vessel for 6 days with MeOH satd. with HCl it likewise gave β -C₁₀H₇OH and SOCl₂. The product obtained by Henriques (cf. *Ber.* 27, 2993 (1984)) by the action of H₂NNHPh on (c) is not, as he reported, a di-, but a monophenylhydrazone. H. has now further obtained a mono-*p*-nitrophenylhydrazone, red needles from AcOH, m. 207°, which with concd. H₂SO₄ gives a green color, changing to violet on warming. Therefore, (c) has only 1 CO, and its structure is represented by the formula O:C₁₀H₆:S.C₁₀H₆.O, to which

the name iso- β -naphtholsulfonium anhydride is assigned. Semicarbaside, brownish red crystals from MeOH, decomp. 115°. On standing for several days at room temp. with MeOH satd. with HCl, (c) is converted into a yellow powder identical with Christopher and Smiles' chloronaphthioxin (*C. A.* 6, 3265). (c) is unaffected by HClO₄. By adding 1 mol of 30% H₂O₂ in AcOH to (b) in acetone, and allowing the mixt. to stand for 12 hrs., a quinkhydrone derivative + CHCl₃ (e) was obtained as yellow needles from petr. ether + CHCl₃, m. 141° (decompn.). It can be obtained free from CHCl₃ by pptg. from acetone with H₂O. It then m. 143° (decompn.). Heated to const. wt. at 130–40° it yielded (b), (c) and some (e). A similar decompn. occurs when it is boiled for a few min. with 5% NaOH. When oxidized with H₂O₂ + AcOH it gave a compound, yellow leaves from AcOH, m. 70–80°. A further study of the properties of dehydro- β -naphtholsulfone (f) confirms the constitution previously assigned to it, C₁₀H₆.O.O.C₁₀H₆.SO₂. It yields no phenylhydrazones or oximes. On reduction

with Zn and AcOH it gives in 70–80% yield a β -dinaphthol, fine needles from petr. ether + CHCl_3 , m. 197° . This compd. differs essentially from the known dinaphthol obtained by oxidation of β - $\text{C}_{10}\text{H}_7\text{OH}$, which m. 216° , but it may be identical with Kauffmann's dinaphthol, m. 195° (Ber. 15, 807 (1882)). By boiling for 10 mins. with Ac_2O and AcONa the dinaphthol gave a *diacetate*, hair-like needles from alc., m. 113° . On reduction, either with Zn + MeOH + NH_4OH , or with Na_2S in MeOH, (f) yields *iso- β -naphthol sulfone* (g), $(\text{HOC}_{10}\text{H}_6)\text{SO}_2$, white, amorphous powder, becomes yellow and sinters 85° , m. to a thick fluid 110° and a thin liquid 125° . With alk. $\text{PhN}:\text{NCl}$ it gives a colorless soln. (the isomeric naphthol sulfone gives a yellowish red ppt.). When oxidized with $\text{K}_3\text{Fe}(\text{CN})_6$ it gave (f). On heating at 100° , or by the action of AcOH, Ac_2O and HCO_2H (g) loses 1 mol. H_2O , forming an *anhydride*, to which is assigned the constitution, $\text{O}:\text{C}_{10}\text{H}_6:\text{SO}:\text{C}_{10}\text{H}_6\text{O}$, because of its similarity to (c) in giving with

AcCl isodichloronaphthioxin, yellow crystals, m. 234° . With $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ it gave a *dihydrazone*.
D. BRÉESE JONES.

Methenyldiphenylhydrazine. M. BUSCH AND W. DIETZ. Univ. Erlangen. J. prakt. Chem. 91, 325–9 (1915).—That the various m. ps. which have been given to methenyldiphenylhydrazine (a) may be due to the structure isomerism, $\text{Ph}(\text{NH}_2)\text{NCH}:\text{NPh}$ (b) and $\text{PhNHNHCH}:\text{NPh}$ (c), led B. and D. to a further study of its properties and constitution. Only 1 product, pale yellow leaves, m. 109.5° , was always obtained by several different methods of prepn. (cf. Walther, J. prakt. Chem. 53, 473; 57, 223; Dains. Ber. 35, 2503; Schmidt, Ber. 36, 2481). The following method of prepn. and reactions show that (c) represents its true structure. A mixt. of 2 mols. P_2O_5 with PhNH_2 + PhNHNHCHO in C_6H_6 was warmed on a H_2O bath for 1 hr. After distg. off the C_6H_6 , washing with H_2O , and neutralizing with NH_4OH , a poor yield of (a) was obtained. It yields on oxidation in C_6H_6 with HgO *benzenesomethananil*, $\text{PhN}:\text{NCH}:\text{NPh}$, red, stout, radiating needles, m. $62\text{--}3^\circ$, which on standing for 1–2 days decmps., leaving a brown, tarry residue. It is also decmpd. by alc., with evolution of gas and formation of methenyldiphenylamidine. The main reaction obtained by warming equimol. amts. of (a) with BzH is expressed by the equation: $\text{PhNHN}:\text{CHNPh} + \text{BzH} = \text{PhNHN}:\text{CHPh} + \text{PhNHCHO}$. This is also accompanied by the reaction: $\text{PhNHNHCH}:\text{NPh} + \text{BzH} = \text{PhNHNHCHO} + \text{PhCH}:\text{NPh}$.

D. BRÉESE JONES.

Preparation of picrates from alkylpyridinium and analogous bases. R. F. VON WALTHER. Dresden. J. prakt. Chem. 91, 329–31 (1915).— $\text{C}_4\text{H}_5\text{N}$ reacts readily with Et picrate on warming, with formation of *ethylpyridinium picrate*, $\text{C}_4\text{H}_5(\text{NO}_2)_3\text{N}(\text{OEt})\text{C}_6\text{H}_3$, yellow leaves from abs. alc., m. 91° . It is decmpd. by boiling H_2O , and by dil. HCl . It can also be prepd. by heating a mixt. of pyridine picrate with $\text{HC}(\text{OEt})_3$ for 1 hr. at $130\text{--}40^\circ$. In a similar way quinoline gave *ethylquinolinium picrate*, yellow leaves from abs. alc., m. 151° , unstable toward dil. mineral acids and dil. alkalies.

D. BRÉESE JONES.

Hydrazones of cyclohexylhydrazine. N. KIZHNER. J. Russ. Phys. Chem. Soc. 46, 1409–11 (1914).—With a view of examg. the behavior of cyclohexylhydrazine (a) with sugars, it was made to react with glucose, fructose, arabinose, mannose (b) and rhamnose (c). It was found that in no case could compds. of the osazone type be obtained, the tendency of (a) to form hydrazones being far less pronounced than that of PhNHNH_2 , only (b) and (c) giving such compds. *Mannose cyclohexylhydrazosone*, $\text{C}_6\text{H}_{11}\text{O}_4:\text{NNHC}_6\text{H}_{11}$ (possibly with 1 mol. of H_2O), needles, m. 143° , $[\alpha]_D^{25} 2.65^\circ$. *Rhamnose cyclohexylhydrazosone*, $\text{C}_6\text{H}_{11}\text{O}_4:\text{NNHC}_6\text{H}_{11}$, needles, m. $123\text{--}4^\circ$, $[\alpha]_D^{25} 7.37^\circ$. The formation of these cryst. compds. may be utilized for sepg. (b) or (c) from their mixts. with the other 3 of the above sugars.

H. M. GORDIN.

Synthesis of 2-methyl- β -hydrindone by the action of α -bromisobutyryl bromide on benzene in presence of aluminium chloride. N. KIZENER. *J. Russ. Phys. Chem. Soc.* 46, 1411-27 (1914).—With the object of prepg. the unsatd. ketone BzCMe:CH_2 (a), $\text{Me}_2\text{CBrCOBr}$ was made to react with C_6H_6 in presence of AlCl_3 . It was expected that the product of the reaction would be the bromo ketone BzCBrMe_2 (b), and that this, by treatment with alc. KOH, would yield (a). While (b) was not isolated, its formation was proved by a detn. of the amt. of HBr produced. But the interaction of (b) with KOH gave such an insignificant amt. of (a) that the latter could not be isolated in pure condition, while the chief reaction product was β -methyl- α -hydrindone (c) (yield, 60%). That some (a) was formed in the reaction was proved by the fact that the higher fractions from which most of the (c) had been removed gave upon bromination and subsequent treatment with alkalis CHBr_3 , BzOH and a cryst. compound, $\text{C}_{20}\text{H}_{22}\text{O}_2$ (d), m. 190° . (d) is not affected by boiling Ac_2O , Br, PhNHNH_2 , or concd. NH_3 at 210° . Its formation from (a) is due to the action of H_2O : $2\text{C}_{10}\text{H}_{10}\text{O} + \text{H}_2\text{O} = \text{C}_{20}\text{H}_{22}\text{O}_2$. With fuming HNO_3 (d) interacts to form a dinitro compound, $\text{C}_{10}\text{H}_{10}(\text{NO}_2)_2\text{O}_2$, m. 64° , whose formation is supposed to be preceded by hydration: $\text{C}_{10}\text{H}_{22}\text{O}_2 + \text{H}_2\text{O} = 2\text{C}_{10}\text{H}_{12}\text{O}_2$. This compd. is then nitrated by the HNO_3 . The unexpected formation of (c) may be due either to an isomerization of (b), under the influence of AlCl_3 , to $\text{BzCHMeCH}_2\text{Br}$ which then loses HBr and changes to (c), or to a direct isomerization of (a) to (c) caused by the alc. KOH, or it may be accounted for by assuming the intermediate formation of $\text{C}_6\text{H}_4\text{CO.CMe}_2$, which, owing to the instability of 4-mem-

bered rings, isomerizes to (c). (c) is a liquid of a BzMe odor, b_{710} 249° , b_m 136° , d_4^{20} 1.064, n_D^{20} 1.5543; sol. in concd. HBr with a red color; diln. of this soln. with a little H_2O ppts. an unstable hydrobromide, $\text{C}_{10}\text{H}_{10}\text{O.HBr}$, which upon the addition of much H_2O decomps. with regeneration of (c). The semicarbazone, m. 198° , the oxime, m. $105-6^\circ$, and the amine of (c) (Kipping, *J. Chem. Soc.* 83, 913) were prepd. The latter had d_4^{20} 0.9939, n_D 1.541. The hydrazone of (c), made by acting on the latter with $\text{N}_2\text{H}_4\text{H}_2\text{O}$, m. 72° , b_{14} 166° , is decompd. by boiling dil. H_2SO_4 with regeneration of (c). By reducing (c) with Na in alc. was obtained β -methyl- α -hydrindol, $\text{C}_6\text{H}_4\text{CH}_2\text{CHMe.CHOH}$ (e), b_{760} 243° , becomes partly cryst. on standing; it is most

probably a mixt. of *cis* and *trans* isomers. Upon reduction of (e) with HI at 210° was obtained β -methylhydrindene, b_{717} $183-5^\circ$, d_4^{17} 0.9034, n_D 1.507, is not affected by KMnO_4 , but vigorously reacts with fuming HNO_3 , giving NO_2 compds. Upon bromination (c) gave β -bromo- β -methyl- α -hydrindone, $\text{C}_6\text{H}_4\text{CH}_2\text{CBrMe.CO}$ (f) (yield, 95%), m.

$71-2^\circ$. Reduction with the Cu-Zn couple in presence of a trace of PtCl_4 reconverted (f) into (c). In absence of Na_2CO_3 (f) is not affected by KMnO_4 , while in presence of Na_2CO_3 it goes into soln. and is then oxidized by KMnO_4 to $\alpha\text{-C}_6\text{H}_4(\text{CO}_2\text{H})_2$. If alkali be added to a trace of (f) in alc. and the soln. evapd. to dryness, a black residue remains which dissolves in H_2O with an intense indigo-blue color. The color disappears upon addition of acids. From the acid soln. Et_2O exts. an oily substance which dissolves in alkali with blue color. The blue soln. oxidizes on exposure to the air, the color changing to green and finally to yellow. The absorption spectrum of the blue liquid resembles that of solns. of indigosulfonic acid. With $p\text{-BrC}_6\text{H}_4\text{NHNH}_2$ (f) gives the compound $\text{C}_{10}\text{H}_8\text{:NNHC}_6\text{H}_4\text{Br}$, transparent prisms of the color of $\text{K}_3\text{Fe}(\text{CN})_6$, m. $122-3^\circ$. The constitution of this compd., assuming that no condensation took place, is either $\text{C}_6\text{H}_4\text{CH}_2\text{C}(\text{:CH}_3)\text{:NNHC}_6\text{H}_4\text{Br}$ or $\text{C}_6\text{H}_4\text{CH:CMe.C:NNHC}_6\text{H}_4\text{Br}$.

When boiled with K_2CO_3 (f) yields β -methyl- β -hydroxy- α -hydrindone (yield, 70%), m. 57° , dissolves in alkalis with formation of salts; evapd. with alc. alkalis it gives the blue color reaction of (f); semicarbazone, m. 169° .

H. M. GORDIN.

Velocity of hydrogenation of tetramethylbutindiol in presence of colloidal palladium under different conditions. YU. S. ZAL'KIND AND P. V. PISHCHIKOV. *J. Russ. Phys. Chem. Soc.* 46, 1527-39(1914).—In a former investigation (*C. A.* 8, 1419) it was established that, in presence of colloidal Pd, acetylene glycols readily unite with 2 atoms of H, changing to ethylene glycols, while the further addition of H, if it takes place at all, is considerably slower. In the present work an exam. was made of the influence of temp. concn. of catalyzer, concn. of reacting glycol, and nature of solvent on the velocity of the reaction. As glycol tetramethylbutindiol (a) was taken, while as solvents only EtOH, MeOH and H₂O could be used, the reaction in other solvents (acetone, iso-BuOH and iso-AmOH) being too slow. By varying each of the above factors at a time the following results were obtained: The usual equation for calcg. the velocity const. of a monomol. reaction was found inapplicable in this case, the value of this const. gradually increasing with the length of time the hydrogenation is permitted to go on. This is supposed to be due to (a) itself acting as a negative catalyzer. With the gradual disappearance of (a) its retarding influence on the velocity diminishes, thus causing the const. gradually to increase. If the catalytic influence of (a) be taken into consideration we must use Henri's equation (*Z. physik. Chem.* 39, 194): $1/t \times \log [(a+x)/(a-x)] = k(1+ex)$, in which k is the velocity const. of the reaction, e the const. characterizing the catalytic effect of (a), a the initial concn. of (a), and $a-x$ its concn. at the time t . If $e = 2$, H.'s equation fits the reaction under consideration. The value of k was found to be an almost linear function of the temp. Between 10-20° the increase in the value of k per 1° is 0.0021, and the ratio of k at 20° to k at 10° is 1.75. This rather large value is characteristic of chem. action, showing that in the hydrogenation of (a) chem. factors are paramount. Increasing the concn. of the catalyzer also causes k to increase, but while with low concns. of catalyzer (up to 1 mg.) k grows faster than this concn.; for high concns. of catalyzer k is almost proportional to this concn. With respect to the concn. of (a), it was found that with alc. as solvent there is a definite optimum of concn. when k is a max., and that the increase of k caused by increasing the concn. of the catalyzer is less in dil. than in concd. solns. As to the influence of the solvent, k is greatest in MeOH and smallest in H₂O, showing that the solvent too has a catalytic effect. The retarding influence of (a) on the velocity of the reaction was proved by a series of expts. in which additional quantities of it checked the increase of k , in some cases causing the latter to remain const. for 10 min., and then even gradually to decrease. Whether other acetylene glycols exercise a similar retarding influence on k will be examd. later. Numerous tables and several diagrams illustrate the work. H. M. GORDIN.

Action of nitric acid on saturated compounds. S. S. NAMEYKIN AND A. K. RUZHENTSOVA. *J. Russ. Phys. Chem. Soc.* 46, 1540-4(1914).—In a previous article (*C. A.* 5, 3246) it was shown that cyclohexylnitromethane, C₆H₁₁CH₂NO₂ (a), when oxidized with HNO₃, yields as chief product adipic acid (b), and that 2 explanations of the reaction were possible: either (a) is first converted into C₆H₁₁CO₂H (c), or the oxidation is direct without the intermediate formation of (c). In order to decide between these 2 points of view, the acids (c), cyclopentylcarboxylic (d) and cyclobutylcarboxylic were oxidized with HNO₃. It was found that in these cases no trace of dibasic acid (adipic or glutaric) was produced. Hence the 1st explanation cannot be correct. On the other hand, the oxidation of C₆H₁₁CH₂OH and C₆H₁₁CHO gave (b), while cyclopentylcarbinol, cyclobutylcarbinol and the aldehyde corresponding to (d) gave glutaric acid, which is in accord with the 2nd explanation. H. M. GORDIN.

Polymembered rings in the copper salts of bisimino acids. N. A. SHLEZINGER. *J. Russ. Phys. Chem. Soc.* 46, 1575-9(1914).—Detns. of the mol. wt. by the f. p. method and of the elec. cond. of Cu ethylenebis- α -iminopropionate (I) and ethylenebis- α

iminoisobutyrate (II) (cf. following abstr.) showed them to be completely un-ionized. Hence they must be regarded as inner salts whose formulas contain 11-membered

rings. Since in accord with Bayer's strain theory only 4- and 5-membered rings are characterized by great stability, the exceptional stability of these salts must be ascribed to the influence of the divalent Cu.
H. M. GORDIN.

Ethylenebis- α -imino acids. N. A. SHLEZINGER. *J. Russ. Phys. Chem. Soc.* 46, 1579-97 (1914).—The new acids here described were synthesized from the corresponding nitriles made by Zelinskii and Stadnikov's method (*Ber.* 39, 1722), substituting $(\text{CH}_2\text{NH}_2)_2 \cdot 2\text{HCl}$ for $\text{NH}_4\text{Cl} : (\text{CH}_2\text{NH}_2)_2 \cdot 2\text{HCl} + 2\text{KCN} + \text{R}_2\text{CO} = [\text{CH}_2\text{NHC}(\text{CN})\text{R}]_2 + 2\text{KCl} + 2\text{H}_2\text{O}$. The sapon. of these nitriles presented considerable difficulty, the usual methods of sapon. decomp. them into HCN , $(\text{CH}_2\text{NH}_2)_2$ and aldehydes. Only the nitrile from Me_2CO is readily saponifiable, most of the others requiring concd. H_2SO_4 for sapon., while some could not be sapon. at all. The free acids obtained from the nitriles are completely insol. in neutral solvents, but dissolve in acids or alkalis. No Ni and Co salts of these acids could be obtained, but their Cu salts were made by boiling them with $\text{Cu}(\text{OH})_2$. Their esters are comparatively stable (during 3 months), and require prolonged boiling with H_2O or acid for sapon. The refraction of the esters is normal. The above equation indicates the materials from which the following compds. were made: *Ethylenebis-[α -iminoisobutyric] acid*, $[\text{CH}_2\text{NHC}(\text{CO}_2\text{H})\text{Me}]_2$, powder, does not m. 245° ; *hydrochloride*, $\text{C}_{10}\text{H}_{10}\text{N}_4\text{O}_4 \cdot 2\text{HCl}$, glittering needles, does not m. 245° ; *copper salt*, $\text{C}_{10}\text{H}_{10}\text{N}_4\text{O}_4\text{Cu}$, blue crystals, sol. in H_2O , is a non-electrolyte, and has normal mol. wt. (detd. by the f. p. method; cf. preceding abstr.); *methyl ester*, m. $39-40^\circ$, b_{18} 170° , volatile when warmed, and has a basic odor; *hydrochloride* of this ester, $\text{C}_{12}\text{H}_{14}\text{N}_4\text{O}_4 \cdot 2\text{HCl}$; *ethyl ester*, oily liquid of a peculiar odor, b_{18} $171-2^\circ$, d_4^{20} 0.9934, n_D^{20} 1.4432, gives a cryst. *hydrochloride*. *Nitrile*, transparent, oblique plates, m. $55-6^\circ$; *hydrochloride*, $\text{C}_{10}\text{H}_{10}\text{N}_4 \cdot 2\text{HCl}$, snow-white crystals, m. $93-4^\circ$ (decompn.). *Ethylenebis-[α -iminopropionic] nitrile hydrochloride*, $[\text{CH}_2\text{NHC}(\text{CN})\text{Me}]_2 \cdot 2\text{HCl}$. The acid is indistinctly cryst., m. about 262° (decompn.); *hydrochloride*, needles, m. (not sharply) 214° (in a capillary); *copper salt*, resembles the preceding Cu salt; *ethyl ester*, mobile liquid of a feeble, basic odor, b_{18} 170° , d_4^{20} 1.0297, n_D^{20} 1.4483. *Ethylenebis-[α -iminodactylic] acid*, not quite pure; *hydrochloride*; *nitrile hydrochloride*; *amide*, m. $175.6-6.6^\circ$; *amide hydrochloride*. *Ethylenebis-[α -iminophenylacetic] acid*, does not m. 250° ; *hydrochloride*, glittering needles; *copper salt*; *methyl ester*, non-volatile, very viscous, yellowish liquid, d_4^{20} 1.1501, n_D^{20} 1.5448; *ethyl ester*, resembles the preceding Me ester, d_4^{20} 1.1091, n_D^{20} 1.532; *ethyl ester hydrochloride*. *Nitrile*, m. $122-3^\circ$; *hydrochloride*, has no definite m. p., decomp. in a capillary $148-54^\circ$. *Ethylenebis-[α -imino- α -phenylpropionic] acid*, amorphous, turns yellow 155° ; *hydrochloride*; *copper salt*; *nitrile*, oblique plates, m. $108-9^\circ$. *Ethylenebis-[α -imino- α , α -diphenylacetic] nitrile*, m. $158-63^\circ$ (decompn.), could not be sapon. to the corresponding acid. *Piperazine-2,3-diphenyl-2,3-dicarboxylic nitrile*, $\text{PhC}(\text{CN})\text{NH}.\text{CH}_2\text{CH}_2\text{NH}.\text{C}(\text{CN})\text{Ph}$, m. 123° (decompn.); unites with EtOH to

form the cryst. compound $\text{C}_{18}\text{H}_{18}\text{N}_4.\text{EtOH}$, m. $248-9^\circ$, and with MeOH to form the cryst. compound $\text{C}_{18}\text{H}_{18}\text{N}_4.\text{MeOH}$. The acid corresponding to this nitrile could be obtained only as *hydrochloride*, $\text{C}_{18}\text{H}_{18}\text{N}_4\text{O}_4 \cdot 2\text{HCl}$, and as a blue *copper salt*. The *nitrile*

method from 1,4-cyclohexanedione, decomps. 110° The acid corresponding to it could not be prepd.

H. M. GORDIN.

Color of mixtures of anilines with aromatic nitro compounds. E. V. BIRON AND O. M. MORGULEVA. *J. Russ. Phys. Chem. Soc.* 46, 1598–613 (1914).—While PhNH_2 is colorless and PhNO_2 only slightly yellowish, mixts. of them are intensely colored. With a view of detg. the reason thereof, 17 mixts. of 7 different anilines with PhNO_2 and with *o*- and *m*- $\text{MeC}_6\text{H}_4\text{NO}_2$ were examd. colorimetrically and spectroscopically. The changes in the absorption spectra and in the intensity of coloration as found experimentally, were plotted against the changes in the mol. concns. of the anilines, and the results compared with the values obtained from the equation of the theoretical curve: $J = 4x(1 - x)$, in which J is the mol. intensity of color, and x the fraction of the anilines per mol. of mixt. The equation is based upon the assumption that the intensities of color are proportional to the masses x and $1 - x$ of the components, making $J = 1$ when $x = 0.5$. The exptl. values of J are $J = iV$, where i is the observed intensity of color for any given mixt., and V is the mol. vol. of this mixt. at 20° . The results showed that the observed changes in J corresponding to changes in x did not coincide with the locus of the theoretical curve. Hence Ostromuiskii's assumption that the color is due to the formation of definite compds. consisting of 1 mol. each of aniline and a NO_2 compd. ("Theory of the Benzene Ring and the Ethylene Union," 1910, 58) cannot be correct. That there is some relation between the color of a mixt. of aniline with a NO_2 compd. and the concn. of the former in the mixt. is clear, but the law of this relation is at present unknown. The mixts. of PhNO_2 have a more intense color than those of *o*- $\text{MeC}_6\text{H}_4\text{NO}_2$, while those of *m*- $\text{MeC}_6\text{H}_4\text{NO}_2$ occupy an intermediate position. The intensity of color also varied with the nature of the aniline, some giving intensely colored mixts., while others gave mixts. whose color varied within wide limits.

H. M. GORDIN.

Article of E. V. Biron and O. M. Morguleva. (Color of mixtures of anilines with aromatic nitro compounds.) E. I. ORLOV. *J. Russ. Phys. Chem. Soc.* 47, 185–90 (1915).—The failure of Biron and Morguleva (preceding abstr.) to correlate their exptl. data with the theoretical values is due to the use of an equation which does not take into consideration the possibility of formation of intermediate products whose nature and amt. vary with the concn. x of the anilines. With the equation: $J = 4mx(1 - mx)$, the agreement between expt. and theory is very much improved. The coeff. m indicates the velocity const. due to the intermediate reactions for any given value of x . Since when $J = 1$, $mx = 0.5$, the value of m for any value of x is $m = 0.5/x$. Some of B. and M.'s tables are recalcd. on the basis of this equation, showing much better agreement between theory and expt. B. and M. are also criticized for having assumed in their calcs. of $V (= iV)$ that the mol. vols. V of the mixts. are proportional to the mol. vols. of the components. This is wrong because the new substances produced in the reaction may have entirely different sp. gr. than the original components. The values of V should be calcd. by detg. the sp. gr. of the mixts. themselves. As possible intermediate products, PhN(OH)(NHPh)O , $\text{PhN(OH)}_2\text{NPh}$, and several others are suggested.

H. M. GORDIN.

Tri- α -thienylcarbinol. A. E. CHICHIBABIN AND N. N. GAVRILOV. *J. Russ. Phys. Chem. Soc.* 46, 1614–9 (1914).—The yield of di- α -thienyl ketone (α) by Gattermann's method (*Ber.* 18, 3013) being very low, it was prepd. by the action of $\text{C}_6\text{H}_5\text{S}$

on the α - $\text{C}_6\text{H}_5\text{SCl}$ (b) in presence of AlCl_3 . (b) was made by converting α - $\text{C}_6\text{H}_5\text{SI}$ into $\text{C}_6\text{H}_5\text{SMgI}$ (c), and treating the latter with CO_2 . The interaction of (c) with (a) gave *tri- α -thienylcarbinol*, $(\text{C}_6\text{H}_5\text{S})_3\text{COH}$ (d). The latter is easily sol. in dil. mineral acids, even in dil. AcOH , giving solns. having an intense brown-yellow color. The solns. are extremely unstable, depositing on standing dark green flakes which are insol. in acids and in org. solvents. In absence of much acid the color of the solns. disappears upon the addition of much H_2O . Owing to its instability, (d) could not be obtained in pure condition, nor could any of its salts with $(\text{CO}_2\text{H})_2$, $\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ or other acids be prepd. By mixing, however, solns. of (d) in concd. HCl with concd. solns. of the chlorides of Bi, Sb, Zn, Cd, Hg or Sn, difficultly sol. double chlorides are produced. In this way was made the salt $\text{ZnCl}_{2.2}(\text{C}_6\text{H}_5\text{S})_3\text{CCl}$, dark orange crystals having a green fuchsin-like luster. These salts are stable, and even their aq. solns. keep for a long time before they begin to deposit bluish green flakes. They are readily sol. in excess of the above metallic chlorides, indicating the existence of a series of more sol. double salts. Alkali chlorides do not ppt. solns. of (d) in HCl , nor do they make these solns. more stable. The fact that (d) is sol. even in dil. acids shows that, as a base (or pseudo-base), it occupies an intermediate position between Ph_3COH which is sol. in strong acids only, and bases of the fuchsin type. In respect to the degree of hydrolysis (d) resembles rather the latter than Ph_3COH . With regard to its constitution, $(\text{C}_6\text{H}_5\text{S})_3\text{CCl}$ is either a *p*-quinoid compd. $(\text{C}_6\text{H}_5\text{S})_3\text{C}:\text{C}:\text{CH}:\text{CH}:\text{CH}:\text{SCl}$,

or a carbonium salt. With trivalent C the above formula may be written $(\text{C}_6\text{H}_5\text{S})_3\text{CC}:\text{CH}:\text{CH}:\text{CH}:\text{SCl}$. At any rate in (d) we have a substance that is nearly

related to the dyes, without containing any typical auxochrome groups. H. M. G.

Absorption spectra and constitution of benzene derivatives. V, VI, VII and VIII. N. A. VALYASHKO AND M. V. BOLTINA. *J. Russ. Phys. Chem. Soc.* **46**, 1741-830 (1914).—**V. Dialdehyde-, dinitro- and aldehydonitrobenzenes.** In former investigations (C. A. **5**, 2101; **7**, 2226; **8**, 1422) it was proved that, as shown by the absorption spectra, the C_6H_4 ring exists in 2 isodynamic forms, an α and a φ (phenolic) form, and that different substituents favor 1 or the other of these forms, auxochrome groups favoring the φ , while chromophore groups favor the α form. So far only monosubstituted compds. have been examd. The present work concerns the disubstituted isomeric $\text{C}_6\text{H}_4(\text{CHO})_2$, $\text{C}_6\text{H}_4(\text{NO}_2)_2$ and $\text{C}_6\text{H}_4(\text{CHO})\text{NO}_2$. Several solvents were used, and in some cases HCl , EtONa or MeONa was added to the soln. The diagrammatic and profusely tabulated results may be summarized as follows: The above 3 groups of compds. have each 3 absorption bands, showing oscillation between the φ and the α forms. The general character of the spectra of disubstituted compds., when the substituents are identical, is the same as of the monosubstituted compds., the introduction of the 2nd CHO or NO_2 influencing chiefly the intensity of the bands, without displacing them towards 1 or the other end of the spectrum. In this respect the 2nd CHO and NO_2 resemble the Me and CO_2Me groups, with this difference, however, that, in accord with their auxochrome character, the latter increase the intensity of the φ bands, while the former intensify the α bands. The introduction of both chromophores and auxochromes increases the intensity of the α band for the *o*- and of the φ band for the *p*-isomers, displacing them towards the red end of the spectrum, while the *m*-isomers occupy an intermediate position in this respect, more nearly resembling, however, the *o*-compds. All these changes cannot be ascribed to quinoid rearrangements, because the displacement is entirely different for salts of *o*- and *m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ on the 1 hand, and of *o*- and *m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$ on the other, though in both cases there is a transformation into the aci form. In accord with the differences in the character of the spectra is the difference in the reactivity of the isomers,

$m\text{-C}_6\text{H}_4(\text{CHO})_2$ and $m\text{-C}_6\text{H}_4(\text{NO}_2)_2$, being less reactive than their *o*- and *p*-isomers. VI. Tautomerism of acetanilide. For this compd. (a) 2 formulas have been proposed: PhNHCOMe (b) and PhN:C(OH)Me (c). In order to decide between them, the absorption spectrum of (a) was examd., both in presence and in absence of alkali, and compared with the spectra of substances of known comp. It was found that in neutral soln. the spectrum of (a) resembled that of PhNMeCOMe , while in alk. soln. it resembled partly the spectrum of the latter, and partly that of PhN:C(OMe)Me . Hence in neutral soln. the formula of (a) is (b), while in alk. soln. part of (b) changes to (c). The change is most probably accompanied by formation of PhN:C(ONa)Me (Hantzsch, *Ann.* 296, 91). Since in (b) the C of the CO, being satd. with O, is incapable of using up much of the affinity of N, it is impossible to explain why spectroscopically the Ac behaves like a chromophore (antiauxochrome). Hence Smedley's formula MeC:O:NHPh for (a) (*C. A.* 3, 1529) is preferable to (b). The spectrum of

$\alpha\text{-C}_6\text{H}_4\text{NH.C.Me:N}$ in alc. showed 3 bands, α_1 , α_2 and φ . With increasing thickness

of the layer of soln. the φ band increases considerably, the α_1 band decreases, while the α_2 band increases very much in intensity. VII. Mono- and diacetoxybenzenes, phenylenediamines, diacetylphenylenediamines and some toluene derivatives. The changes in the spectrum of C_6H_6 caused by the introduction of substituents are due to the fact that they destroy the uniformity of satn. of its C atoms and change the distribution of affinities in the mol., different substituents exercising different influences in this respect. Since expts. prove that groups which are capable of using up more of the affinity of C than H tend to produce the φ state, it was to be expected that certain substituents in certain positions would cause radical changes in the character of the spectra. This was corroborated by a spectroscopic exam. of the above substances. Thus the acetylation of phenols reduces the intensity of the φ band and displaces it towards the red end of the spectrum. It also causes the appearance of the α_2 band, making the spectrum resemble somewhat the aldehyde type. If another AcO be introduced in the *m*-position to the 1st, the change towards the aldehyde type becomes still more pronounced, and the α_2 band becomes still more intense. When, however, the 2nd AcO is in the *p*-position to the 1st, the change in this direction is checked, and when in the *o*-position the change is even reversed, the intensity of the α_2 band becoming 3 times weaker than for mono-Ac compds. S.'s formula C:O:OH (*l. c.*) for the CO_2H group

is in better accord with the spectroscopic data and better explains the difference in behavior of the CO in acids, aldehydes and ketones than the formula C(:O)OH . Similarly, if the AcO group be assigned the formula MeC:O:O we have an explanation of

its chromophore character. In the case of the PhMe derivs. it was found that the replacement of H in the Me with satd. atoms or groups changes the character of the spectra, making them approach the aldehyde type. VIII. Benz-anti-aldoxime and benz-syn-aldoxime. According to Hartley and Dobbie (*J. Chem. Soc.* 77, 509), the spectra of these 2 compds. are identical. This is incorrect. While in general character the 2 spectra are similar, both resembling the spectrum of BzH, they differ in the intensity of the bands and in the extent of change caused by formation of salts. It is possible that the *syn* compd. exists in 2 tautomeric forms.

H. M. GORDIN.

Magnesium complexes of pyrrole, indole and carbazole in their relation to chlorophyll. V. V. CHELINTZEV AND B. V. TRONOV. *J. Russ. Phys. Chem. Soc.* 46, 1876-86(1914).—According to Willstätter (*C. A.* 1, 441), chlorophyll is a Mg org. compd., in which the Mg is linked to 4 pyrrole (a) groups, and the assimilation of CO_2 by plants is a reaction of the Grignard type. Since, however, the Mg in all the Mg org. compds.

known at present is extremely mobile, these compds. being readily decompd. by H_2O , while chlorophyll is very stable towards H_2O , W.'s formula cannot be accepted, unless it be shown that, unlike the usual Mg org. compds., the combinations of Mg with substances of the (a) type are not affected by H_2O . This C. and T. tried to prove by treating (a), indole (b) and carbazole (c) with $PrMgI$ and examg. the behavior of the resulting compds. with H_2O . It was found that the reaction at a low temp. yields complexes which begin to decomp. at ordinary temp. and completely decomp. at 70° with formation of $\underline{CH:CH.CH:CH.NMgI}$, $\underline{C_6H_4.CH:CH.NMgI}$ and $\underline{C_6H_4.C_6H_4.NMgI}$,

resp. All of these, when treated with H_2O , decomp. within a few min. with evolution of heat. Hence W.'s formula for chlorophyll requires further proof. While the last of the above 3 compds. doubtless has the above formula, the other 2 may also be $\underline{NH.CH:CH.CH:CH.CMgI}$ and $\underline{NH.C_6H_4.CH:CH.CMgI}$, resp. Expts. were also made in

order to see whether the above 3 Mg org. compds. were capable of uniting with (a), (b) and (c), resp., forming compds. of higher valences of N and I. It was found that the addition of (a), (b) and (c) to their Mg org. compds. had no thermal effect whatever. Even $EtOMgI$ which is characterized by its tendency to form complexes of higher at. valences did not cause any reaction with the 3 Mg org. compds. Evidently the double unions of the C atoms linked to the N greatly reduce the basic properties of the latter upon which depends its ability to form compds. of higher at. valences. A similar influence of double unions was observed with furane and thiophene which were also found to be incapable of forming complexes of higher valences. On the other hand, as is shown in another article (next abstr.), piperidine and tetrahydroquinoline give such complexes under the same conditions.

H. M. GORDIN.

Magnesium derivatives of piperidine, tetrahydroquinoline and hydroacridine, and the theory explaining their relative ability to form complexes. V. V. CHRENTZEV AND B. V. TRONOV. *J. Russ. Phys. Chem. Soc.* 46, 1886-98(1914).—Expts., similar to those made with pyrrole, indole and carbazole (preceding abstr.), were made with piperidine (a), tetrahydroquinoline (b) and hydroacridine (c). As shown by the thermal effects, their Mg org. compds. are readily decompd. by H_2O with evolution of considerable heat, and the compds. of (a) and (b) are capable of uniting with (a) and (b), resp., forming mono-, di- and, possibly, also triamines, in the case of the Mg org. compd. of (a), and mono- and diamines in the case of that of (b), while the Mg org. compd. of (c) gave no such complexes at all. The formulas of the mono-amines given by the Mg org. compds of (a) and (b), resp., are $C_6H_{10}:N.Mg.NH:I:C_6H_{10}$ and $C_6H_{10}:N.Mg.NH:I:C_6H_{10}$, while the corresponding diamines are, resp., $C_6H_{10}:N.Mg.NH:(C_6H_{10}):I:NH:C_6H_{10}$ and $C_6H_{10}:N.Mg.NH:(C_6H_{10}):I:NH:C_6H_{10}$. In the triamines the I is pentavalent. The difference in this respect between (a) and (b) on the 1 hand, and (c) on the other is due to the presence in (a) and (b) and the absence in (c) of double unions at the C atoms linked to the N (cf. preceding abstr.).

The quaternary salts of hexamethylenetetramine. III. Monohalogenacylated aromatic amines and their hexamethylenetetraminium (hexamethylenetetrammonium) salts. WALTER A. JACOBS and MICHAEL HEIDELBERGER. Rockefeller Inst. *J. Biol. Chem.* 21, 103-43(1915); cf. *C. A.* 9, 1610.—The halogenacylated amines were combined with hexamethylenetetramine (a) in the manner previously described (*C. A.* 9, 1612). *Chloroacetylaniline* (a) compound, m. $158-9^\circ$ (decompn.); *bromoacetylaniline* (a) compound, m. 163° (decompn.); *chloroacetylmethylaniline* (a) compound, m. $168-73^\circ$ (gas evolution); *chloroacetyldiphenylamine* (a) compound, retains a mol. of $CHCl_3$ (crystn. at 100° in vacuo, decomps. $158-61^\circ$; *chloroacetylphenylglycinanilide*, m. $118-20^\circ$ (cor.); (a) compound, m. $157-8^\circ$; *chloroacetyl- ω -anilinoacetophenone*, m. $117-8^\circ$ (cor.); (a) compound, m. $169-9.5^\circ$ (decompn.); *chloroacetyl-o-toluidine* (a) compound, m. $148-9^\circ$

(decompn.); *bromoacetyl-o-toluidinoacetophenone*, m. 107–7.5°; (a) compound, m. 175–6° (decompn.); *chloroacetyl-m-toluidine*, m. 90–1.5° (cor.); (a) compound, m. 173–4°; *chloroacetyl-p-toluidine* (a) compound, m. 176–8° (decompn.); *chloroacetyl-m-xylydine* (a) compound, m. 171–2°; *chloroacetyl-p-cumidine* (a) compound, m. 170–1° (decompn.); *chloroacetyl-α-naphthylamine* (a) compound, m. 164–5° (decompn.); *chloroacetyl-β-naphthylamine* (a) compound, m. 177–8° (decompn.); *chloroacetyl-o-chloroaniline*, m. 73.5–4° (cor.); (a) compound, m. 158–60° (decompn.); *p-bromochloroacetylaniline* (a) compound, retains CHCl_3 of crystn.; *2,4,6-tribromochloroacetylaniline*, m. 221–2° (cor.); no (a) compd. could be isolated; *m-iodochloroacetylaniline*, m. 121.5–2.5° (cor.); (a) compound, turns greenish 170°, m. 175° (decompn.); *5-iodochloroacetyl-o-toluidine*, m. 161.5–2.5° (cor.); *5-iodochloroacetyl-o-toluidine* (a) compound, m. 190–2° (decompn.); *m-nitrochloroacetylaniline* (a) compound, m. 162–3°; *p-nitrochloroacetylaniline*, m. 182–4°; *m-nitrochloroacetyl-p-toluidine* (a) compound, m. 163–4° (decompn.); *m-chloroacetylaminodimethylaniline*, m. 101.5–2.5° (cor.); (a) compound, m. 151–2° (decompn.); *p-chloroacetylaminodimethylaniline* (a) compound, contains CHCl_3 of crystn., m. 145–8°; *p-chloroacetylaminodiethylaniline*, m. 83–4° (cor.); (a) compound, m. 159–60° (decompn.); *p-nitrosodipropylaniline hydrochloride*, violently decomps. 160–5°; *p-aminodipropylaniline*, b_m 155.5–6.5°; *p-chloroacetylaminodipropylaniline*, m. 121–1.5° (cor.); (a) compound, m. 165–8° to a tar; *p-chloroacetylaminooethylbenzylaniline*, m. 106–8°; (a) compound, m. 163–4° (decompn.); *p-chloroacetylaminooazobenzene*, $\text{p-PhN}_2\text{C}_6\text{H}_4\text{NHCOCH}_2\text{Cl}$, m. 159.5° (cor.); (a) compound, dyes silk light yellow, m. 153–4°; *chloroacetylaminooazotoluene*, m. 171–2.5° (cor.); (a) compound, m. 167–9°. The following dyes were prepd. but no purified (a) compds. could be obtained: *β-Naphthaleneazochloroacetyl-β-naphthylamine*, m. 181.5–2.5° (cor., decompn.), bright orange needles, sol. in H_2SO_4 with a deep violet color; *benzeneazobenzeneazochloroacetyl-β-naphthylamine*, $\text{C}_{10}\text{H}_6(\text{NHCOCH}_2\text{Cl})\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{Ph}$, m. 190° (cor., decompn.), brick-red, micro-needles; *o-tolueneazo-o-tolueneazo-β-naphthylamine*, m. 174–7°, glistening, dark violet-brown leaflets; *o-tolueneazo-o-tolueneazochloroacetyl-β-naphthylamine*, m. 122–6° to a tar, dark brown, micro-cryst. powder; *o-tolueneazo-α-naphthylamine*, m. 97–7.5°, rosettes of orange-red hairs; *o-tolueneazo-α-naphthaleneazo-β-naphthylamine*, sinters above 140°, m. 173–8°, black-brown, micro-cryst. powder, sol. with intense blue color in H_2SO_4 . *p-Chloroacetylaminobenzeneazodimethylaniline*, m. about 205°, chocolate-brown micro-plates; (a) compound, m. 167–8.5°, dyes silk a brown-orange; *p-acetaminobenzeneazodiethylaniline*, softens 186°, fluid at 192°, orange-brown plates; *p-aminobenzeneazodiethylaniline*, m. 149–50° (cor.), dark brown crystals; *p-chloroacetylaminobenzeneazodiethylaniline*, m. 160.5–2°; (a) compound, m. 172–3°, dyes silk brown-orange; *p-acetaminobenzeneazodipropylaniline*, m. 178° (cor.), small orange needles; *p-chloroacetylaminobenzeneazodipropylaniline*, m. 112–4° (cor.), orange-brown micro-crystals; (a) compound, sinters above 100°, m. 180–1°, dyes silk brown-orange; *p-acetaminobenzeneazoethylbenzylaniline*, m. 148–50° (cor.), yellow-brown spears with violet luster; *amino deriv.*, used for the prepn. of *p-chloroacetylaminobenzeneazoethylbenzylaniline*, m. 140–1.5° (cor.), brown crystals; (a) compound, m. to a tar 140°, ochreous micro-plates; *m-bromodiethylaniline*, b_m 139.5–142°; *p-acetaminobenzeneazo-2'-bromo-4'-diethylaminobenzene*, reddens above 160°, m. 163.5–4° (cor.); its violet dil. HCl soln. dyes silk a deep yellow; *benzeneazo-2'-chloroacetyl-amino-4'-dimethylaminobenzene*, m. 109.5–10 (cor.), scarlet tablets; its dil. HCl soln. dyes silk orange; it gives a poor yield of very impure (a) compd.; *4-nitrobenzeneazo-2'-chloroacetyl-amino-4'-dimethylaminobenzene*, m. 220°, dark violet-brown, triboelec. micro-crystals, does not readily combine with (a). The following substances were obtained in expts. which were not completed: *p-diethylaminobenzenazo-β-naphthylamine*, m. 117–20°, maroon plates; *p-diethylaminobenzeneazochloroacetyl-α-naphthylamine*, m. 145° to a thick tar, chocolate-brown micro-crystals; *o-chloroacetylaminophenol* (a) compound,

m. 155°; *o*-chloroacetylaminophenyl benzoate, m. 107.5–8.5° (cor.); (a) compound, retains CHCl₃ of crystn.; *o*-chloroacetylaminophenyl *p*-nitrobenzoate, m. 163.5–4°; (a) compound, m. 171–2°; *m*-chloroacetylaminophenol, m. 134.5–6° (cor.); (a) compound, retains Me₂CO of crystn., decomps. 168°; *benzenesazo-m*-chloroacetylaminophenol, m. 200° (cor., decompn.); (a) compound, decomps. from 202–30°; its dil. NaOH soln. dyes silk pale yellow; chloroacetyl-*o*-anisidine, m. 48–8.5° (cor.); (a) compound, m. 151–3°; α -iodopropionyl-*o*-anisidine, m. 95–6.5° (cor.), would not form the (a) compd.; β -iodopropionyl chloride, b₁₅ 80.5–1.5°; β -iodopropionyl-*o*-anisidine, m. 89–91° (cor.); (a) compound, m. 172–3°; chloroacetyl-*o*-anisidinoacetophenone, m. 101.5–2.5° (cor.); (a) compound, m. 145° (decompn.); chloroacetyl-*p*-anisidine, m. 121.5–2.5° (cor.), (a) compound, m. 164–7° (decompn.); *o*-chloroacetylaminobenzyl alcohol, m. 103° (cor.); (a) compound, m. 144–5° (decompn.); *o*-chloroacetylaminobenzyl benzoate, m. 113–3.5° (cor.); (a) compound, darkens above 140°, m. 154–5°; ethyl *p*-chloroacetylaminobenzoate (a) compound, m. 155–6° (decompn.); diethylaminoethyl *p*-chloroacetylaminobenzoate (chloroacetylnovocaine) m. 63–4.5° (cor.); (a) compound, m. 128–9°; *m*-chloroacetylaminacetophenone, m. 113.5–14.5° (cor.); (a) compound, m. 165–6° (decompn.); *p*-chloroacetylaminoleucomalachite green, sinters above 80° and softens to a tar; (a) compound, m. 189–90° (decompn.); *o*-chloroacetyl-amino-*p*′, *p*′-tetraethyldiaminotriphenylmethane (a) compound, m. 177–8° (decompn.); *p*-chloroacetyl-amino-*p*′, *p*′-tetraethyldiaminotriphenylmethane (a) compound, m. 168–9°; 6-chloroacetylaminquinoline, m. 153–5° to a red tar; hydrochloride, decomps. above 250°; (a) compound, m. 203–4° (decompn.). IV. Monohalogenated simple amines, ureas, and urethans, and the hexamethylenetetraminium salts derived therefrom. *Ibid* 145–52.—The salts formed from the halogenacyl compds. and (a) are all easily sol. in H₂O and, on standing, the solns. decomp., liberating HCHO and other products, which, contrary to the behavior observed with the aromatic compds., remain in soln. α -Iodopropionamide, m. 159–60.5° (cor.), glistening needles, would not unite with (a); β -iodopropionamide, m. 141.5–2.5° (cor.); (a) compound, m. 169–70° (decompn.); chloroacetyl-methylamide, m. 45–6° (cor.); (a) compound, m. 173–4° (decompn.); chloroacetyl-dimethylamide, b₁₁ 98.5–9.5° (cor.), m. 15.5° (cor.); (a) compound, m. 160–2° to an orange liquid; chloroacetyl-ethylamide, b₁₁ 97.5–8.5°, m. 22–2.5° (cor.); (a) compound, m. 167–8° (decompn.); chloroacetyl-diethylamide, b₁₁ 125.5–30.5°; (a) compound, m. 174°, effervescing above 190°; chloroacetyl-piperidide, b₁₁ 143.5–5.5° (cor.); (a) compound, becomes pasty 168–70°, m. 184° with gas evolution; methylenebisiodoacetamide, decomps. 227–9° with evolution of I; the pure (a) compd. was not obtained; ethylenebischloroacetamide, m. 174–6° (decompn.); chloroacetylurea (a) compound, m. 176–7° when freshly prepd.; after some weeks it m. 191–2°; chloroacetyl-methylurea (a) compound, sinters 149–51°, gradually m. and decomps. 178°; chloroacetylbenzylurea, m. 153–5° (cor.); (a) compound, m. 160°; chloroacetylurethan (a) compound, m. 166–7°.

A. P. LOTHROP.

The quaternary salts of hexamethylenetetramine. V. Monohalogenacetyl derivatives of amino alcohols and the hexamethylenetetraminium (hexamethylene-tetrammonium) salts derived therefrom. WALTER A. JACOBS AND MICHAEL HEIDELBERGER. Rockefeller Inst. *J. Biol. Chem.* 21, 403–37(1915).—[Of the chloroacetyl-amines described in Paper II (*C. A.* 9, 1612) only chloroacetylbenzylamine and chloroacetyl-*o*-methylbenzylamine were prepd. from the amines and CH₂ClCOCl. The others were prepd. by the method of Einhorn (*Ann.* 343, 207, 1905; *C. A.* 2, 2682) in which HOCH₂NHCOCH₂Cl is used to introduce the —CH₂NHCOCH₂Cl group.—ABSTR.] An attempt was made to prep. a series of compds. of the esters of chloroacetylaminomethanol with hexamethylenetetramine (a). Although addition occurred, the product obtained was always the compd. of the base with the alc., not the ester. With higher alcs., it was found that both alc. and ester reacted smoothly to form stable

salts. The chloroacetyl amino alcs. were prepd. from the NH_2 alcs. and ClCH_2COCl . These were then acylated with the acid chloride in $\text{C}_6\text{H}_5\text{N}$. In some cases the aminoethyl esters were treated with ClCH_2COCl , but this is less satisfactory than the former procedure. Mol. rearrangements readily occurred with propanol derivs. in the 2nd method. For the method of prepg. the (a) compds. see C. A. 9, 1610. Hydroxymethylchloroacetamide (a) compd., m. $154-5^\circ$ (decompn.). Chloroacetylaminomethyl benzoate, m. $73-3.5^\circ$ (cor.). Anisate (*p*-methoxybenzoate), m. $106-7^\circ$ (cor.). Chloroacetylaminomethanol, $b_{0.25-0.35}$ $141-5^\circ$ (cor.). Iodoacetylaminomethanol, from the Cl compd. and NaI, not purified; (a) compound, m. $142-3^\circ$ (decompn.): trimethylamine compound, m. $138-9^\circ$ (cor.). Chloroacetylaminomethyl benzoate, m. $69-9.5^\circ$ (cor.); (a) compound, darkens 158° , m. 162° (decompn.). Chloroacetylaminomethyl *o*-toluate, m. $65-5.5^\circ$; (a) compound, m. 168° (decompn.). Chloroacetylaminomethyl *p*-toluate, m. $106-7.5^\circ$ (cor.); (a) compound, m. $161-2^\circ$. Chloroacetylaminomethyl β -naphthoate, m. $137-9^\circ$ (cor.); (a) compound, m. $174-6^\circ$ (decompn.). Chloroacetylaminomethyl *o*-nitrobenzoate, syrup; (a) compound, m. 174° . Chloroacetylaminomethyl *p*-nitrobenzoate, m. $127-8^\circ$ (cor.); (a) compound, m. $182-2.5^\circ$ (decompn.); trimethylamine compound, m. $175-6^\circ$ (cor.). Chloroacetylaminomethyl *p*-aminobenzoate, from the NO_2 compd. and SnCl_2 , m. $117-8.5^\circ$ (cor.). Chloroacetylaminomethyl *p*-[azodiethylaniline]-benzoate (chloroacetylaminomethyl ester of *p*-carboxybenzenazo-*p'*-diethylaminobenzene), from the diazotized aminobenzoate and Et_2NPh , m. 116° ; (a) compound, m. $179-81^\circ$, dyes silk a bright orange. Chloroacetylaminomethyl *o*-acetoxybenzoate m. 117° (cor.); (a) compd., m. $154-6^\circ$ (decompn.). Chloroacetylaminomethyl anisate (*p*-methoxybenzoate), m. $96.5-7^\circ$ (cor.); (a) compound, m. $153-4^\circ$ (decompn.). Chloroacetylaminomethyl cinnamate, m. $120-2^\circ$ (cor.). Chloroacetylaminomethyl ethyl ether, from $\text{NH}_2\text{CH}_2\text{CH}_2\text{OEt}$ and ClCH_2COCl , b_{15} 132° (cor.); (a) compound, m. $135-45^\circ$. Aminoethyl *o*-tolyl ether (*o*-methylphenoxyethylamine), from *o*-methylphenoxyethyl bromide and NH_3 , b_{15} 128° . Chloroacetylaminomethyl *o*-tolyl ether, from the NH_2 ether, $b_{0.7}$ $168-9^\circ$, m. $39.5-40.5^\circ$ (cor.); (a) compound, m. 162° . Chloroacetylaminomethyl ethanol, $b_{0.8}$ $130-5^\circ$. Chloroacetylaminomethyl *p*-nitrobenzoate, m. $73.5-4^\circ$ (cor.); (a) compound, m. $154-5^\circ$. Chloroacetylaminomethyl phenylaminoethanol, m. $67.5-8.5^\circ$ (cor.). Chloroacetylaminomethyl *p*-nitrobenzoate, m. $115-6^\circ$ (cor.); (a) compound, m. $167-8^\circ$. Bromoacetylaminomethyl phenylaminoethanol, m. $58-60^\circ$ (cor.). *p*-Dimethylaminophenylaminoethanol, from $p\text{-NH}_2\text{C}_6\text{H}_4\text{NMe}_2$ and $\text{CH}_2\text{Cl.CH}_2\text{OH}$, b_{16} $215-7^\circ$ (cor.), m. $32.5-5^\circ$ (cor.). Chloroacetyl-*p*-dimethylaminophenylaminoethanol, m. $85.5-7^\circ$ (cor.). *p*-Methoxyphenylaminoethanol, from $p\text{-NH}_2\text{C}_6\text{H}_4\text{OMe}$ and $\text{CH}_2\text{ClCH}_2\text{OH}$, b_{18} $188-91^\circ$, m. $43.5-4.5^\circ$ (cor.). γ -Bromopropyl-*p*-nitrobenzamide, from $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$ and $\text{CH}_2\text{BrCH}_2\text{CH}_2\text{NH}_2$, m. $107.5-8^\circ$ (cor.). γ -Aminopropyl-*p*-nitrobenzoate hydrobromide, by rearrangement from the above amide on heating in H_2O , m. $185-5.5^\circ$ (cor.). Upon treating with NaOH the free base seps. as an oil and gradually rearranges to γ -hydroxypropyl-*p*-nitrobenzamide, m. $102.5-3.5^\circ$ (cor.). γ -*p*-Nitrobenzoylaminoethyl chloroacetate, from the above amide and $(\text{ClCH}_2\text{CO})_2\text{O}$, m. $93-106^\circ$. γ -Chloroacetylaminopropyl-*p*-nitrobenzoate (the base was liberated from the HBr salt after the acid chloride had been added), m. $78-9^\circ$ (cor.); (a) compound, m. $178-9^\circ$. γ -Chloroacetylaminopropyl anisate (*p*-methoxybenzoate), as the nitrobenzoate, m. $72.5-3^\circ$ (cor.); (a) compound, m. $167-8^\circ$. Chloroacetylaminoisopropanol, $b_{0.8}$ $131-2^\circ$ (cor.), m. $33-4.5^\circ$ (cor.); (a) compound, decomps. $171-2^\circ$. Chloroacetylaminoisopropyl-*p*-nitrobenzoate, m. $133.5-4.5^\circ$ (cor.); (a) compound, darkens above 170° , m. $180-2^\circ$ (decompn.). Aminoisopropyl-*p*-nitrobenzoate hydrobromide, as the normal compd., m. $221-2^\circ$. The free base rapidly rearranges to hydroxyisopropyl-*p*-nitrobenzamide, m. $168-9^\circ$. *p*-Nitrobenzoylaminoisopropyl chloroacetate, from the amide and $\text{ClCH}_2\text{CH}_2\text{COCl}$, m. $89-94^\circ$; (a) compound, m. $175-8^\circ$ (decompn.). δ -Chloroacetylaminobutanol, $b_{1.7}$ $165-7^\circ$ (cor.), m. 30° (cor.); (a) compound, m. 125° . δ -Chloroacetylami-

butyl *p*-nitrobenzoate, m. 79° (cor.); (a) compound, darkens above 165° , m. $170-2^{\circ}$. β -Chloroacetylaminio- γ -butanol, $b_{0.3}$ 119° , m. $38-9^{\circ}$; (a) compound, m. $167-9^{\circ}$. Chloroacetylaminio- γ -butyl *p*-nitrobenzoate, m. $117-8^{\circ}$ (cor.); (a) compound, m. $189-91^{\circ}$ (decompn.). γ -Chloroacetylaminio- β -pentanol, $b_{0.3}$ $126-8^{\circ}$, m. $52-60^{\circ}$; (a) compound, m. $167-8^{\circ}$ (decompn.). Chloroacetylaminomethyl methyl ethyl carbinol (α -chloroacetylaminio- β -methyl- β -butanol), $b_{0.7}$ 134° (cor.); (a) compound, m. 170° (decompn.). γ -Chloroacetylaminio- β -methyl- β -butanol, $b_{0.4}$ 122° (cor.); (a) compound, m. $174-5^{\circ}$ (decompn.). α -Phenyl- α -hydroxy- β -chloroacetylaminioethane, m. $109-9.5^{\circ}$ (cor.); (a) compound, m. 179° (decompn.). α -*p*-Tolyl- α -hydroxyethylamine, from *p*- $\text{MeC}_6\text{H}_4\text{CH}(\text{OH})\text{CN}$ and Na-Hg , m. $68-9^{\circ}$ (cor.). α -*p*-Tolyl- α -hydroxy- β -chloroacetylaminioethane, m. $81-2^{\circ}$ (cor.). α -*p*-Methoxyphenyl- α -hydroxyethylamine, by reduction from anisaldehyde cyanohydrin. α, β -Diphenylchloroacetylaminioethanol, from the NH_3 alcohol and $(\text{ClCH}_2\text{CH}_2\text{CO})_2\text{O}$, m. $194-4.5^{\circ}$; (a) compound, m. 174° (decompn.). α, β -Isodiphenylchloroacetylaminioethanol, prep'd. as its isomer, m. $156-7^{\circ}$ (cor.); (a) compound, m. $197-9^{\circ}$ (decompn.). β -Phenyl- β -hydroxy- α -chloroacetylaminopropane, viscous oil; (a) compound, m. $175-6^{\circ}$ (decompn.). α -Phenyl- α -benzoyloxy- β -benzoylaminopropane, m. $172.5-3.5^{\circ}$ (cor.).

VI. Halogenethyl ethers and esters and their hexamethylenetetraminium salts. *Ibid* 439-53.—Attempts at combining (a) with chloroethyl ethers and esters were unsuccessful as the substances failed to react. The Br compds. were prep'd. but the reaction is slow and requires boiling in PhMe , with consequent danger of decompn., or standing for several months in CHCl_3 at room temp. The I compds. were not prep'd. as they are generally insol. Phenoxethyl bromide (a) compound, m. $151-2^{\circ}$. *o*-Cresoxethyl bromide (a) compound, m. 185° . *m*-Methylphenoxethyl bromide (*m*-cresoxethyl bromide), from *m*-cresol, $\text{CH}_2\text{BrCH}_2\text{Br}$ and NaOH , b_{14} $136-7^{\circ}$; (a) compound, m. $155-6^{\circ}$. *p*-Cresoxethyl bromide (a) compound, m. 176° . α -Naphthyl bromoethyl ether (α -naphthoxethyl bromide), from α -naphthol, $\text{CH}_2\text{BrCH}_2\text{Br}$ and NaOH , $b_{6.8}$ $154-6^{\circ}$, m. 25° (cor.), sol. in PhH , Et_2O , ligroin, sparingly in EtOH and MeOH ; (a) compound, turns yellow above 170° , m. 175° (decompn.). β -Naphthoxethyl bromide (a) compound, crysts. with CHCl_3 , not removable by boiling with Me_2CO or EtOH , m. 180° (decompn.). 2,4,6-Trichlorophenoxethyl bromide, from the phenol, $\text{CH}_2\text{BrCH}_2\text{Br}$ and NaOH , m. $47-8^{\circ}$ (cor.), sol. in Et_2O , PhH , PhMe and hot EtOH . 2,4,6-Trichlorophenoxethyl dimethylamine hydrochloride, from the above bromide and piperidine as above, m. $188-9^{\circ}$, sol. in H_2O and EtOH . *p*-Bromophenoxethyl bromide, from $\text{PhOCH}_2\text{CH}_2\text{Br}$, m. $56-7^{\circ}$ (cor.), sol. in PhH and Et_2O ; (a) compound, decomp. $185-6^{\circ}$. Tribromo-*p*-methylphenoxethyl bromide (tribromo-*p*-cresoxethyl bromide), from the phenol as above, m. $50-1^{\circ}$, sol. in PhH , Me_2CO and hot HOAc ; (a) compound, m. 181° . Tribromo-*p*-methylphenoxethyl piperidine hydrobromide, m. $223-30^{\circ}$ (decompn.). Tetrabromo-*p*-methylphenoxethyl bromide, from a prep'n. of the tribromocresol containing some tetra-Br comp'd., m. $106-7.5^{\circ}$. *o*-Acetaminophenoxethyl bromide, from the phenol as above, m. $90-0.5^{\circ}$ (cor.), sol. in PhH , CHCl_3 , less so in Et_2O ; (a) compound, m. 160° . *o*-Aminophenoxethyl bromide hydrobromide, from the NHAc comp'd. by hydrolysis with HBr , m. $193-8^{\circ}$ (decompn.). Upon addition of just enough NaOH was obtained *o*-aminophenoxethyl bromide, m. $36-7^{\circ}$ (cor.), very unstable, undergoing internal condensation. *o*-Aminophenoxethyl piperidine hydrochloride, from *o*-acetaminophenoxethyl bromide and piperidine and subsequent hydrolysis with HCl , m. $184-5.5^{\circ}$, sol. in H_2O and hot EtOH . Upon treatment with Na_2CO_3 , this yields the free base, m. $69-70^{\circ}$ (cor.). *p*-Acetaminophenoxethyl bromide (a) compound, m. $196-8^{\circ}$. *o*-Carbomethoxyphenoxethyl bromide (methyl 2-bromoethoxybenzoate), from *Me* salicylate as above, b_{10} $186-8^{\circ}$, m. $37.5-8^{\circ}$ (cor.). 2-Bromoethoxybenzamide, from salicylamide, $\text{CH}_2\text{BrCH}_2\text{Br}$ and EtONa , m. $112-4^{\circ}$. The same mixt.

also yields *salicylamide ethylene ether*, $(o\text{-H}_2\text{NOCC}_6\text{H}_4\text{OCH}_2)_2$, m. 211.5° (cor.). *Acetoxyethyl bromide* (a) compound, m. $172-3^\circ$. *Benzoyloxyethyl bromide* (a) compound, m. $164-5^\circ$. *Bromoethyl p-nitrobenzoate* (*p-nitrobenzoyloxyethyl bromide*), from *p-nitrobenzoic acid* and $\text{CH}_3(\text{OH})\text{CH}_2\text{Br}$, m. $47-50^\circ$, sol. in PhH, CHCl_3 and Et_2O ; (a) compound, m. $190-1^\circ$. *p-Nitrobenzoyloxyethyl iodide* (a) compound, m. $176-8^\circ$. No attempt was made to prep. the (a) compds. of the following esters, which were prepd. from the corresponding acyl chlorides and $\text{CH}_3(\text{OH})\text{CH}_2\text{Br}$. *Bromoethyl o-acetoxybenzoate*, from $\text{CH}_3(\text{OH})\text{CH}_2\text{Br}$ and $\text{AcOC}_6\text{H}_4\text{COCl}$, b.p. $150-60^\circ$, m. $62-2.5^\circ$ (cor.), sol. in Et_2O , CHCl_3 , PhH and hot EtOH. *Bromoethyl acetyl-p-cresolinate*, m. $62.5-3^\circ$, sol. in PhH and PhMe, difficultly in ligroin. *Bromoethyl anisate*, b.p. 140° (cor.). *Bromoethyl m-chloroacetylaminomethylbenzoate*, m. $107-8.5^\circ$. VII. ω -Halogen derivatives of aliphatic-aromatic ketones and their hexamethylenetetraminium salts. *Ibid* 455-65.—Compds. of (a) with ω -chloroacetophenones could not be prepd. owing to the slowness of the reaction and the decompn. accompanying prolonged heating of the reagents. The Br and I ketones reacted smoothly. The compds. of (a) with the Br ketones were preferred owing to their greater solubility. A number of new halogen ketones were prepd. by slightly varying the methods of Kunkell and co-workers (*Ber.* 30, 577, 1713(1897); 31, 169(1898); 33, 2641, 2644(1900)). ω -Bromoacetophenone oxime (a) compound, m. 139° (decompn.). *p-Methylphenacyl bromide* (a) compound, m. $148-9^\circ$. *p-Tolyl iodomethyl ketone* (*p-methylphenacyl iodide*), from the chloride and NaI, m. $42-3^\circ$; (a) compound, m. $157-8^\circ$. *o-Xylyl bromomethyl ketone*, from *o-xylene*, BrCH_2COBr and AlCl_3 , m. $62-2.5^\circ$ (cor.), considered to be identical with the compd. obtained from *o-xylyl Me ketone* and Br (*J. Chem. Soc.* 53, 86(1893)); (a) compound, m. $137-8^\circ$. *m-Xylyl bromomethyl ketone*, as the *o*-compd., m. $42-3^\circ$ (cor.); (a) compound, m. $145-6^\circ$. *p-Ethylphenyl bromomethyl ketone* (*p-ethylphenacyl bromide*), m. $33-4^\circ$ (cor.); (a) compound, m. $146-7^\circ$ (decompn.). *Mesityl bromomethyl ketone* (*2,4,6-trimethylphenacyl bromide*), m. $55-6^\circ$. *m-Nitrophenacyl bromide* (a) compound, m. 157° (decompn.). *p-Acetaminophenyl bromomethyl ketone* (*p-acetaminophenacyl bromide*), m. $190-3^\circ$ (decompn.); (a) compound, m. 194° (decompn.). *p-Aminophenacyl chloride* (a) compound. 3-Acetamino-4-tolyl bromomethyl ketone (*3-acetamino-4-methylphenacyl bromide*), m. $167-70^\circ$; (a) compound, decompn. $150-5^\circ$. 3-Acetamino-4-tolyl ω -iodoethyl ketone (*3-acetamino-4-methyl- ω -iodopropiophenone*), m. $142-3^\circ$ (cor.) (upon oxidation with KMnO_4 is obtained an acid, m. $279-81^\circ$ (cor.), considered to be $4,3\text{-Me}(\text{NHAc})\text{C}_6\text{H}_3\text{CO}_2\text{H}$; *Ber.* 31, 172(1898)); (a) compound, turns yellow 150° , m. $161-2^\circ$ (decompn.). *p-Methoxyphenacyl bromide* (a) compound, m. 172° (decompn.). *p-Ethoxyphenacyl bromide* (a) compound, m. $159-9.5^\circ$ (cor.). Upon treating β -acetylquinaldine with Br in HBr, the hydrobromide of the Br ketone seps. Na_2CO_3 liberates β -[ω -bromoacetyl]quinaldine, m. $102-3^\circ$ (cor.); (a) compound, m. 170° (decompn.). VIII. Miscellaneous substances containing aliphatically bound halogen and the hexamethylenetetraminium salts derived therefrom. *Ibid* 465-75.—*Hydroxyethyl iodide* (a) compound, m. 157° (decompn.). γ -Chloropropyl bromide (a) compound, turns yellow above 140° , m. $180-3^\circ$ (decompn.). γ -Hydroxypropyl iodide (a) compound. *Cetyl iodide* (a) compound, m. 157° (decompn.). *Phenylethyl iodide*, from the chloride and NaI; the fraction b.p. $104.5-30.5^\circ$ was used for the prepn. of the (a) compound, m. 159° (decompn.). *o-Iodobenzyl bromide* (a) compound, decompn. $173-5^\circ$. *Carboethoxyethyl iodide* (a) compound, m. $137-8^\circ$ (decompn.). *sec-Octyl bromoacetate*, from the alc. and CH_3BrCOBr , b.p. 137° (cor.); with (a) is obtained a gelatinous salt. *Bornyl bromoacetate* (a) compound, sinters above 170° , m. $178-81^\circ$. *Menthyl bromoacetate* (a) compound, m. $153-4^\circ$. *Phenyl bromoacetate* (a) compound, m. $149-50^\circ$ (decompn.). *Tribromo-p-cresyl bromoacetate*, softens 60° , m. $60.5-1.5^\circ$ (cor.); (a) compound, not obtained pure. *o-Nitrophenyl bromoacetate*, m. $55.5-6^\circ$ (cor.); (a) compound, m. $149-50^\circ$ (decompn.). *Benzeneazo- β -naphthyl chloroacetate*, m. $127-8^\circ$ (cor.). *Hydroxyethyl anisate* (*p-methoxy*

benzoate), from the acyl chloride and $(\text{CH}_2\text{OH})_2$, b_{0.4} 149–50°; the same mixt. also yielded ethylene anisate, m. 117–7.5°, sol. in PhH and CHCl_3 . Chloroacetoxyethyl anisate, from the HOCH_2CH_2 compd. and CH_3ClCOCl , b_{0.4} 170–5°, m. 45.5–6.5° (cor.); (a) compound, very hygroscopic, softens above 70°, completely fluid at 90°. ω -Chloroacetylaminooacetophenone, by acylation with CH_3ClCOCl , m. 124–6.5°, sol. in CHCl_3 ; (a) compound, m. 149–50°. Chloroacetylbis-[*p*-dimethylaminophenyl] methylamine (chloroacetylleucoauramine), $(\text{Me}_2\text{NC}_6\text{H}_4)_2\text{CHNHCOCH}_2\text{Cl}$, by acylation with CH_3ClCOCl , m. 164–4.5°, sol. in CHCl_3 and Me_2CO , insol. in Et_2O ; (a) compound, m. 175°, decomps. 179°. Chloroacetyltriphenylmethylamine (chloroacetyltriphenylmethylamine), by acylation with CH_3ClCOCl , m. 201–2.5° (cor.), sol. in CHCl_3 ; (a) compound, turns yellow 150°, m. 194–5° (decompn.). β -Acetyl- α -chloroacetyl- α -phenylhydrazine (a) compound, m. 192–3°. β -Chloroacetyl- α , α -phenylbenzylhydrazine, by acylation with CH_3ClCOCl , m. 112.5–3.5° (cor.), sol. except in ligroin; (a) compound m. 145–6°.

I. GREENWALD.

Purines. XVII. On a new synthesis of alkylaminopurines. On 2-oxy-8-thiopurine, 2-oxy-8-methylmercaptapurine, 2-oxy-8-methylaminopurine and 2-oxy-6,9-dimethyl-8-thiopurine. CARL O. JOHNS. Yale Univ. *J. Biol. Chem.* 21, 319–23 (1915).— MeNH_2 reacts smoothly with mercaptapurines to form methylaminopurines and MeSH . At high temps. NH_3 appears to react similarly. 2-Oxy-8-thiopurine, from 2-oxy-5,6-diaminopyrimidine and $\text{SC}(\text{NH}_2)_2$, difficultly sol., does not m. 300°; 2-oxy-8-methylmercaptapurine, from the Na salt of the thiopurine and MeI , difficultly sol., decomps. slowly above 260°, does not m. 300°. 2-Oxy-8-methylaminopurine, from the mercaptapurine and MeNH_2 , difficultly sol., does not m. 300°. 2-Oxy-6,9-dimethyl-8-thiopurine, from 2-oxy-4-methyl-5-amino-6-methylaminopyrimidine and $\text{SC}(\text{NH}_2)_2$, slightly sol. in hot H_2O and EtOH . It gives the murexide test. I. G.

The Walden rearrangement in the hexoses. P. A. LEVENE AND F. B. LAFORGE. Rockefeller Inst. *J. Biol. Chem.* 21, 345–50 (1915).—The fact that glucosamine and chondrosamine (cf. *C. A.* 9, 1768) each yield 2 different acids when deaminized and oxidized, depending upon the order in which these processes occur, indicates the occurrence of a Walden rearrangement. L. and LaF. accept the formula $\text{N:N.CRCO}_2\text{H}$ for ali-

phatic diazo acids. In this, the α -C atom is not asym. The fact that glucosaminic and chondrosaminic acids each yield only 1 HO acid, and not 2, upon treatment with HNO_3 , is thought to be due to the possible formation of 2 intermediate compds., of the

the other groups in combination with the α -C atom det. which of these compds. is formed. Ethyl monobenzalglucosaminat hydrochloride, from glucosaminic acid, EtOH , PhCHO and HCl , m. 167–8° (decompn.). From this, with NaNO_2 and HOAc , is obtained ethyl diazobenzalglucosaminat, sol. in org. solvents, insol. in H_2O . I. G.

Xylohexosaminic acid, its derivatives and their bearing on the configuration of isosaccharic and epi-isosaccharic acids. P. A. LEVENE AND F. B. LAFORGE. Rockefeller Inst. *J. Biol. Chem.* 21, 351–9 (1915).—"From xylose, by treatment with NH_3 and subsequently with HCN , a xylohexosaminic acid was obtained. On oxidation following de-amination this acid yields α , α -anhydro-idosaccharic acid. The lactone of the NH_2 acid under the same treatment leads to the α , α -anhydrosaccharic acid. Isosaccharic acid has the configuration of α , α -anhydromannosaccharic acid, while epi-isosaccharic acid is the α , α -anhydrosaccharic acid, and consequently, chitose and chitonic acid have the configuration of α , δ -anhydromannose and of α , δ -anhydro-

mannonic acid, resp.; chitaric acid has that of α,β -anhydrogluconic acid." *Xylohexosaminic acid*, from xylosimine and HCN, with subsequent hydrolysis with HCl, darkens above 190° , decomp. 235° , $[\alpha]_D^{30}$ after 20 min. 11.77° , after 40 hrs. -3.01° . *Xylohexosaminic lactone hydrochloride*, from the acid and alc. HCl, m. 195° (decompn.). *Ethyl dibenzalxylohexosaminatate hydrochloride*, from the NH_2 acid, EtOH, HCl and PhCHO m. 217° . α,α' -*Anhydro-idosaccharic acid*, from xylohexosaminic acid and HNO_3 and subsequent oxidation with HNO_3 , m. 226° (decompn.), $[\alpha]_D^{20} -93.32^\circ$; *acid potassium salt*, very sol. α,α' -*Anhydro-saccharic acid (l-epi-isosaccharic acid)*, from the above lactone hydrochloride and HNO_3 , with subsequent oxidation with HNO_3 , m. 163° , $[\alpha]_D^{20} -38.79^\circ$; *acid potassium salt*, $[\alpha]_D^{20} -38.09^\circ$. Acid K salt of *d*-anhydrosaccharic acid from glucosaminic acid, $[\alpha]_D^{20} 38.53^\circ$.

I. GREENWALD.

Angostura alkaloids. Isomerism and degradation of cusparine. J. TROGER AND W. MUELLER. Techn. Hochschule Braunschweig. *Arch. Pharm.* 252, 459-96 (1914).—The compd. isomeric with cusparine (a), $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N}$, m. 194° , formed by the action of AgOH or KOH on (a)-MeI, is not simply a demethylated (a), as is shown by a comparison with pyrocusparine (b), which is in fact a demethylated (a) and readily obtained by heating (a) in a current of dry HCl. On treatment with dil. HNO_3 in the heat, (a) and (b) suffer alike diminution of mol. wt. to the extent of $\text{C}_2\text{H}_2\text{O}$, but take on at the same time a NO_2 group. The resulting NO_2 deriv. of (a), which still contains the MeO group, is transformed on heating in a current of HCl into the NO_2 compd. yielded by (b), MeCl being evolved in the operation. On treating the NO_2 deriv. of (a) with MeI vapor, a substance is obtained identical with that formed by the action of dil. HNO_3 on isocusparine (c), the formation of which involves the intramol. change of Me from O to N, in the course of which change a CO group should be apparent. No such group, however, could be detected, and furthermore, no satisfactory explanation is offered touching the loss in mol. wt. of (a), (b) and (c) of the elements of $\text{C}_2\text{H}_2\text{O}$ as the result of treatment with dil. HNO_3 , although it is not improbable that the change may represent the partial degradation of a ring. *Isocusparine*, $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N}$, m. 194° (yielded by (a) on heating with MeI vapor or heating the methiodide, or finally on treating the MeI, EtI or $\text{C}_2\text{H}_5\text{I}$ addition products of (a) with AgOH or KOH in the presence of alc.). The *hydriodide*, $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N} \cdot \text{HI} \cdot \text{H}_2\text{O}$, S-yellow needles anhydrous at 105° , very slightly sol. in hot H_2O . (a)-HI forms yellow anhydrous needles, converted into (b) with loss of MeI on heating in a CO_2 atm. (c)-HI loses under similar treatment but at a higher temp. a small amt. of MeI and is changed into a brownish mass. *Isocusparine hydrobromide*, $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N} \cdot \text{HBr} \cdot \text{H}_2\text{O}$, bright yellow needles; the *hydrochloride*, $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N} \cdot \text{HCl}$, lemon-yellow leaflets; the *chloroaurate*, $(\text{C}_{19}\text{H}_{17}\text{O}_2\text{N})_2\text{HAuCl}_4$, orange-red prisms from alc. HCl; *acid oxalate*, $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N} \cdot \text{C}_2\text{H}_2\text{O}_4$, lemon-yellow cryst. powder stable up to 210° . On treatment with dil. HNO_3 at H_2O bath temp., (c) yields the compound, $\text{C}_{17}\text{H}_{14}\text{O}_2\text{N}_2 \cdot \text{H}_2\text{O}$, S-yellow to yellowish brown prisms from dil. AcOH, m. 239° (darkens $236-7^\circ$), sol. in AcOH, very slightly so in other solvents, only slightly basic, contains the NH group of (c). The same compd. is formed on heating the NO_2 compd. of (a), $\text{C}_{17}\text{H}_{14}\text{O}_2\text{N}_2 \cdot \text{H}_2\text{O}$ (m. 145°), in MeI vapor. The *hydriodide*, yellow anhydrous crystals, m. 239° . The *hydriodide* of the isomeric NO_2 compd., m. 145° , yellow cryst. powder contains 1 mol. H_2O . A new method for prep. (b), $\text{C}_{19}\text{H}_{17}\text{O}_2\text{N}$, consists in heating (a) at 210° in dry HCl, whereby MeCl is evolved. It is also formed on heating (a) in PhCH_2Cl vapor. (c) carbonizes on heating in HCl above 225° . (c) yields with dil. HNO_3 at H_2O bath temp. and with the evolution of gaseous products the compound, $\text{C}_{19}\text{H}_{19}\text{O}_4\text{N}_2$, bright yellow needles from AcOH, m. 283° (decompn.). The same compd. is likewise obtained by demethylating (heating with HCl) the NO_2 compd., $\text{C}_{17}\text{H}_{14}\text{O}_2\text{N}_2 \cdot \text{H}_2\text{O}$, m. 145° .

W. O. E.

Alkaloids of pareira root. M. SCHOLTZ AND O. KOCH. Univ. Greiswald. *Arch.*

Pharm. 252, 513-36(1914).—As the result of a renewed extn. of a large quantity of radix pareirae, only minute traces of bebeerine (a) (crystg. from MeOH) were obtained, the main product being amorphous β -bebeerine, thus showing the effect of seasonal influences on the character of the drug. The observation was made that crystd. (a) in time passes into the amorphous form, apparently identical with the product obtained by protracted heating of a H_2SO_4 soln. of crystd. (a). Owing to the difficulty of obtaining crystd. (a), S. and K. have confined their attention to an investigation of isobebeerine (b). On heating this substance in a tube at 160° with 5 parts Bz_2O , 2 Bz groups are introduced, one entering the phenol OH, the other uniting with the N atom, thus yielding the compd., $\text{C}_{18}\text{H}_{11}\text{Bz}_2\text{O}_2\text{N}$, as bright yellow granular crystals from alc., m. 225° ; insol. in acids, alkalis and Et_2O , sol. in concd. H_2SO_4 with a deep red color. The splitting of the N-ring is comparable to that of apomorphine and bulbocapnine, thus disposing of the erstwhile assumption to the effect that the difference in behavior of apomorphine and bulbocapnine on the one hand and of (a) and (b) on the other toward Ac_2O was due to an inability of the C atom (marked +) to yield H with the formation of a double bond, for the reason that it is already thus involved. Nascent CH_3N_2 converts (b) into *methylisobebeerine*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N}$, pale yellow amorphous ppt. from C_6H_6 + petr. ether, m. 225° (decompn.), insol. in alkalis. On treating (b) with alk. MeI, however, *methylisobebeerine methiodide*, $\text{C}_{18}\text{H}_{14}\text{O}(\text{OMe})_2\text{NMe}_2\text{I}$, results as needles, m. 294° (decomp. somewhat above the m. p.). The same product is obtained on treatment of methylisobebeerine with MeI. Me_2SO_4 converts an alk. soln. of (b) into *methylisobebeerine dimethosulfate*, $\text{C}_{18}\text{H}_{14}\text{O}(\text{OMe})_2\text{NMe}_2\text{SO}_4\text{Me}$, which with KI yields the aforesaid methiodide. *Isobebeerine ethiodide*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{NI}$, needles from hot H_2O , m. $264-5^\circ$ (decompn.). *Ethylisobebeerine ethiodide*, $\text{C}_{22}\text{H}_{18}\text{O}_2\text{NI}$, yellow cryst. powder, m. 240° . Methylisobebeerine methiodide (the methochloride much more readily) yields on boiling with caustic NaOH a mixt. of α - and β -methylisobebeerinemethine, while treatment with Na-Hg after Emde leads to the formation of the α -form solely. In view of the fact that the same methine base (containing 2 Me groups in combination with N) is formed by both the amalgam treatment and the degradation procedure after Hofmann, the conclusion is drawn that (b) belongs to the isoquinoline group. α -*Methylisobebeerinemethine*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N}$, rods from alc., m. 211° , $\alpha = 0^\circ$, sol. in cold concd. H_2SO_4 without color, while on heating the soln. becomes cherry-red. *Hydrochloride*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N} \cdot \text{HCl}$, large needles, decomp. 282° . *Sulfate*, $(\text{C}_{18}\text{H}_{12}\text{O}_2\text{N})_2 \cdot \text{H}_2\text{SO}_4$, needles becoming brown at 295° and decomp. above 305° . *Perchlorate*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N} \cdot \text{HClO}_4$, rods darkening and decomp. about 285° . *Picrate*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N} \cdot \text{C}_6\text{H}_5\text{O}_7\text{N}_3$, yellow cryst. ppt. m. $202-4^\circ$. β -*Methylisobebeerinemethine*, $\text{C}_{20}\text{H}_{16}\text{O}_2\text{N}$, needles from $\text{C}_6\text{H}_6\text{N} + \text{H}_2\text{O}$, m. 185° , more sol. in alc. than the α -form, $[\alpha]_D^{20} 171.4^\circ$ (0.14 g. in 10 cc. $\text{C}_6\text{H}_6\text{N}$), sol. in concd. H_2SO_4 with yellowish green color rapidly changing to cherry-red and then suddenly to a pure blue. *Hydrochloride*, $\text{C}_{20}\text{H}_{16}\text{O}_2\text{N} \cdot \text{HCl}$, rhombic plates. *Sulfate*, $\text{C}_{20}\text{H}_{16}\text{O}_2\text{N} \cdot \text{H}_2\text{SO}_4$, needles. *Perchlorate*, $\text{C}_{20}\text{H}_{16}\text{O}_2\text{N} \cdot \text{HClO}_4$, needles. α -*Methylisobebeerinemethine* unites readily with MeI to form the *methiodide*, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N} \cdot \text{MeI}$, rhombic plates darkening above 300° and still solid at 325° , slightly sol. in hot H_2O . On boiling with NaOH, the methiodide (more readily the methochloride, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N} \cdot \text{MeCl}$, rods m. above 310°) yields Me_2N , HI (or HCl) and the compound, $\text{C}_{18}\text{H}_{12}\text{O}_3$. On treating the methochloride with Na-Hg, the compound, $\text{C}_{18}\text{H}_{12}\text{O}_3$, results, which yields with Br a *dibromide*, thus indicating the presence of a double bond. No tetrabromide could be prepd. from the compd. $\text{C}_{18}\text{H}_{12}\text{O}_3\text{N}$. The methiodide yields no NH_4 base with Ag_2O but rather suffers oxidation. The compound, $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N}$, was obtained in the form of needles, m. 256° , insol. in but reddened by concd. H_2SO_4 . The compound, $\text{C}_{18}\text{H}_{12}\text{O}_3\text{N}$ forms rhombic leaves from alc. or AcOH, and needles from aq. $\text{C}_6\text{H}_5\text{N}$, m. 325° . The *dibromide*, $\text{C}_{18}\text{H}_{12}\text{O}_3\text{NBr}_2$, yellow granular ppt., m. $228-30^\circ$. KMnO_4 converts the compd. $\text{C}_{18}\text{H}_{12}\text{O}_3\text{N}$ into an acid and a glycol. The various reactions de-

scribed for (b) can be satisfactorily explained only on the assumption that it contains the at. grouping shown in (I), the position marked with a + indicating the asym. C

atom. Formulas (II) and (III) indicate the manner in which an opening of the mol. is effected by means of Ac_2O . While asymmetry persists in both cases, the asym. C atom itself is involved in the formation of (II), since it takes on the substituent and thus becomes racemic. (V) and (VI) represent the α - and β -forms, resp., and result from opening the methochloride as given in (IV). The methochloride (VII) yields the forms

(VIII) and (IX). Pharmacological tests carried out by Gabbe show that (b) in the

form of its cryst. sulfate and some other combinations is not an antipyretic but rather a narcotic, that it cannot be regarded as the carrier of the therapeutic action of pareira root. The following color reactions were noted in connection with (b): In the cold, concd. H_2SO_4 yields a colorless soln., while in the heat a cherry-red color is produced. On adding a drop of FeCl_3 to the concd. soln., a rose coloration gradually develops, while with a drop of concd. HNO_3 the liquid first turns brownish yellow, then rose and on warming colorless. (b) dissolves in cold concd. HNO_3 with a light brown color, the soln. becoming colorless on warming. Erdmann's reagent first produces a brownish yellow color, followed by rose and finally on warming by dark red. Millon reagent: brownish in the cold gradually changing to cherry-red. Froehde reagent: blue-violet in the cold, changing through red to brown in the heat. A drop of 1% SeO_2 develops a dark red color in a cold concd. H_2SO_4 soln. of (b), becoming brown on warming. Marquis reagent: feeble blue color in the cold, becoming reddish brown on warming. H_2SO_4 containing As_2O_3 yields a colorless soln. in the cold, changing to reddish brown in the heat. A trituration of (b) with sugar is reddened by concd. H_2SO_4 . Dissolved in $\text{K}_3\text{Fe}(\text{CN})_6$ + FeCl_3 (b) develops Berlin blue. A soln. of KIO_3 acidified with H_2SO_4 is made to yield free I by (b).
W. O. E.

The resin of *Picea vulg. L. var. Montana* Schur. HANS BINDER. Univ. Bern. Arch. Pharm. 252, 547-89(1914); cf. Tschirch and Koch, *Ibid* 240, 272.—Among the problems involved in this investigation was an attempt to demonstrate whether, on melting the resin, the cryst. constituents are changed into amorphous forms or *vice versa*. It became necessary to show in this connection also to what extent if any such

constituents are modified by the various methods of isolation. The crude resin, in which vanillin and a bitter principle were detected, is dissolved by the more common solvents, very slightly by 70% alc., acid no. (direct) 121.58, (indirect) 115.97; sapon. no. hot 119.34, cold after 24 hrs. 123.55, 48 hrs. 131.96, 72 hrs. 109.51. The product insol. in 70% alc. yielded on recrystn. from 90% alc. cryst. aggregates (A) and a cryst. meal (B). On treating (A) with Pb acetate, a sepn. was further effected into (a) pptd. by the Pb salt and (b) not pptd. thereby. (a) gave with HCl the monobasic *l*-piceapimarinic acid, $C_{20}H_{30}O_2$, light- and air-stable needles, m. $140-1^\circ$, $[\alpha]_D -21^\circ 2'$ (in alc., $c = 1.363$), I no. 86.17, without sapon. no. Silver salt, $C_{20}H_{28}O_2Ag$, very sol. in Et_2O , difficultly so in alc., insol. in H_2O . Pb salt, $(C_{20}H_{27}O_2)_2Pb$, only sol. in alc. and Et_2O in traces. (b) yielded with HCl the isomeric *d*-piceapimarinic acid, $C_{20}H_{30}O_2$, small cryst. aggregates m. $140-2^\circ$, $[\alpha]_D 5^\circ 13'$ (in alc., $c = 1.149$), otherwise very like the *l*-acid. (B) m. 138° , $[\alpha]_D -16^\circ$ (in alc., $c = 5.836$), could not be sepd. by Pb acetate into stable crystals. Steam-molten resin, which also contained vanillin, dissolved in 90% alc., acid no. (direct) 115.97, (indirect) 123.55; sapon. no. hot 133.90, cold after 24 hrs. 126.07, 48 hrs. 131.69, 72 hrs. 125.09. Exhaustion with 75% alc. yielded 4-5% mono- or triclinal crystals, m. $138-43^\circ$, $[\alpha]_D -54^\circ 28'$ (in alc., $c = 6.549$). On subjecting the crude resin to Tschirch's method of analysis (exhaustion of the Et_2O soln. in rotation with 1% solns. of $(NH_4)_2CO_3$, Na_2CO_3 and KOH), with $(NH_4)_2CO_3$, 30% of an amorphous optically active acid was extd., which on sepn. by means of Pb acetate gave 2 amorphous acids, αI and βI , the latter having the comp. $C_{21}H_{31}O_2$, m. $116-20-26^\circ$, monobasic, easily sol. in alc. and Et_2O , $[\alpha]_D -7^\circ 54'$ (in alc., $c = 2.1141$), and yielding a Pb salt sol. in Et_2O and alc., I no. 45.14, without sapon. no. A 1% Na_2CO_3 soln. dissolved 45% of the resin, the resulting crude acid yielding with Pb acetate 3 products, one pptd. as the Pb salt insol. in Et_2O (x), a second not pptd. by Pb acetate and insol. in Et_2O (y), while the third (z) is not pptd. by Pb acetate but is sol. in Et_2O . (x)- β -piceapimarinic acid, $C_{20}H_{30}O_2$, monobasic, light- and air-stable monoclinic leaflets, m. $157-62.5^\circ$, $[\alpha]_D -11^\circ 30' \pm 0.3$ (in alc., $c = 5.790$), I no. 76.42, without sapon. no. Ag salt $C_{20}H_{29}O_2Ag$; Pb salt, $(C_{20}H_{29}O_2)_2Pb$, insol. in Et_2O and only slightly sol. in alc. The mother liquor of this acid contained an amorphous optically active acid, γI . (y), monobasic γ -piceapimarinic acid, $C_{20}H_{30}O_2$, monoclinic leaflets, m. $168-9^\circ$, $[\alpha]_D -12^\circ 46'$ (in alc., $c = 3.131$), I no. 82.36, without sapon. no. Ag salt, $C_{20}H_{29}O_2Ag$; Pb salt, $(C_{20}H_{29}O_2)_2Pb$, insol. in Et_2O , moderately sol. in alc. The mother liquor contained the amorphous resin acid δI . (z), a mixt. of the resin acid ϵI , m. $90-110^\circ$, $[\alpha]_D -7^\circ 40' \pm 0.3$ (in alc., $c = 2.391$), slightly sol. in cold NaOH. 1% KOH extd. a very small quantity of an amorphous substance. The residual resene (amounting to 12%) freed from essential oil was quite sol. in alc. and Et_2O . The oil had an aromatic odor and cooling taste, b. $158-76^\circ$, $[\alpha]_D -16^\circ 42' \pm 0.3$, sol. in $CHCl_3$ and Et_2O , very slightly in alc. In applying T.'s method to the molten resin, $(NH_4)_2CO_3$ soln. gave 32% of an amorphous slightly *l*-rotatory resin acid, only a small portion of which was pptd. by Pb acetate. The non-pptd. portion was sepd. by Et_2O into 2 parts. The Et_2O -insol. part, monobasic α -piceapimarinic acid, $C_{20}H_{30}O_2$, was obtained only with great difficulty as light- and air-stable monoclinic plates, m. $164-6^\circ$, $[\alpha]_D -22^\circ 36'$ (in alc., $c = 4.656$), without sapon. no. The Ag salt, $C_{20}H_{29}O_2Ag$; Pb salt, $(C_{20}H_{29}O_2)_2Pb$. The mother liquor contained an amorphous *l*-rotatory acid, αII . The Et_2O -sol. part behaved like the substance obtained from the crude resin and was provisionally designated βII , amorphous monobasic acid, slightly colored powder, $C_{21}H_{31}O_2$, m. $80-6^\circ$, $[\alpha]_D -14^\circ 53'$ (in alc., $c = 1.9047$), I no. 56.32, without sapon. no. The resin acids extd. by Na_2CO_3 soln. were sepd. into 3 products, one pptd. by Pb acetate and insol. in Et_2O (d), another not pptd. by Pb-acetate and insol. in Et_2O (e), and a third not pptd. by Pb acetate but sol. in Et_2O (f). (d), monobasic β -piceapimarinic acid, $C_{20}H_{30}O_2$, light- and air-stable leaflets, $[\alpha]_D -24^\circ 44'$ (in alc., $c = 5.681$), I no. 76.92, without sapon. no.

Ag salt, $C_{20}H_{32}O_2Ag$; Pb salt, $(C_{20}H_{32}O_2)_2Pb$. The mother liquor contained the amorphous acid γ II. (e), γ -piceapimaric acid, $C_{20}H_{30}O_2$, light- and air-stable leaflets, m. $151-3.5^\circ$, $[\alpha]_D -4^\circ 17'$ (in alc., $c = 4.66$), very like the corresponding acid from the crude resin. (f), monobasic δ -piceapimaric acid, $C_{20}H_{30}O_3$, light- and air-stable monoclinic leaflets, m. $160-2^\circ$, $[\alpha]_D -17^\circ 8'$ (in alc., $c = 2.043$), I no. 87.15, without sapon. no. Ag salt, $C_{20}H_{32}O_2Ag$; Pb salt, $(C_{20}H_{32}O_2)_2Pb$. The amorphous acid, ϵ II, was isolated from the mother liquor. Resene was obtained in a yield of 10.6%, essential oil 0.4%. From the foregoing it appears that the resin under exam. contains chiefly *l*-piceapimaric acids, those of the crude material as isolated by T.'s method being less *l*-rotatory than the corresponding ones from the molten product. The acids obtained by the use of 70% alc. possess the same rotatory properties. The sum of $[\alpha]_D$ values obtained for the crystals isolated with 70% alc. is approx. equal to that of $[\alpha]_D$ yielded by the substances sepd. by T.'s method from the molten resin. Not only is the yield of cryst. acids greater but pure crystals are more easily and rapidly obtained from the molten than from the crude product. The piceapimaric acid formerly isolated by T. and Koch and by T. and Bruening was optically inactive. This was also true in the case of cryst. acids obtained from the crude resin on treatment with Na_2CO_3 soln. prior to sepn. with Pb acetate. On treating galipot with 70% alc., a crude acid, sensitive to light, was obtained, $[\alpha]_D 32^\circ 18'$, which could be sepd. into 2 portions by means of Pb acetate, each forming light- and air-stable crystals, the one from the pptd. Pb salt yielding $[\alpha]_D 65^\circ 18'$, the other from the sol. Pb salt, $[\alpha]_D 36^\circ 19'$. The pimaric acid from galipot gives, in distinction to the piceapimaric acids, Vesterberg's NH_3 reaction; furthermore, the latter acids contain only one double bond as indicated by the I nos.

W. O. E.

Iron compounds of phenols. VII. Compounds of eugenol and vanillin with iron. R. F. WEINLAND AND HERMANN NEFF. Univ. Tuebingen. *Arch. Pharm.* 252, 600-8 (1914); cf. Weinland and Binder, *C. A.* 8, 1785.—Sodium tetravanillinferate, $[Fe(C_8H_7O_2)_4]Na \cdot 0.5H_2O$, nearly black powder consisting of microscopic red-violet needles, was prepd. by treating 0.55 g. Fe'' acetate in 10 cc. abs. alc. with 3.8 g. vanillin in 15-20 cc. abs. alc. and 2.5 g. of 10% alc. NaOH. In a similar manner were obtained: potassium pentavanillinferate, $[Fe(C_8H_7O_2)_5]K \cdot H_2O$, black powder consisting of microscopic granular aggregates. Sodium tetraeugenolferate, $[Fe(C_{10}H_{11}O_2)_4]Na \cdot 0.5H_2O$, black powder consisting of microscopic violet right-angled leaflets. Potassium tetraeugenolferate + eugenol, $[Fe(C_{10}H_{11}O_2)_4]K \cdot C_{10}H_{11}O_2$, black powder consisting of microscopic violet right-angled plates. Acid potassium eugenolate, $C_{10}H_{11}O_2K \cdot 2C_{10}H_{11}O_2$, needles.

W. O. E.

The constitution of cantharidin. J. GADAMER. Univ. Breslau. *Arch. Pharm.* 252, 609-32 (1914).—A critical discussion of previous papers relating to this subject and a presentation of the 3 most prominent formulas: Prior to the completion of work

inaugurated by Danckwortt (cf. following abstr.) and that continued by G., no final decision with respect to the constitution can be made.

W. O. E.

The chemical nature of cantharidin. P. W. DANCKWORTT. Univ. Breslau. *Arch. Pharm.* 252, 632-6 (1914).—According to Spiegel (cf. *Ber.* 26, 142) cantharidin (a) is the anhydride of a di- CO_2H acid, while Meyer (cf. *Monatsh.* 18, 396) inclines to the belief that a free CO_2H exists in the compd. D. finds, however, that titration of (a) in neutral soln. develops a permanent red color only after an amt. of alkali corre-

sponding to 1.5 CO_2H has been added. Analysis of the K salt resulting therefrom shows that 2 CO_2H are satd. (a) behaves therefore in harmony with the observations of Spiegel like an acid anhydride, the hydrated form being unstable. The neutral K salt of the dibasic cantharidinic acid, $\text{C}_{11}\text{H}_{14}\text{O}_6$, is stable only in the absence of H_2O ; in aq soln. it becomes hydrolyzed until a point of equilibrium obtains between the neutral salt and the acid anhydride. With brucine a fairly stable salt is obtained; it could not be used, however, with success in an attempt to prep. optical isomers of (a).

W. O. E.

The action of hydrochloric acid on cantharidin. J. GADAMER. Univ. Breslau. *Arch. Pharm.* 252, 636-63 (1914).—On heating cantharidin (a) with iodized HI (d. 2.0) and under conditions excluding reduction, Piccard's diiodide, $\text{C}_{10}\text{H}_{12}\text{O}_3\text{I}_2$, is formed and in addition secondary products in form of I acids difficult of sepn., together with an indifferent substance of low I content. These acids are obtained in a yield of 20% when (a) is heated with HI (d. 1.7), while one of them resulted in a very pure state and to the amt. of 50% on allowing (a) to stand 6 months at the ordinary temp. with HI (d. 2.0). The acid in question, *dl*-hydriodocantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{I}$, is separable, by the aid of the brucine salts, into the optical congeners, $[\alpha]_D = 79-80^\circ$, while I acids obtained in other ways are not uniform and owe their formation, in part at least, to the addition of HI to cantharic acid, which always appears in greater or less amt. with the other products. At a somewhat higher temp. ($150-5^\circ$) HBr also reacts with (a) in an exactly analogous manner, yielding thereby the dibromide, $\text{C}_{10}\text{H}_{12}\text{O}_3\text{Br}_2$, together with a secondary oily, indifferent product containing apparently only 1 atom of Br. Mixts. of various acids are likewise formed, among which cantharic and hydrobromocantharic acids are the most important. The latter acid is separable into 2 optical components, $[\alpha]_D = 85.5^\circ$. When these optically active acids are heated with HBr in AcOH under the same conditions as (a), an inactive dibromide, an indifferent viscous product containing but 1 Br atom and possessing an opposite activity to that of the original acid, active hydrobromocantharic acid and cantharic acid of opposite activity result. On treating the dibromide in the same way, the substance is scarcely affected, while active cantharic acid yields an indifferent non-cryst. product together with Br acids (not identical with hydrobromocantharic acid) and active cantharic acid. Reactions involving the action of halide acids on (a) take the following course:

The reaction: $\text{HX} + (\text{a}) = \text{hydrohalidecantharic acid}$ is likewise reversible, a fact easily shown in another way. On heating active hydrobromocantharic acid for some time, a few degrees under the m. p. (220°), HBr is quant. evolved and at the same time about half the substance (inactive (a)) sublimes while the other half remains in the solid state as cantharic acid of opposite activity. The HCl addition products of (a) possess so little stability that it is impossible to isolate them. The hydrochlorocantharic acid at the high temp. of formation is apparently immediately changed into cantharic acid with corresponding loss of HCl. In view of the fact that the union of hydrogen halide with (a) consists of the mol. union of an ether

with a non-ionized hydrogenhalide, the principal reactions involved for (a), on the assumption of either Formula I or II (cf. preceding abstr.), may be represented by the following schemes, which show that active hydrohalidecantharic acid yields on the one hand inactive (a) and dihalogenide, and on the other cantharic acid of opposite activity.

Piccard's diiodide, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{I}_2$ (cf. Ber. 10, 1505), cryst. crusts from alc., gradually becoming yellow, m. $117-24^\circ$ or $133-7^\circ$, acts like an acid anhydride, is converted in part into the liquid Et ester on recrystg. from alc., converted in part into (a) with corresponding loss of HI and CO_2 . *d*-Hydriodocantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{I}$, crystals from dil. alc., becoming yellow at 160° , m. $178-80^\circ$ (evolution of HI), easily sol. in alc. *l*-Hydriodocantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{I.H}_2\text{O}$, needles turning yellow 160° , m. $179-81^\circ$, $[\alpha]_D -80^\circ$ (in abs. alc., $c = 2$). Brucine salt, m. 207° (decomps. $193-4^\circ$). *d*-Hydriodocantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{I.H}_2\text{O}$, $[\alpha]_D 79-80^\circ$ (in abs. alc. $c = 1.867$), m. as the *l*-acid. Brucine forms a neutral salt with hydrated hydriodocantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{I}.2\text{C}_{22}\text{H}_{28}\text{O}_4\text{N}_2.7\text{H}_2\text{O}$, fine needles, shrinks 100° , decomps. $100-2^\circ$ into the anhydrous form (decomps. 157°), and a normal salt of monobasic *d*-hydriodocantharic acid, thick plates containing apparently 3 mols. H_2O , decomps. 111° into the anhydrous form, m. $160-5^\circ$. Dibromide, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{Br}_2$, m. $133-4^\circ$, boils in vacuum without decompn., acts like an acid anhydride, somewhat more stable than the diiodide toward alkalies, loses HBr and CO_2 on titration. *d*-Hydrobromocantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_4\text{Br}$, needles, m. $218-20^\circ$ (evolution of HBr), monobasic and separable by means of brucine into its 2 optical components. *l*- and *d*-acids, $[\alpha]_D \pm 84.4-85.5^\circ$ (in abs. alc., $c = 2.28$), vary only slightly from the *dl*-form. Brucine salt of the *l*-acid, anhydrous, bright, hard and thick crystals, m. $222-3^\circ$ (decomps. $216-7^\circ$). Brucine salt of the *d*-acid contains apparently 4 mols. H_2O , very thin opaque leaflets, m. $183-5^\circ$ (decompn.) W. O. E.

Cantharic acid, isocantharidin and isocantharidinic acid. P. W. DANCKWORT. Arch. Pharm. 252, 663-82 (1914).—According to Gadamer (cf. preceding abstr.), the formation of cantharic acid (a) from cantharidin under the influence of hydrogen halide is due to the slight stability of the hydrohalidecantharic acid first formed, which at the high temp. involved immediately passes into (a) with corresponding loss of hydrogen halide. It was fair to assume therefore that ClSO_3H would react in a similar manner. From the fact that H_2SO_4 shows little tendency to react with cantharidin, it did not seem

probable that its Cl deriv. would show any greater tendency to yield a mol. compd. with that substance. There is formed a compd. which may be regarded as hydrochlorocantharic acid whose OH is combined in ester form with H_2SO_4 , with the result that both CO_2H groups are available for anhydride formation. In contact with H_2O , hydrolysis of the complex ester takes place leading to the formation of hydrochlorocantharic acid which immediately decomps. into (a) and HCl. The accompanying Cl-acids of indifferent and acid character are apparently the result of secondary action of HCl on (a). The latter contains a double bond and an asym. C atom and may be sepd. by brucine into its 2 physical isomers. The transition of (a) to isocantharidin under the influence of AcCl possibly takes place in accordance with the following mol. changes, on the assumption that formula (II) (*l. c.*) represents the constitution of cantharidin:

That the above formulation of isocantharidin is open to question has already been pointed out by Gadamer (*l. c.*), although it harmonizes well with the optical relations existing between the original and end product. Cantharic acid, $\text{C}_{10}\text{H}_{12}\text{O}_6$, from cantharidin by the aid of ClSO_3H according to Anderlini and Ghio, or by the action of $\text{HCl} + \text{AcOH}$ in a tube at 200° , feather-like crystals from hot H_2O , m. about 273° . On indirect titration the acid shows a decided color change, while a similar treatment of phthalidecarboxylic acid, m. $151-2^\circ$, gives no such result, the latter acid reacting like a monobasic lactone acid, being converted by an excess of alkali into a dibasic triat. acid. Such behavior on the part of (a) is additional evidence that it cannot have the constitution assigned to it by Meyer. Attempts to prepare a hydrogenated phthalidecarboxylic acid were unsuccessful. On boiling cantharidin for an extended period under a reflux condenser with $\text{H}_2\text{SO}_4 + \text{AcOH}$, the substance remains for the most part unaffected, although a very minute quantity of (a) could be detected. *d*-Cantharic acid (the difficultly sol. brucine salt has 4 mols. H_2O), needles, $[\alpha]_D^{20} 90.2^\circ$ (0.4366 g. in 25 cc. abs. alc.). *l*-Cantharic acid (the easily sol. brucine salt has 5 mols. H_2O) could not be prepd. in absolutely pure condition; $[\alpha]_D^{20} -72.6^\circ$ in abs. alc. Attempts to prep. Meyer's " α -hemellithylic acid," $\text{C}_8\text{H}_5\text{CO}_2\text{H}$, in accordance with Piccard's procedure by heating the Ba salt of (a) resulted in the formation of a minute quantity of an acid m. 134° and having a mol. wt. 156.7. (a) is converted into isocantharidin on treatment with AcCl in partially filled tubes at 135° . In this manner *l*-(a) yielded *l*-isocantharidin, $[\alpha]_D^{20} -106.4^\circ$ (0.4112 g. in 25 cc. acetone), which in contact with H_2O passes in a few hrs. into *d*-isocantharidin, and to some extent perhaps into *d*-(a) until equil. is established. Continued boiling of an aq. soln. of isocantharidin, as also heating in the dry state with a few drops HCl to about 200° , yields for the most part *d*-(a), in less degree an isomeric (a) of opposite rotation, which could not be isolated in a pure condition, however, by means of brucine. The suggestion is made that the *d*-(a) may possibly be converted into the desired structural isomer on treatment with ultraviolet light. *d*-Isocantharidinic acid, crystals from Et_2O , m. about 160° (decompn.), $[\alpha]_D^{20} 48.7^\circ$ or 46.5° (0.3900 g. in 25 cc. abs. alc.). W. O. E.

Conversion of choline into neurine. ERNST SCHMIDT. Univ. Marburg. *Arch. Pharm.* 252, 708-11 (1914).—Attempts to convert choline into neurine by the direct elimination of H_2O were unsuccessful. On heating choline chloride on the H_2O bath with pure H_2SO_4 , the main portion was unaffected, a minor portion yielding a betaine-like compd., $NMe_2.CH_2.CH_2.O.SO_2.O$. Other dehydrating agents, such as $POCl_3$,

P_2O_5 and $ZnCl_2$, failed to have the desired effect. Similarly, choline chloroplatinate heated for a long time on the H_2O bath or 1 hr. at $125-30^\circ$ with 5 parts of concd. H_2SO_4 yielded no neurine. The same substance heated to the molten state is for the most part converted into $NMe_2.HPtCl_4$. W. O. E.

Arecolidine. HERMANN EMDE. *Apoth. Ztg.* 30, 240-1 (1915).—This alkaloid occurs in minute quantities in the mother liquors resulting from the prepn. of arecoline-HBr and can be sepd. therefrom by systematic recrystn. of the HCl salts. The free base is obtained from its salts by means of caustic alkalies or alk. carbonates, even with $MgCO_3$. It is easily sol. in H_2O , alc., Et_2O and acetone. On evapn. of its solns. the alkaloid remains as a viscous oil, having a characteristic amine-like odor somewhat resembling locust (acacia). From anhydrous Et_2O the base is obtained in the form of brilliant needles, m. 105° . Sublimation raises the m. p. to 110° . On account of its hygroscopic properties the base does not lend itself well to analysis. *Arecolidine hydrochloride*, $C_8H_{11}O_2N.HCl.H_2O$, very hygroscopic, hard brilliant prisms from 99.5% alc., m. $95-8^\circ$, losing its H_2O at 100° . Heated to 250° it decomps. with evolution of gas. The *hydrobromide*, $C_8H_{11}O_2N.HBr$, thick brilliant prisms, sinters 235° , darkens 242° , decomps. $268-71^\circ$ (gas evolution). The *chloroaurate*, $C_8H_{11}O_2N.HAuCl_4$, light golden-yellow leaflets or needle-like aggregates from H_2O , m. $219-20^\circ$ (decompn.). The *chloroplatinate*, $(C_8H_{11}O_2N.HCl)_2PtCl_4$, thick, deep orange needles, sinters 214° , decomps. $222-3^\circ$. *Methiodide*, $C_8H_{11}O_2NI$, thick, yellow needles or brilliant prisms from MeOH, decomps. 264° ; *chloroaurate*, $C_8H_{11}O_2N.HAuCl_4$, golden-yellow, fern-like crystals, m. 252° (decompn.). In view of the fact that the alkaloid is unaffected by treatment similar to that which saponifies arecoline to arecaine, it is believed that the O atoms are not present as CO_2H as in the case of arecoline. The following constitutional formula is suggested: $CH:CH.C(OMe):C(OMe).CH_2.NMe$.

W. O. E

Synthesis of thiohydantoin. III. The formation of the substituted thiohydantoins. SHIGERU KOMATSU. *Mem. Coll. Sci., Kyoto Imp. Univ.* 1, 69-79 (1914); cf. C. A. 5, 2819.—The condensation of NH_2 acids with HSCN in the presence of Ac_2O has been further applied to the prepn. of several new 4-substituted hydantoins. 2-Thio-3-acetyl-4-isobutylhydantoin, formed when mol. proportions of leucine and KSCN are heated at 100° with Ac_2O for 15 min., plates from hot H_2O , m. $112-3^\circ$, converted by heating with concd. HCl into 2-thio-4-isobutylhydantoin, scales from hot H_2O , m. $169-70^\circ$. 2-Thio-4,4-dimethylhydantoin formed in like manner from $Me_2C(NH_2)CO_2H$; needles, m. $163-4^\circ$. The yield was poor (about 4%). $Me_2CHCH(NH_2)CO_2H$ gave 2-thio-3-acetyl-4-isopropylhydantoin, an oil which sepd. from hot H_2O in fine needles, m. $98-9^\circ$, giving with hot concd. HCl 2-thio-4-isopropylhydantoin; plates from hot H_2O , m. $129-30^\circ$. 2-Thio-3-acetyl-4-phenylhydantoin, needles from hot H_2O , m. $185-6^\circ$, is formed from $PhCH(NH_2)CO_2H$ and is de-acetylated by strong HCl, forming 2-thio-4-phenylhydantoin, needles from H_2O or alc., m. $211-2^\circ$ (decompn.). Aspartic acid under the same conditions did not lead to the formation of a hydantoin deriv.; cf. glutamic acid, C. A. 6, 1276-7. Most of the NH_2 acid was recovered unaltered, while NH_4Cl was isolated in amt. proportional to the quantity of KSCN used. 2-Thio-3-methylhydantoin, which cannot be prepd. by the Ac_2O method from $MeNHCH_2CO_2H$, was formed on heating $MeNHCH_2CO_2Et.HCl$ with KSCN in alc. 5 hrs.; yellow leaves from hot H_2O , m. $214-5^\circ$. 1-Phenyl-2-thio-3-methylhydantoin was formed by Aschen's

method from PhNCS and $\text{MeNHCH}_2\text{CO}_2\text{H}$; light yellow plates, m. $150-1^\circ$. In like manner *1,4-diphenyl-2-thiohydantoin* (a), needles from H_2O , m. $223-4^\circ$, was formed from PhNSC and $\text{PhCH}(\text{NH}_2)\text{CO}_2\text{H}$. A by-product, difficultly sol. in hot H_2O , sepg. in red-brown needles from alc., m. $155-6^\circ$, is to be further investigated. (a) is desulfurized by $\text{ClCH}_2\text{CO}_2\text{H}$.

NORMAN A. SHEPARD.

The ethereal oil of *elsholtzia cristata* willdenow (labiatae). II. Elsholtzic acid. YASUHIKO ASAHINA AND YOSHIATSU MURAYAMA. Univ. Tokio. *J. Pharm. Soc. Japan* 1915 (398), 361-4; cf. *C. A.* 9, 1048.—Elsholtzic acid, $\text{C}_8\text{H}_8\text{O}_3$, previously obtained by A. and M. from elsholtzia ketone in small yield, may now be prepd. in quantity from the crude Elsholtzia oil as follows: To 3.0 g. oil in 40 cc. abs. Et_2O with 1.0 g. finely cut Na 6.0 g. AmNO_2 is added slowly with cooling and the mixt. allowed to stand at room temp. 24 hrs. H_2O is then added, the soln. satd. with CO_2 , extd. with Et_2O , the H_2O soln. acidified with HCl and again extd. with Et_2O . After removal of the Et_2O , elsholtzic acid remains as an oily mass, which soon solidifies; yield 0.5-0.7 g. It is purified by heating in H_2O with small amt. of NH_4Cl and Zn dust, filtering when decolorized, acidifying with HCl and extg. with Et_2O . Recrystd. from H_2O , it m. 134° . Sodium salt, $\text{C}_8\text{H}_7\text{O}_3\text{Na}\cdot\text{H}_2\text{O}$, plates. Potassium salt, cryst. powder from H_2O . The calcium and barium salts both sep. without H_2O of crystn. Lead salt, $(\text{C}_8\text{H}_7\text{O}_3)_2\text{Pb}\cdot\text{H}_2\text{O}$, clusters of leaves; silver salt, white powder; copper salt, $(\text{C}_8\text{H}_7\text{O}_3)_2\text{Cu}\cdot 6.5\text{H}_2\text{O}$, green leaves; ferric salt, $\text{Fe}(\text{C}_8\text{H}_7\text{O}_3)_2\cdot\text{OH}\cdot 4\text{H}_2\text{O}$, yellow needles. Methyl ester, from the Ag salt and MeI , leaves, m. $3-8^\circ$. Ethyl ester, leaves, m. $47-8^\circ$. Acid chloride, by the action of SOCl_2 on the free acid, m. $21-2^\circ$, b. 175° . Amide, leaves, m. $85-6^\circ$. Anilide, m. 91° .

NORMAN A. SHEPARD.

Crystallographic study of some nitro derivatives of benzene. H. STEINMETZ. Munich. *Z. Kryst. Min.* 54, 467-97(1915).—Complete crystallographic descriptions are given of $\text{C}_6\text{H}_4(\text{NO}_2)_2$, the *o*-, *m*- and *p*-forms of chloro-, bromo- and iodonitrobenzenes, 3,5- $\text{Cl}_2\text{C}_6\text{H}_3\text{NO}_2$, 3,5- $\text{ClBrC}_6\text{H}_2\text{NO}_2$, $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{I}$, *o*- and *m*-nitrophenol, 2,6-, 3,4-, 2,3- and 3,5-dinitrophenol, also, supplementary to previous papers (S. and Gossner, *C. A.* 8, 1766), a new or entation of $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and measurements on *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$, 2,4-, 3,5- and 2,6-(O_2N) $_2\text{C}_6\text{H}_2\text{CO}_2\text{H}$.

E. T. WHERRY.

Tormentol, the extract of *Potentilla tormentilla* Neck. A. GORIS AND C. VISCHNIAC. *Compt. rend.* 160, 77-80(1915).—Tormentol is obtained from the roots of *Potentilla tormentilla* Neck. by extn. with hot Me_2CO of the fraction pptd. from the macerated roots by basic Pb acetate. The ext. is pptd. with H_2O and the ppt. recrystd. from dil. EtOH . It m. $227-8^\circ$; $[\alpha]_D$ in 90% EtOH 10.78° . Cryoscopic and analytical data give the formula $\text{C}_{22}\text{H}_{30}\text{O}_{10}$. It seems to polymerize on heating to 100° and appears to be an ester since it yields an alc. (m. 310°) and an acid (m. 280°) on sapon. With acid anhydrides it gives esters, indicating the presence of an OH group. E. M. F.

Action of sunlight on cinnamic acid. A. W. K. DE JONG. Buitenzorg, Java. *Verslag. Akad. Wetenschappen Amsterdam* 23, 1255-9(1915); *Proc. Acad. Wetenschappen* 17, 1274-7(1915).—Further expts. on the formation of α - and β -truxillic acid from normal and allocinnamic acids (cf. *C. A.* 6, 2746). Allocinnamic acid, cinnamic acid, and mixts. with α - and β -truxillic acids were exposed to sunlight and the nature of the effect detd. for various conditions. The results indicated that, contrary to previous conclusions, β -truxillic acid is not formed by combination of a mol. each of the allo- and the normal cinnamic acids. Normal cinnamic acid can give both α - and β -truxillic acid, while the formation of the β -acid from allocinnamic acid is a secondary process. The effect of the sunlight is affected by the fineness of the substances exposed, and by the interposition of glass. Samples of com. cinnamic acid were found to contain up to 3% of β -truxillic acid, and allocinnamic acid was obtained in quantity by exposing a soln. of Na cinnamate to sunlight.

Reactions of sodium malonic ester. C. LORING JACKSON AND F. C. WHITMORE. *J. Am. Chem. Soc.* 37, 1522-37(1915).—The present paper gives exptl. proof of the theory that the 1st step in the reaction of sodiomalonic ester (a) and org. halogen compds. consists in addition of the halogen compd. to the enol form of (a), the more negative part of the halogen compd. (usually the halogen atom, but in some cases the org. radical) adding to the C atom carrying the ONa (*C. A.* 6, 615). The following facts furnish evidence of the formation of such an addition product: when the pale yellow bromotriiododinitrobenzene (b) is treated with colorless (a) in the cold the mixt. becomes blood-red and is decolorized by acids (owing to the formation of $\text{BrI}_2\text{C}_6\text{H}(\text{NO}_2)_2$ and $[\text{CH}(\text{CO}_2\text{Et})_2]_2$ or $\text{CHI}(\text{CO}_2\text{Et})_2$). Similar color changes have been observed in 83 analogous reactions. Moreover, 10 cc. of abs. alc. dissolves 10 g. of the red product but only 1.5 g. of (a) and 0.043 g. of (b). When (a) is treated with an excess of *sald.* alc. (b), filtered, evapd. *in vacuo*, the Na in the residue detd. and there is deducted from the wt. of this residue the amt. of (b) sol. in a vol. of alc. equal to that of the soln. taken, the % of Na found agrees within 0.2% with that calcd. for the addition product (c), $\text{BrI}_2(\text{O}_2\text{N})_2\text{C}_6\text{H}(\text{ONa})(\text{OEt})\text{CO}_2\text{Et}$, irrespective of the concn. of (a) in the soln. In similar expts. in $\text{C}_6\text{H}_5\text{-EtOH}$ with an excess of (a), the % of halogen in the residue differed from the calcd. by 1.25% at most. A large amt. of the product of the reaction between (a) and (b) was then fractionated into 29 fractions and it was found that the excess of (a) and (b) accumulated in the 1st and last fractions, while the 4 middle fractions all contained the amt. of halogen calcd. for (c). A method is also described whereby triiodoaniline can be prepd. pure with tolerable certainty, and the prepn. of (b) has also been improved. The cold solns. of (c) in C_6H_6 and alc. are quite stable if protected from acids and H_2O , but heating decomps. them and all evapns. must be carried out at room temp. Attempts to prep. insol. compds. by replacing the Na by other metals (Ag, Ca, Fe'' , Hg'') were unsuccessful. The residue left by evapg. solns. of (c) *in vacuo* over KOH is a red oil or tar changing to an amorphous dark red solid; in only 1 case were obtained a few red plates which may have been (c) in cryst. form.

CHAS. A. ROULLIER.

Azulene, a blue hydrocarbon. II. ALFRED E. SHERNDAL. *J. Am. Chem. Soc.* 37, 1537-44(1915); cf. *C. A.* 9, 596.—Azulene (a) combines in alc. with 1 mol. picric acid, the *picrate* sepg. out almost at once in jet-black needles, m. about 120° , regenerates (a) with dil. alkalis or H_2O , sol. in alc., acetone and Et_2O with green, in C_6H_6 and AcOEt with blue color; CCl_4 and benzine dissolve out the (a), leaving the picric acid behind. The color intensity of (a) is such that 0.64 g. in 1 l. benzine matches 0.24 g. CuSO_4 in 1 l. NH_4 . Using the method described in the 1st paper, 0.03% (a) was iso-

lated from a dark bluish green fraction of oil of cubebs. By the action of $\text{Ac}_2\text{O} \cdot \text{H}_2\text{SO}_4$ blue oils were obtained from oils of amyris, guaiac wood and gurgun, and from the latter (a) was isolated as the picrate. The sesquiterpene fraction of the oil of eucalyptus also gave a greenish blue oil while oil of cedar wood and caryophyllene of clove oil did not. With H and colloidal Pd in 50% alc. (a) is quant. reduced in 12 hrs. to a tricyclic *dihydrosesquiterpene*, $\text{C}_{15}\text{H}_{28}$, $d_{20} 0.8935$, $n_D^{20} 1.490$, $[\alpha] = 0^\circ$, insol. in 63% H_2SO_4 , gives an intense color with Ac_2O and a trace of H_2SO_4 and with Br in AcOH . It is probably identical with dihydro- α -gurjunene, the approx. consts. of which, derived from Semmler's data (C. A. 8, 2376), are: $d_{20} 0.900$, $n_D 1.492$. Sherndal concludes that (a) is closely related to the sesquiterpenes in structure, is tricyclic and therefore has 4 ethylene bonds, has an aromatic nucleus, has no aromatic conjugate double bond and has a peculiar arrangement of the double bonds which accounts for the intense color, such a color intensity being exhibited by no other known hydrocarbon.

C. A. R.

Constitution of the so-called dithiourimidoacetylacetone. WILLIAM J. HALE. *J. Am. Chem. Soc.* 37, 1544-52 (1915); cf. C. A. 9, 1065.—With concd. H_2SO_4 , CH_3Ac , and $\text{CS}(\text{NH}_2)_2$ in alc. yield acetylacetoneithiourea (2-thiopyrimidine) (a) whereas with a few drops of concd. HCl in abs. alc. there is obtained after 3 days, together with varying amts. of (a)-HCl, the *hydrochloride*, m. 219° , of Evans' dithiourimidoacetylacetone (b) (*J. prakt. Chem.* 48, 489 (1893)). As it is very difficult to sep. the 2 HCl salts the $\text{CS}(\text{NH}_2)_2$ and CH_3Ac were brought together, without acids, in alc. or H_2O , and in both cases small yellow crystals of the free (b) appeared in several days. The slight solubility of $\text{CS}(\text{NH}_2)_2$ in alc. renders H_2O a better medium for the prepn. of (b) which is obtained in 91% yield from 3 g. $\text{CS}(\text{NH}_2)_2$ and 2.5 g. CH_3Ac in 5 cc. H_2O heated 10-2 hrs. in a sealed tube at 98° . (b) can also be obtained in much lighter yellow form by slow condensation (several weeks) of the components in H_2O in the dark. It seps. from alc. or H_2O in monoclinic prisms, m. 192° , readily blackens HgO or basic Pb acetate in H_2O ; CHCl_3 exts. none of the intermediate (a) from the reaction product. (b) is also obtained when the components are boiled without solvents 5-6 hrs. or, with less decompn., when they are heated in a sealed tube 24 hrs. at 98° ; CHCl_3 exts. some (a) from the residue left by evap. the mother liquors. Again, (b) is obtained from 1 mol. each of concd. aq. $\text{CS}(\text{NH}_2)_2$ and (a) at room temp. (b) is therefore clearly (6-thioureido-4,6-dimethyl-2-thio-1,2,5,6-tetrahydropyrimidine (2-thiopyrimidinethiourea) (I).

When 1 g. is boiled 5 hrs. with 1.5 g. $\text{ClCH}_2\text{CO}_2\text{H}$ in 15 cc. H_2O , it is completely desulfurized to 2-ketopyrimidine-urea. In 3 or 4 cases where $\text{CS}(\text{NH}_2)_2$ and CH_3Ac had been allowed to stand in alc. in stoppered tubes over the summer months, more or less exposed to sunlight, and the dark yellow cryst. product was extd. with boiling alc., there remained undissolved 2,4-dithioureinopentane (II), insol. in practically all solvents, sol. in acids and in CH_3Ac , does not blacken HgO but with boiling $\text{ClCH}_2\text{CO}_2\text{H}$ yields de Haan's diureinopentane (C. A. 2, 2559). $\text{CS}(\text{NH}_2)_2$ with CH_3Ac therefore yields 3 S products analogous to the 3 O compds. obtained with urea.

CHAS. A. ROUVILLER.

Inosite and pinite and some of their derivatives. EDWARD G. GRIFFIN AND J. M. NELSON. *J. Am. Chem. Soc.* 37, 1552-71 (1915).—Attempts to synthesize inositol (a) or compds. closely related by (1) aldolization between the C : O and CH_2OH groups of glucose, (2) removal of HBr from bromotetraacetylglucose, (3) C_6Cl_6 and AgOAc

and (4) hydrolysis of benzenetrichlorohydrin failed. (a) was then prepd. from "steep water," a by-product in the manuf. of corn products (368 g. pure (a), rhombic prisms with 2 H₂O from H₂O or dil. AcOH, m. 225°, from 42 l. steep water). Gently heated 10 min. with 18 g. AcBr, 3 g. (a) gives 7 g. of the hexaacetate. When 25 g. (dried at 110°) was heated 6 hrs. in sealed tubes with 100 g. AcBr at 120°, however, the following products were obtained: C₆H₅Br(OAc)₃ (Müller, C. A. 7, 1357), indistinct crystals from alc., m. 240°; α-C₆H₄Br₂(OAc)₄, scaly crystals from alc., long, flat prisms from C₆H₆, m. 225° (M. gives 235°); β-C₆H₄Br₂(OAc)₄ (b), rhombic prisms from alc., m. 130° (M., 140°); *dibromotriacetylcyclohexanetetrol*, slender prisms from alc., m. 124°, yields (b) on acetylation; *dibromodiacetylcyclohexanetetrol*, needles from alc., m. 240° (decompn.), gives (b) on acetylation; *tribromotriacetylcyclohexanetriol*, microscopic plates from C₆H₆, m. 180°; C₆H₄Br₂(OH)₄, massive prisms from H₂O, m. 216° (decompn.) (M., 210°), small prisms from AcOEt, tufted crystals from alc., gives (b) on acetylation. Repetition of M.'s work gave compds. of the same m. p. as those reported above. These halogen esters are not affected by AlCl₃ and C₆H₆ or Na and EtBr in Et₂O, only slightly by Ag₂CO₃ in boiling MeOH; PhMgBr in Et₂O gives dark resins; liquid NH₃ (which, however, was later found to contain large amts. of impurities, such as H₂O, Fe, C₆H₅N, etc.) with (b) gave only C₆H₄Br₂(OH)₄. With AcCl 6 hrs. at 140° (a) gave the following derivs., none of which seems to be identical with M.'s compds.: *Chloropentaacetylcyclohexanepentol*, indistinct crystals from alc., m. 250°; α-*dichlorotetraacetylcyclohexanetetrol*, scales from alc., m. 186°; β-*isomer* (c), rhombic prisms from alc., m. 118°; *dichlorotriacetylcyclohexanetetrol*, b. 216–7°, brittle gum, gives (c) on acetylation and with alc. HCl yields *dichlorocyclohexanetetrol*, prisms from alc., m. 221°, gives (c) on acetylation; *dichlorodiacetylcyclohexanetetrol* (?), needles, m. 107°. The following hexa-, penta- and tetraacyl derivs. of (a) were prepd. by dissolving (a) and the acid chloride at 120° in slightly more quinoline than the amt. necessary to react with the chloride, dissolving the resulting syrup in CHCl₃, washing 2–3 times with dil. H₂SO₄, concg. and adding warm alc. to incipient crystn.: *Hexabenzozoate* (cf. Maquenne, *Compt. rend.* 104, 297(1887)), microscopic crystals from alc., m. 258°; *pentabenzozoate*, prisms from C₆H₆, m. 269°; *tetrabenzozoate*, amorphous powder from CHCl₃-EtOH, m. 231°. *Hexaanisate*, prisms from CHCl₃-EtOH, m. 225°; *pentaanisate*, microscopic needles, m. 251°. *Hexacinnamale*, needles from CHCl₃-EtOH, m. 199°; α-*pentacinnamale*, microscopic prisms from CHCl₃ and alc., m. 271°; β-*isomer*, amorphous powder, m. 125°. *Hexa-m-nitrabenzozoate*, needles from AcOEt, m. 217°; *penta-m-nitrobenzozoate*, powder from AmOH, m. 226°. ClCO₂Et under the same conditions gives a hygroscopic syrup pptd. from Ac₂O and 2 drops of H₂SO₄ by H₂O as an oil, gradually solidifying to an amorphous mass sol. in alc. but with simultaneous formation of (a) (possibly due to alcoholysis); on acetylation the syrup gives 2 *hexaacetylcyclohexanehexols* different from the hexaacetate (d) obtained by direct acetylation of (a); α-*form* flat prisms from alc., m. 212°; β-*isomer*, microscopic prisms from alc., m. 200°. In 1 case the α- changed into the β-form but the transformation could never be repeated, nor could (d) be converted into the above hexaacetates by warming with ClCH₂CO₂Et and quinoline or with Ac₂O satd. with HCl. Repetition of Fick's work (*Chem. Zentr.* 1887, 452) gave (d) as the only cryst. deriv.; it seps. from PhMe in monoclinic prisms, m. 216°, sublimes 200°; b. 234°; liquid NH₃ gives only (a). (a) is unchanged by heating with CH₃N₃, 15% KOH and MeI in alc., Ag₂O and MeI in MeOH, MeOH and HCl in a sealed tube, Me₂SO₄ in quinoline or C₆H₅N. With Me₂SO₄ in 25% NaOH boiled 24 hrs., however, and subsequent acetylation of the product, (a) yielded *mono-methylcyclohexanehexol*, microscopic prisms from alc., m. 204°; *pentaacetylmethylcyclohexanehexol*, needles from Et₂O, m. 141°, takes up 1.5 H₂O on standing in the air and then m. 96°; *tetraacetyldimethylcyclohexanehexol*, prisms from alc., m. 223°, sublimes above 300°; *triacetyldimethylcyclohexanehexol*, syrup, b. 212–3°. With

Et_2SO_4 are obtained: *pentaacetylcyclohexanehexol*, needles, from Et_2O , m. 128° ; *tetraacetyldiethylcyclohexanehexol*, prisms from alc., m. 212° , sublimes unchanged above 300° , yields with alc. $\text{Ba}(\text{OH})_2$ *diethylcyclohexanehexol*, prisms from alc., m. 212° . Pinite (monomethylcyclohexanehexol) (e), obtained from the roots of *Pinus lambertina*, prisms from MeOH, m. 186° , sublimes above 200° , gives the Scherer test, $[\alpha]_D^{25} 65.3^\circ$ (0.6950 g. in 100 cc. H_2O); gently warmed with AcBr for 0.5 hr. it gives the *pentaacetate*, prisms from 80% MeOH, m. 98° , $[\alpha]_D^{20} -9.67^\circ$, while 15 min. boiling with BzCl yields the *pentabenzoate*, amorphous powder from 80% MeOH, m. 97° , $[\alpha]_D^{20} 32.3^\circ$. *Pentaanisate*, obtained with the chloride in quinoline at 120° , needles from alc., m. 101° , $[\alpha]_D^{20} = 0^\circ$. *Pentacinnamate*, amorphous powder from alc., m. 105° , $[\alpha]_D^{20} 41.2^\circ$. *Nitrate*, from (e) in a mixt. of 1 vol. fuming HNO_3 and 2 vols. H_2SO_4 , syrup with a bitter taste, easily decomps. on heating, explodes when struck. With AcBr at room temp. 72 hrs. in sealed tubes, (e) gives α - and β - $\text{C}_6\text{H}_4\text{Br}_2(\text{OAc})_4$.

CHAS. A. ROUILLER.

Temperature coefficients and the effects of acids, bases and salts in reaction velocities of triphenylmethane dyes. H. C. BIDDLE and C. W. PORTER. *J. Am. Chem. Soc.* 37, 1571-89 (1915); cf. *C. A.* 8, 665.—The influence of changes in temp. and in the concns. of acid and base and the effect of neutral salts upon the velocity of the development of color and of fading of Ph_3CH dyes was studied by following the change of color of crystal violet (a) in a Stammer colorimeter. It was found that the temp. coeff. of the change carbinol $\rightarrow$ quinoid in the presence of HCl is independent of the concn. of the acid (0.0026-0.0234 *N*) and, between 25 - 40° , of the temp., the increase in velocity of the change being 66% for every 5° . The same is true for the reverse change in the presence of KOH (0.0033-0.0083 *N*) but the temp. coeff. is smaller (43% for 5°). The rate of fading in the presence of alkalies is proportional to the HO ion concn. (in the case of acid dyes, like phenolph., the increase in the velocity of fading is slightly greater than the increase in the HO ion concn.). Expts. on mono-, di- and triaminotriphenylmethane dyes showed that the rate at which these basic dyes acquire color in the presence of acids varies with the concn. of the acid in such a way that it passes through a minimum at a definite acid concn. (different for each dye); for (a) the concn. of acid corresponding to this minimum is approx. 0.0234 *N* HCl; for malachite green, 0.007 *N*. The rate of developing color of (a) in the presence of HCl (0.004 *N*) and NaCl becomes slower as the concn. of NaCl increases, and equimol. amts. of NaCl and KCl have the same effect. The reverse change in the presence of KOH is similarly retarded, the rate of fading being almost a linear function of the sq. root of the equiv. concn. of the salt. All univalent neutral salts (NaCl, KCl, NaNO_3 , NaBr, NaI, KNO_3) in equiv. concns. are equally effective in modifying the catalytic influence of the acid or base; they behave like acids in their effect upon basic dyes and like bases in their influence on acid dyes, the fading of phenolph. being accelerated by neutral salts. In the conversion of a basic dye from the carbinol to the colored form in the presence of an acid, the salt effect depends on the concn. of the acid, being indifferent at that particular concn. of acid at which the rate of development of color is minimum, accelerating at higher and retarding at lower concns. of acid. The equil. is also displaced by neutral salts; in acid solns. addition of salts produces variations in color in the same direction as increase in the concn. of acid. Alc. and acetone have an effect on basic dyes just the opposite of that of salts, the change in rate, however, being relatively greater as the concn. of alc. or acetone increases. Sugar reduces the rate of fading, probably owing to a diminution of HO ions by formation of glucosates between the base and the sugar.

Conversion of galactose pentaacetate to an isomeric form. C. S. HUDSON and H. O. PARKER. *J. Am. Chem. Soc.* 37, 1589-91 (1915).—From 50 g. galactose penta-

acetate, m. 142° , $[\alpha]_D^{25}$ in CHCl_3 , prepd. by the method of Erwig and Koenigs (*Ber.* 22, 2207(1889)), heated on the H_2O bath with 150 cc. Ac_2O and 10 g. ZnCl_2 until the rotation becomes const. (about 15 min.), is obtained about 70% of an isomeric *pentaacetate*, easily cryst. from alc., m. 95.5° , $[\alpha]_D^{20}$ in 100 cc. soln., 106.7° (3.2500 g. in CHCl_3), 94.8° (1.6816 g. in C_6H_6), 113.6° (3.9480 g. in MeOH), 114.0° (3.3732 g. in AcOH).

CHAS. A. ROUILLER.

The existence of a third crystalline pentaacetate of galactose. C. S. HUDSON. *J. Am. Chem. Soc.* 37, 1591-3(1915); cf. preceding abstr.—When 175 g. galactose is acetylated with Ac_2O and NaOAc and poured into cold H_2O , recrystn. from 95% alc. of the ppt. gives the pentaacetate (a), m. 142° ; if the filtrate is neutralized with NaHCO_3 , extd. with CHCl_3 , the ext. mixed with the mother liquors from (a) and the CHCl_3 allowed to evap. slowly at room temp., more (a) seps. in a few days (total yield, 163 g.); from these final mother liquors there is obtained, after crystn. from alc., 20 g. of a 3rd *pentaacetate*, m. 98° , $[\alpha]_D^{20} -41.6^{\circ}$ in CHCl_3 . Only 2 pentaacetates can be accounted for on the basis of the usual stereoisomeric structures; the existence of a 3rd form may be due to the O-ring linkage being on some other than the γ -C atom (cf. Fischer, *C. A.* 8, 3036).

CHAS. A. ROUILLER.

Catalytic reduction of γ -pyrones. W. BORSCHKE. Univ. Göttingen. *Ber.* 48, 682-6(1915).—Contrary to what happens with yangonin (*C. A.* 9, 312) the pyrone ring in γ -pyrone and some of its simplest derivs. can be reduced with comparative ease. Thus, 15 g. γ -pyrone in 20 cc. H_2O , 4 cc. of 1% gum arabic and 2 cc. of 2% PdCl_2 satd. with H under atm. pressure give *tetrahydro- γ -pyrone*, b. $163-6^{\circ}$, miscible with H_2O within wide limits. *Semicarbazone*, very sol. *Phenylcarbamimic hydrazone*, $\text{O}(\text{CH}_2-\text{CH}_2)_2\text{C}:\text{NHCONHPh}$, needles, m. 169° . β,β' -*Dibenzal derivative*, from the ketone in alc. with BzH and NaOH , light yellow rhombic leaves from $\text{EtOH}-\text{CHCl}_3$, m. 158° . β,β' -*Dianisal derivative*, yellow needles from $\text{EtOH}-\text{CHCl}_3$, m. $179-80^{\circ}$ to a turbid, $222-3^{\circ}$ to a clear liquid. β,β' -*Dicinnamal derivative*, yellow leaflets from $\text{CHCl}_3-\text{EtOH}$, m. $213-4^{\circ}$, sol. in H_2SO_4 with deep blue color. α,α' -*Dimethyltetrahydro- γ -pyrone*, b_m 170° ; *semicarbazone*, prisms from about 10 parts H_2O , m. 192° ; *phenylcarbamimic hydrazone*, needles from alc., m. $211-2^{\circ}$. The pyrone does not condense with aromatic aldehydes. *Diethyl tetrahydro- γ -pyrone- α,α' -dicarboxylate* (*diethyl tetrahydrochelidonate*), b₁ $200-15^{\circ}$, m. $80-2^{\circ}$; *phenylcarbamimic hydrazone*, needles from dil. alc., m. 164° .

CHAS. A. ROUILLER.

4-Hydroxypiperidine and 4-aminopiperidine. BRUNO EMMERT and WILHELM DORN. Univ. Würzburg. *Ber.* 48, 687-92(1915).—To 30 g. 4-hydroxypiperidine in 300 cc. alc. in a 5 l. flask provided with a Dimroth reflux condenser is added 100 g. Na at such a rate that the vapors are just condensed, 1 l. alc. added in 100 cc. portions to the mixt. on the H_2O bath, then 1 l. H_2O and excess of concd. HCl and the soln. is evapd. to dryness. Repeated extn. with alc., diln. with H_2O , evapn. to dryness and 2 more treatments with alc. and evapns. yield 30 g. of the crude HCl salt of 4-hydroxypiperidine; the free base, obtained by dissolving the salt in 40% KOH and extg. 30-40 times with Et_2O , b₇₄ $211-2^{\circ}$ (cor.), m. 86° , quickly absorbs CO_2 and H_2O from the air, gives in 10% soln. with phosphomolybdic acid a yellow ppt., with phosphotungstic acid in the presence of HCl a white gelatinous ppt. sol. on heating and sepg. in tables on cooling; $\text{BiCl}_3\text{-KI}$ ppts. a cinnabar-red powder; Nessler reagent gives a white ppt. *Hydrochloride*, slender prisms from alc., quickly deliquesces in the air. *Chloroaurate*, long prisms from H_2O . *Benzoate*, from the HCl salt and BzCl heated 5 hrs. at 120° , b₁₁ $169-70^{\circ}$, sol. in about 100 parts H_2O at room temp.; *hydrochloride*, m. about 230° when heated rapidly; *chloroaurate*, needles from H_2O ; *chloroplatinate*, prisms from H_2O ; *1-nitroso derivative*, $\text{BzOCH}(\text{CH}_2\text{CH}_2)_2\text{NNO}$, from the HCl salt in H_2O and concd.

KNO_3 treated 5 min. with steam, m. $77-9^\circ$ when heated rapidly from 70° . 12 g. 4-aminopyridine, obtained from 4- $\text{C}_5\text{H}_4\text{NCl}$ heated 4-5 hrs. at $220-30^\circ$ with 5-6 parts $\text{ZnCl}_2 \cdot \text{NH}_3$, gives with Na in alc. 8.5 g. of 4-aminopiperidine hydrochloride, m. $332-5^\circ$ (decompn.) when heated rapidly; chloroplatinate, prisms from H_2O .

CHAS. A. ROUILLER.

Naphthalenemonosulfonic acids. ORRO N. WITT. Berlin. *Ber.* 48, 743-72 (1915).—Having need of a large amt. of pure β - $\text{C}_{10}\text{H}_7\text{SO}_3\text{H}$, W. made a thorough study of it and the α -isomer and found that a number of errors concerning these substances have crept into the literature and have been accepted as true for a long time. A method was devised for prepg. the β -acid whereby the 1st stage in the usual process (*i. e.*, formation of the α -acid), was avoided and the free acid was obtained pure directly, without passing through the Pb or Ca salt, by taking advantage of the fact that acids "salt out" a new trihydrate (*a*), which is capable of existence only below 70° . Into 250 g. C_{10}H_8 kept at 160° is poured 400 g. of 93.7% H_2SO_4 at such a rate that the temp. remains const. at 160° (about 15 min. are required); the heating is continued 5 min. at most and the clear, light reddish brown liquid poured into 2 l. cold H_2O . About 2 g. of $(\text{C}_{10}\text{H}_7)_2\text{SO}_2$ (chiefly β, β) is formed in the reaction but this almost completely seps. out in cryst. form in the course of 24 hrs. The small amt. remaining in soln. may be extd. with C_6H_6 if desired. The amt. of α -acid formed is such that if the filtered soln. is vigorously boiled in a porcelain dish until the temp. of the boiling liquid is 115° (the liquid then weighs 925 g.) and the dish is covered and cooled, the α -acid salts out (*a*). If it is not desired to sep. the sulfones (which is the case when the acids are eventually to be converted into salts), the evapn. may be avoided by pouring the sulfonation mixt. into only 300 cc. H_2O . Under the above conditions the crude product contains 15% of the α - and 85% of the β -acid and of the latter 85% fully 80 seps. as the trihydrate on cooling and even more if the temp. is brought down to $8-10^\circ$. The cryst. magma is mashed to a thick paste, centrifuged in a Ni basket or filtered through a Pukall filter and pressed out in an acid-proof press through coarse unbleached muslin. 600 g. of the press cake in 300 cc. H_2O at 70° are then treated with 100 cc. of HCl (d. 1.19); on slow cooling and allowing to stand in the ice chest, (*a*) again seps. practically quant. and is treated as above and finally kept over concd. aq. NaOH *in vacuo*. So obtained, it forms snow-white, gleaming crystals, m. 83° , free from every trace of the α -acid, perfectly stable in the air, even in the hottest summer weather; if kept over H_2SO_4 or CaCl_2 12-24 hrs. *in vacuo* or a longer time under atm. pressure, it goes over into the monohydrate, m. 124° , which in the air again goes over into (*a*). Again, if (*a*) is covered with a little Et_2O , it slowly melts, without dissolving, to a strongly refractive liquid, the Et_2O apparently splitting off 2 mols. H_2O which then dissolves the resulting monohydrate; on standing in the air, the Et_2O very slowly evaps. and (*a*) is reformed. Towards many other solvents (PhOH liquefied with H_2O , 80% HCO_2H , almost all alkyl aliphatic esters), however, (*a*) is very stable, sepg. unchanged even from solns. which have been prepd. hot. The 3rd mol. of H_2O can be removed in a current of dry air at the temp. of boiling PhMe , the resulting anhydrous acid being an extremely hygroscopic but *not* deliquescent substance; in the air it swells and powders up like CaO and finally forms a cryst. powder of (*a*); the absorption of H_2O is so rapid that the m. p. cannot be detd. in the usual way; the (*a*) must be dehydrated in a tiny bulb attached to a capillary which is then at once sealed; the anhydrous acid then m. $90.5-1.0^\circ$ and is very sol. in C_6H_6 , PhMe and other solvents in which the hydrates are insol., but these solns. always deposit mixts. of the hydrates. If the anhydrous acid is heated in dry air at the temp. of boiling PhNH_3 , it again loses 1 mol. of H_2O , the product being a glassy mass which becomes porcelain-like when covered with H_2O and finally dissolves to a milky liquid containing innumerable microscopic spheres and sepg. from alc. in

transparent spheres. By representing the monohydrate and (a) by the formulas $C_{10}H_8S[:O^{IV}(OH)H]_2$ and $C_{10}H_7S[:O^{IV}(OH)H]_2O^{IV}(OH)H$, a picture is obtained of the different ways in which the H_2O mols. may be combined in them. From the pure β -acid obtained as above a number of its salts were prepd. from the corresponding metallic hydroxides or carbonates in H_2O ; almost all are normal and apparently often isomorphous; at least, almost all sep. in quadrangular tablets. *Ammonium salts*, anhydrous, becomes milky 150° , dissolves in 7 parts H_2O at 25° and 1 part boiling H_2O , seps. from H_2O in monoclinic prismatic tables, $\infty P\infty, \infty P, \neq P, + P$ being usually absent, however. *Na salt*, glass-like leaves, sol. in 17 parts H_2O at 25° ; only when it is contaminated with the α -isomer does it sep. in the form of the shimmering leaflets in which it is generally known. *K salt*, non-hygroscopic crystals with 0.5 H_2O . *Pb salt*, snow-white, non-hygroscopic, 6-sided leaflets with 1 H_2O , which it loses at 180° . *Zinc salt*, seps. with 6 H_2O , all of which it gradually loses from $100-80^\circ$, sol. in 221 parts H_2O at 25° . *Cobalt salt*, flesh-red 6-sided leaves with 6 H_2O which it quickly loses at a high temp., becoming red-violet. *Nickel salt*, light green crystals with 6 H_2O , yellow when anhydrous. *Cadmium salt*, soft pearly leaves with 6 H_2O which it loses at 80° . *Copper salt*, light turquoise-blue crystals with 6 H_2O , depositing a small amt. of a basic salt on long boiling of its solns., sol. in MeOH and EtOH, loses 4 H_2O at $75-80^\circ$, becoming white, and the other 2 H_2O at 125° , becoming lemon-yellow. *Silver salt*, crystals gleaming like polished Ag, somewhat sensitive to light, melts at a high temp.

CHAS. A. ROULLER.

Constitution of succinylosuccinic ester and its halogen derivatives. A. HANTZSCH. *Ber.* 48, 772-85 (1915).—It has now been established by chem. and optical methods that the ester (a) is a "fixed" dienol, $CH_2.C(OH) : C(CO_2R) CH_2.C(OH) : CCO_2R$,

which under no conditions yields a ketone or keto-enol equil. in detectable amts. This extraordinary stability of the enol is related with its cyclic structure as a *cis*-enol and can be more readily perceived from the formula (I) with secondary valences, only

cyclic *cis*-enols forming directly a 6-membered ring by conjunction and thus being able to stabilize themselves, while open enols, like $MeC(OH) : CHCO_2R$, can escape the *cis*-configuration and ring formation by going over into *trans*-enols. Finely divided solid (a) or its alc. soln. at 0° or room temp. instantly and sharply absorb 4 atoms Br, forming a colorless soln.; in other media the reaction is slower but that the (a) is present only in the enol form is shown by the fact that its solns. in various solvents (EtO, EtOH, MeOH), show practically the same absorption and while in AcOH it is somewhat more transparent, addition of a little concd. H_2SO_4 produces no further change, and moreover this slight change is not in the direction of keto forms of succinylosuccinic esters, as shown by comparison with the spectrum of the ketonic *C*-dimethylsuccinylosuccinic ester, insol. in alkalies (v. Baeyer, *Ber.* 25, 2123 (1892)). The difference in behavior of (a) towards Br in various solvents is probably due to the formation of addition products of different stability and reactivity. The *tetrabromide*, which is relatively stable only in its colorless alc. soln., is decompd. into its components by much H_2O ; the same is true of the fresh AcOH soln. poured upon ice and of the alc. and AcOH solns. evapd. *in vacuo* even below 0° , but the alc. soln. shaken with AgCl in the dark gives an alc. soln. of the *tetrachloride*, in which the halogen, as in the case of the bromide, can be quant. titrated with KI. Both tetrahalides give with $FeCl_3$ a red-brown color. No evidence

could be obtained of the existence of intermediate labile α -dihalides; when (a) is shaken with 2 atoms alc. Br at 0° , 0.5 of it is recovered unchanged; similarly an alc. solution of the tetrabromide treated with 2 mols. concd. aq. KI at once deposits 0.5 of the substance as (a). On the other hand, if (a) is pptd. in finely divided form by adding H_2O to its boiling satd. alc. soln. and cooling quickly, filtered, dried, covered with a little Et_2O and treated at -15° with Cl till a permanently yellow soln. is obtained, the apparently unchanged (a) is really almost pure β -dichloride, probably (II), sepg. from org. solvents on cautious crystn. in needles, decomp. 106° , gives no color with $FeCl_3$, no I with KI and no $AgCl$ with Ag_2O , forms no tetrachloride with Cl in any solvent; only with Zn dust and $AcOH$ does it instantly regenerate (a). On warming with alc., long heating or standing several weeks in a KOH desiccator, it quant. forms dihydroxy-*p*-phthalic ester (b). The β -dibromide could not be obtained; only dibromoquinone-dicarboxylic ester (c) could be isolated from the reaction mixt. While the α -tetrahalides show selective absorption similar to that of (a), the β -dichloride shows only general and much weaker absorption. That the change of an enol into a true enol dibromide changes the absorption but little is also shown by ethoxycrotonic and acetoacetic esters and their dibromides in alc. and hexane, resp. A 3rd series of halide derivs. is obtained (the tetrahalides probably being intermediate products) when (a) is pptd. from a warm satd. soln. with 0.25 vol. H_2O and treated with Br vapor at -10° until the soln. has become dark yellow. The apparently unchanged (a) is filtered, washed with Et_2O at -10° and very quickly dried; it is the labile *diethyl dihydroxytetraphthalate* α -dibromide (III), loses Br at $40-50^\circ$ with formation of (b) and at the same time

quickly rearranges into the stable β -dibromide (IV) which undergoes the above decompn. only at 88° ; it is obtained directly instead of (III) when the operations are carried out at a higher temp. and more slowly; when dry it is stable for a short time but always smells faintly of Br and cannot be recrystd. Its spectrum lacks entirely the very deep band of (b). It is probably identical with product obtained by Herrmann from solid (a) and Br vapor (*Ann.* 211, 327(1882)). The dibromides quant. liberate I from KI and in alc. at once absorb Br; the expected hexabromide could not be isolated, the product being (c). The by-product obtained by Zeckendorf in the oxidation of (a) with Br, which he thought was a hydrate of (b), really contains 23% Br and is probably a mixt. of (b) with its dibromide.

Action of hydrogen ions on phagocytosis in *Carchesium lachmani*. N. K. KOLTZOV. Moscow. *Intern. Z. physik. Chem. Biol.* 1, 82-107(1914).—Increase of the H-ion concn. (also of the OH-ion concn., though to a lesser extent) inhibits the phagocytosis of *Carchesium lachmani*. The reaction is quite delicate between certain limits and might be available as a method of measuring H-ion concn. E. M. FRANKEL.

Changes in the colloidal state of starch. M. SAMEC. Vienna. *Intern. Z. physik. Chem. Biol.* 1, 173-88(1914).—Review of the author's previous papers (cf. C. A. 6, 1913; 7, 3767; 8, 837; 9, 468).
E. M. FRANKEL.

Physico-chemical reactions of enzymes in the stomach after administration per os. A contribution to the nature of zymogens. E. PRIBRAM AND A. PERUTZ. Vienna. *Intern. Z. physik. Chem. Biol.* 1, 269-74(1914).—Zymogens may be explained on the basis of simple adsorption phenomena. The living rabbit stomach readily adsorbs pepsin and rennin, also trypsin, and in alk. medium. The enzymes can be obtained from the mucosa by the usual methods of obtaining zymogens. To activate the enzyme the reaction of the medium must be opposite to that used in extg. the zymogen. Addition of 10% sugar soln. prevents adsorption of the enzyme by the gastric mucosa without affecting the ferment.
E. M. FRANKEL.

Influence of certain capillary-active substances on enzyme activity. G. H. CHAPMAN. Prag. *Intern. Z. physik. Chem. Biol.* 1, 293-337(1914).—Invertin, pepsin, trypsin and catalase are inhibited by various alcohols, esters and ketones. The effects of surface tension do not follow any isocapillary law nor the law of Traube. The effect of univalent alcs., etc., unless influenced by specific toxic action decreases with increase in lipid nature of the substance. There is evidence that enzymes are hydrophile in nature. The action of alcs., etc., is apparently due to a coagulation of the enzyme. Protective colloids retard the inhibition. Lipase acts differently from other enzymes studied, being inhibited by CHCl_3 and accelerated by alcs. below certain concns. It may be a hydrophilic colloid or a lipid.
E. M. FRANKEL.

Antagonism and balanced solutions. R. H. TRUE. Washington. *Science* 41, 653-6(1915).—A review of the conceptions of antagonism and synergism. T. regards balanced and nutrient solns. as cases of antagonism, the salts tending to remove the ill effects of pure H_2O and of certain components.
E. M. FRANKEL.

Balanced solutions and nutritive solutions. J. LOEB. New York. *Science* 41, 757-8(1915).—L. objects to True's view (cf. preceding abst.) that balanced and nutrient solns. are of the same nature, since the lack of a given nutrient deprives the organism of a necessary building stone and this may produce malnutrition or a deficiency disease.
E. M. FRANKEL.

The biochemistry of lipoids. Studies on the adrenals. III. N. C. BORBERG. Copenhagen. *Skand. Arch. Physiol.* 32, 287-354(1915).—The adrenal cortex contains cholesterol esters of the fatty acids, free fatty acids, and phosphatides, but no triglycerides of fatty acids. The fatty acids consist in large part of the higher unsatd. acids. The zona glomerulosa contains phosphatides, the zona fasciculata the cholesterol esters, and the zona reticularis the fatty acids and pigment. In pathological alterations, the most typical change is in the cholesterol-containing zona fasciculata. In pregnancy and chronic kidney disease, there is an increased amt. of cholesterol esters; in most intoxications and infections, a decreased cholesterol content and increased fatty acid content with simultaneous infiltration of the organ with blood phosphatides. The pathological changes in the adrenals are not qual., but rather quant. and are changes of localization. The cholesterol lipoids from adrenals pass to the liver, then to other organs after fatty infiltration of the liver.
H. B. LEWIS.

The influence of poisons on enzymic processes. III. Arsenic compounds and phosphorus. C. G. SANTESSON. Stockholm. *Skand. Arch. Physiol.* 32, 405-28(1915).—Relatively strong solutions of H_2AsO_3 (N/154) and H_2AsO_4 (N/180), and of Na_2AsO_3 and neosalvarsan depressed the activity of the catalytic enzyme of frog muscle. The action of neosalvarsan is coincident with its decompn. Na_2AsO_4 , Na cacodylate and atoxyl had little or no influence. In very weak soln. (e. g., H_2AsO_3 0.042%,

H_2AsO_4 , 0.016%, etc.), the substances studied showed an optimum concn. at which there was a tendency to stimulation of the normal catalytic activity. A soln. made by allowing P to stand in water overnight lowered catalytic activity. H. B. LEWIS.

Enzyme inhibition. II. L. LICHTWITZ. Göttingen. *Z. physiol. Chem.* **94**, 73-8(1915); cf. *C. A.* **6**, 2437.—The earlier studies on the result of enzyme inhibition in a medium containing invert sugar are confirmed. The negative results of Euler and Cramer (*C. A.* **8**, 1129, 1593) were due to the use of too large a number of cells (18×10^{10} per 100 cc. soln. instead of 8 million). G. M. MEYER.

Hardness of water in relation to perfection of the teeth. ROSE. *Giorn. farm. chim.* **62**, 406(1913).—R. has shown that, while H_2O with a high content of salts (especially Ca salts) is rather injurious to health, the soundness of the teeth is in direct proportion to the degree of hardness of the H_2O used as a beverage in the locality in question. The finest dentition was found, on the whole, in localities where the H_2O contained Mg salts (which harden the enamel) in addition to Ca salts. H. S. PAINE.

The organic phosphorus compound of wheat bran and the hydrolysis of phytin. R. J. ANDERSON. New York Agr. Expt. Sta., *Tech. Bull.* **40**, 3-31(1915); see *C. A.* **9**, 1622. R. C. ROARK.

Combination of protein with halogen acids. J. H. LONG AND MARY HULL. *J. Am. Chem. Soc.* **37**, 1593-606(1915); cf. *C. A.* **9**, 1624.—When mixts. of proteins and varying amts. of 0.2 N HCl are slowly evapd. and heated to practically const. wt. at 105° , the increase in wt. (av., 0.0655 g. for 0.677 g. dry fibrin) shows that HCl is added alone, without H_2O (i. e., without hydrolysis), the av. amt. of added HCl, as calcd. from the amt. of Cl in the residue, being 0.0646 g. Expt. having shown that high temp. causes some increase in the amt. of HCl added (750 mg. dry casein adding an av. of 70.9 mg. when evapd. on live steam and 67.8 mg. when evapd. slowly on a H_2O bath), in subsequent expts. the solns. were allowed to stand several weeks over H_2SO_4 , then over powdered NaOH and finally dried to const. wt. not above 75° . In this way were obtained very const. results, agreeing closely (in the case of HCl and HBr) with those obtained on the H_2O bath and final drying at 105° . Using the equiv. of 750 mg. anhydrous protein in each case, it was found that casein adds 71.5, 269.6 and 420 mg. HCl, HBr and HI, resp.; fibrin, 62.6, 278, 415 mg.; egg albumen, 71.3, 329, 413 mg. In the case of HI, the constancy in combining ratios found with HCl and HBr is lacking, the increase in wt. not being always equal to the amt. of I taken up, calcd. as HI; the increase in wt. is sometimes even less than the HI added, showing that substitution as well as addition has taken place. In the course of evapn. and drying the residues become dark but CS_2 and CHCl_3 do not ext. free I. When the solns. are evapd. on the H_2O bath, the protein may combine with as much as 75% of its wt. of HI, the resulting compd. having a brownish ocher-yellow color and no longer giving the protein reactions. Detn. by the usual titration method of the acid held by the proteins gives much lower results, probably owing to the lack of delicacy of the indicator in the presence of unaltered protein but especially on account of the dissociation of the protein-acid complex; if, instead of titrating the mixt. directly, it is filtered and the insol. portion is washed with successive portions of H_2O , titration of the wash waters shows that 7-8 washings remove about 0.2 of the HCl or HBr held by the egg albumen, 0.1 from the fibrin and 0.25 from the casein and about 0.66 of the HI from the egg albumen and more than 0.5 from the fibrin. When a fine uniform coagulum of egg albumen is vigorously stirred or shaken with HCl, titration of the mixt. shows that the max. of HCl addition is not reached even after long standing; if, however, the coagulum is ground in a mortar with the acid, this max. is quickly reached. C. A. R.

Origin of the humin formed by the acid hydrolysis of proteins. ROSS A. GORTNER AND MORRIS J. BLISH. *J. Am. Chem. Soc.* **37**, 1630-6(1915).—Van Slyke's conclusion

that the N of tryptophan (*a*) is not transformed into humin N when boiled with HCl (C. A. 5, 1938, 3295), holds only when the (*a*) is boiled alone; when it is added to a protein a considerable portion of its N passes over into the humin fraction (approx. 0.0070 g. when added to 1 g. zein), the remainder being distributed between the bases and the filtrate from the bases. There is no increase in the ammonia N. The formation of humin reaches a max. with 0.125 g. (*a*) per g. zein, showing that it involves not only (*a*) but also some product of hydrolysis. When (*a*) is boiled with dextrose, practically 90% of its N remains in the humin fraction, while the hydrolysis of zein in the presence of the sugar gives rise to a slight increase in humin N, possibly owing to the presence of (*a*) in zein in such a small amt. that it is difficult to detect by the color tests; certainly, the loss in ammonia N in zein and gliadin hydrolyzed in the presence of dextrose, as compared with the amt. found when the proteins are hydrolyzed alone, is not much greater than the exptl. error. Histidine plays no part in the humin formation, as shown by the hydrolysis of zein in its presence. The reaction involved in the humin formation is probably a condensation of an aldehyde with the NH group of (*a*). The product of the hydrolysis of zein + dextrose is a jet-black suspension of solid non-nitrogenous humin, so that absorption of NH_3 by non-nitrogenous humins plays no important part in the formation of humin N. CHAS. A. ROULLIER.

Oxidizing enzymes. VII. Action of carbon dioxide upon tyrosinase. R. CHODAT AND K. SCHWEIZER. *Arch. sci. phys. nat.* 39, 327-31 (1915).—Tyrosinase extd. from toad-stools frequently contained both laccase and peroxidase. By using the ext. in acid medium, the action of tyrosinase is inhibited. It was found that H_2CO_3 had a remarkable effect when used. Pure washed CO_2 when passed through a mixt. of 9 cc. glyccoll (0.75 g./250), 3 cc. *p*-cresol (1 g./250), and 2 cc. tyrosinase (0.05 g./20) shows no color reaction even at the end of 30 min. When CO_2 was passed into separate solns. of glyccoll, of *p*-cresol and of tyrosinase (all of the strengths indicated above), in the last case only was a color change observed. It was found that CO_2 had no effect upon a tyrosinase soln., through which had previously been passed H for an hour but that instead a deep blue color developed with *p*-cresol naturally and immediately. Some preparatory action, possibly a combination of enzyme with fermentable substance, was shown in the following way: the mixture of tyrosinase, *p*-cresol and glyccoll was treated by bubbling H through it; for 1 hr.; no rose color resulted, evidently because the H prevented any oxidation but if this mixt. were then exposed to the air, the coloration was produced in 5 min. **VIII. The production of benzaldehyde by tyrosinase.** *Ibid* 331-4.—Phenylglyccoll when treated with tyrosinase for 12 hrs. is found to decompose to produce NH_3 , CO_2 , and benzaldehyde. Peptone added to the mixt. seemed to hinder the action. To show that aldehyde is produced in plants, a leaf of the poppy, a plant containing considerable tyrosinase, was wrapped in dark paper and allowed to remain undisturbed for 20 hrs. This darkened leaf, as well as one exposed to the light, was ground with water, distd. and Schryver's aldehyde test carried out with the filtrates. The distillate from the darkened leaf did not give any color reaction, while the other gave a faint test for an aldehyde. The most plausible conclusion is that the aldehyde formed prevented the photolysis of CO_2 and of water. The addition of chlorophyll ext. to glyccoll in absence of CO_2 does not hasten the decompn. into aldehyde but if tyrosinase be added and light shut out as much as possible, the action is very greatly accelerated. Testing with Schryver's reaction gave a red fuchsine color, showing the presence of much aldehyde. In the same way a strong positive test for benzaldehyde was obtained when phenylglyccoll was treated with tyrosinase in a mixt. protected from the air by a layer of toluene. These tests probably explain the production of benzaldehyde by hydrolysis of protein mols. and show that chlorophyll is of importance because of its reducing action. **IX. Peroxidase as a rea-**

gent for the photolysis by chlorophyll. *Ibid* 334-8.—An ext. of chlorophyll was made in the winter from green leaves using alc. and benzene according to the method of Hoppe-Seyler; the operation was carried out in the dark. The soln. was allowed to evap. spontaneously on lumps of marble to spread the powder over a large surface. About 0.5 g. of this paste was then placed in test-tubes which were filled $\frac{2}{3}$ full of water charged with CO_2 and allowed to stand for 3 days, one in the light, the other in the dark. The first when examd. showed the presence of HCHO . To show that H_2O_2 is produced in molecular quantities with aldehyde, peroxidase was added to a 2% pyrogallol soln. and this with the carbonated chlorophyll soln. gave a strong reaction. In the leaf, H_2O_2 is constantly decomposed by catalase and atomic O produced. The distribution of catalase in light and dark parts of several plants was studied and it was found that the darker parts contained less of the catalase, for exts. of them liberated less O_2 from a given vol. of H_2O_2 than did the ext. from the lighter portion.

The estimation of acetone in urine. N. O. ENGFELDT. Stockholm. *Skand. Arch. Physiol.* 32, 253-86(1915).—A critical study of the sources of error in the detn. of acetone in urine by the Messinger-Huppert method. The use of $\text{H}_3\text{C}_2\text{O}_4$, AcOH , or H_3PO_4 is recommended for the acidification of the urine before distn.

H. B. LEWIS.

Nature of the Abderhalden reaction. J. BRONFENBRENNER. West Penn Hosp., Pittsburgh. *Biochem. Bull.* 4, 87-9(1915); cf. *C. A.* 9, 920.—"The Abderhalden reaction is specific, but depends not as Abderhalden believes, on the presence of specific enzymes, but on the presence in the blood of pregnant women of the specific antibody that combines with placenta antigen, and thus sets free the only proteolytic enzyme which is always present in the serum of every animal. The Abderhalden test should be positive wherever the complement-deviation test is positive." In many instances a positive reaction has been obtained with the sera of syphilitics, using pure lipid antigen, in which the only source of protein cleavage products was the serum of the patient, proving that the serum itself and not the substrate is digested in the Abderhalden test.

C. BACTERIOLOGY.

ERNEST D. CLARK.

Adaptation of the organisms of lactic fermentation to the medium. C. RICHT. Paris. *Ann. inst. Pasteur* 29, 22-54(1915).—The degree of acidity in lactic fermentation furnishes a remarkably accurate and easily obtained measure of the adaptation of organisms to the media on which they are grown. The following salts in various concns. were added to milk and the effects on lactic fermentation noted: K_2SeO_4 , K_2PO_4 , KNO_3 , $CuSO_4$, $NaCl$, KBr , K_2AsO_4 , $Te(NO_3)_2$. Adaptation was found to be the rule and there was also a diminution of the activity of the ferment when returned to act upon normal milk. In each case, except with $NaCl$, the activity was less than that of normal ferment. Coincident with this diminution of activity, the enzyme showed a greater activity (as compared with the normal) when it was allowed to grow on the solns. to which it had become adapted.

GEO. T. CALDWELL.

Germicidal value of iodine. T. MAHON AND J. S. WHITE. *Chem. and Druggist* 1915, 144.—By the Rideal-Walker method it was shown that a soln. of 0.5-0.25% I in C_2H_5OH or H_2O was about 4 times as powerful a germicide as C_2H_5OH . J. GAUB.

Enzymes in the mycelia of *Penicillium glaucum* grown on a nitrogen-free medium. DONATO FRANCESCHELLI. Univ. Neapel. *Centr. Bakt. Parasitenk., II Abt.* 43, 305-22(1915).—The ext. of the mycelia of *Penicillium glaucum* grown on a fat- and protein-free medium, contains a proteolytic enzyme which can act in an alk., neutral or slightly acid reaction. It digests protein as completely as does trypsin. This enzyme dialyzes very slowly. The ext. does not affect raw starch but digests cooked starch and inverts cane sugar. Dialysis inactivates the diastase but a small amt. of acid activates it. The ext. does not produce alc. from grape sugar. It does not contain lipase and rennin.

JULIAN H. LEWIS.

The germicidal effect of lactic acid in milk. P. G. HEINEMANN. Univ. Chicago. J. *Infect. Dis.* 16, 479-86(1915).—Some acid-tolerant cells of *B. coli* may survive the presence of 0.6% lactic acid in milk. *B. dysenteriae*, *B. typhosus*, *B. paratyphosus B*, and *Spirillum cholerae* were destroyed by the presence of 0.45% lactic acid. It is probable that other strains of these bacteria exist which are able to resist a greater amt. of lactic acid. Acid-tolerant strains of *B. coli*, *B. dysenteriae*, *B. typhosus*, and *B. paratyphosus B* may multiply in the presence of quantities of lactic acid that are destructive to the majority of cells. The smaller the initial amt. of lactic acid, the more likely is the growth of acid-tolerant strains. Consequently, the slower milk sours, the greater is the danger of pathogenic bacteria surviving. The growth of test bacteria is influenced to a marked degree by the amt. of acid present. Up to a fairly definite proportion of acid there is an increase in numbers, followed by a decrease, which becomes more pronounced as the proportion of acid increases. The amt. of acid may increase after the number of bacteria has commenced to decrease, owing to the liberation of enzymes. Acids other than lactic acid are frequently present in buttermilk. Buttermilk therefore should be looked upon with suspicion, especially if heavily polluted, unless prepared from pasteurized milk. Still, the chances of buttermilk becoming a carrier of infection are much smaller than in the case of raw, sweet milk. The presence of saprophytic bacteria in buttermilk may have some influence on pathogenic bacteria. Whether this influence is favorable or otherwise is difficult to det. by present bacteriological methods.

Studies on the physiology of metabolism of living plant cells. I. Absorption of lipocolloids in the plasma membrane. F. CZAPEK. *Prag. Intern. Z. physik. Chem. Biol.* 1, 108-23(1914).—A critical review of the theories of the relation of diosmotic metabolic exchange between the living protoplasm and the surrounding medium.

E. M. FRANKEL.

Studies on the physiology of metabolism of living plant cells. II. Changes in the permeability of the plasma membrane by potassium cyanide. MAX KREHAN. *Prag. Intern. Z. physik. Chem. Biol.* 1, 189-259(1914).—Dil. solns. of KCN act on the colloid of the plasma membrane, causing an increase in its permeability to certain substances. The increase in permeability to salts is dependent on the ions; for a given anion it increases in the order Na, K, NH_4 , Ca, and Mg, while for a given cation the order is NO_3 , Cl, acetate, citrate, and SO_4 . For polyatomic alcs. the order is glycerol, lactose, glucose, saccharose. There is no alteration for urea. The change in permeability is due to the CN ion and not to the alkalinity of the dissociated salt. The relation of permeability to concn. and time of action of KCN gave the typical adsorption-phenomena reaction-isotherms. The season of the year has some influence on the phenomenon, the reaction in the spring and winter being less marked and of shorter duration than in the summer. This cannot be explained as due to variations in light intensity. Temp. affects the reaction velocity but not the permeability. Dil. EtOH and CHCl_3 intensify the action of KCN while concd. solns. of narcotics antagonize it, diminishing the toxicity of the KCN and the narcotic as well. The latter findings would indicate that KCN and the narcotics have the same point of attack in the plasma membrane.

E. M. F.

The osmotic pressure of the juices of desert plants. J. A. HARRIS, J. V. LAWRENCE AND R. A. GORTNER. Cold Spring Harbor. *Science* 41, 656-8(1915).—The osmotic pressure of the juices of desert plants is much higher than that of plants in a more moist habitat. Of the former type 50% had an osmotic pressure of over 15.7 atms., while of the latter 50% had o. p. of 10.5 atms., or lower. Of the desert plants, 30% were over 20 atms., while in the other series only 3% reached this value. There is a higher max. and a higher minimum osmotic pressure in the desert plants.

E. M. F.

The toxicity of insecticides. C. W. WOODWORTH. Berkley. *Science* 41, 367-9(1915).—Five different species of tree scale were exposed to HCN vapor of various concns. for different lengths of time. Long-continued action at a strength below the lethal seems to have a benign influence on the scale. This may be explained by the increased production of antibodies or increased cell permeability or even utilization of the HCN by the insect, the latter suggestion being supported by some expts. showing an acceleration of the sprouting of seeds by dil. HCN solns.

E. M. FRANKEL.

Study of plant enzymes, particularly with relation to oxidation. A. D. HALL, E. F. ARMSTRONG, *et al.* *Rpt. Brit. Assoc. Adv. Sci.* 1913, 143-5.—Various studies on the relation of plant enzymes to pigmentation are reported. Sol. sap pigments appear to result from oxidation of a colorless chromogen by aid of an oxidase. With a minimum of water present the colored cell may be stimulated by a hormone with the result that the sap pigment is reduced to the colorless chromogen.

WM. P. GARRETY.

Some relations of plants to distilled water and certain dilute toxic solutions. M. C. MERRILL. *Science* 41, 176(1915).—Several factors cause the harmfulness of distd. H₂O to pea seedlings. Bacteria and fungi played an important part. The length of time the plants could grow in a culture soln. without change was detd.

J. J. SKINNER.

Electrolytic determination of exosmosis from the roots of anesthetized plants. M. C. MERRILL. *Science* 41, 176(1915).—Exosmosis was more rapid in the roots of *Pisum sativum*, when exposed directly to anesthetics, than where the roots were kept in H₂O during the exposure. There was a greater resistance to anesthetics by older plants.

J. J. SKINNER.

Direct assimilation of atmospheric nitrogen by plants. E. MAMELI AND G. POLLACCI. *Atti ist. botan. Univ. di Pavia* 14, 156-257(1914); *Ann. chim. applicata* 3, 67-9.—Extensive expts. have shown that the property of assimilating atmospheric N is not restricted to a particular class of plants, but is exhibited generally by all kinds of plants containing chlorophyll. The plants were grown in sterilized nutrient media free from N and the amt. of N combined was detd. by analysis of the plant and, in some cases, of the residual air. *Azolla caroliniana* and *Salvinia natans* were especially active in assimilating free N. It is suggested that the N combines directly with H in the cells containing chlorophyll, under the influence of an enzyme or a catalyst. M. X. S.

Smoke and gas poisoning of plants. L. J. KNIGHT AND W. CROCKER. *Botan. Gaz.; J. Roy. Hort. Soc.* 40, 184(1914); *Pharm. J.* 94, 699(1915).—Tobacco smoke is very injurious to seedlings of Leguminosae and Cucurbitaceae, producing chemotactic movements in the leaves of some species, and diseased growths in others. The leaves of *Mimosa pudica* and other leguminous plants fall off when exposed to tobacco smoke for 24-48 hrs. It also injures ferns and liverworts. CO is very toxic to plant life, and C₂H₄ especially so. 1 : 10,000,000 stops the growth of the epicotyl of the pea, 4 : 10,000,000 is markedly toxic, and 5 : 10,000,000 in 12 hrs. causes the open flower of the carnation to close. Thus, in smoke and illuminating gas, the heavy hydrocarbons are the plant poisons.

Degree of acidity of muscle under diverse mechanical conditions of contraction. F. PORCELLI-TITONE. Naples. *Intern. Z. physik. Chem. Biol.* 1, 338-53(1914).—The acid production in muscle is greatest in effective work. Lower values for H-ion concn. are obtained in isometric contraction, tetanus and isotonic contraction in the order named.

E. M. FRANKEL.

Capillary measurements on human serum and cerebrospinal fluid. B. KISCH AND O. REMERTZ. Cologne. *Intern. Z. physik. Chem. Biol.* 1, 354-88(1914).—Surface tension of normal human serum free from hemoglobin and chyle is constant. Heating the serum to 56-60° to inactivate it diminishes the surface tension. Age and sex have no effect on the surface tension of the serum or cerebrospinal fluid. Normal values are obtained in functional psychoses, alcoholism, dementia praecox, paralysis, tabes, epilepsy and pregnancy. Fetal serum gives lower values. Low values were also obtained from epileptics during a fit, a case of uremia and one of icterus. The surface tension of the cerebrospinal fluid is generally constant, being diminished in cases of icterus, uremia and apoplexy. E. M. FRANKEL.

Osmotic properties of different kinds of muscle. E. B. MÆIGS. Philadelphia. *Science* 41, 689-91(1915).—M. takes exception to some of the conclusions of the expts. of v. Kőrösy (*C. A.* 9, 634) and maintains that striated and non-striated muscle have different osmotic properties and that these are not due to injury in the process of prepn. (cf. *C. A.* 8, 1170). E. M. FRANKEL.

Effect of repeated injections of pituitrin on milk secretion. S. SIMPSON AND R. L. HILL. *Am. J. Physiol.* 36, 347-51(1915).—Injection of pituitary exts. causes in goats a marked increase in the amt. of milk secreted and also in its fat content. Injections repeated over a period of several months lead to the establishment of an immunity against this action. (Cf. following abstr.) J. F. LYMAN.

Mode of action of pituitary extract on the mammary gland. S. SIMPSON AND R. L. HILL. Ithaca. *Quart. J. Exp. Physiol.* 8, 377-8(1915).—The flow of milk, which follows the injection of pituitary ext., is apparently due to the action of the ext. on the secretory mechanism of the gland and not on its muscular tissue, since BaCl₂, which is a specific stimulant for muscle, produces no increase in milk flow. Cf. preceding abstr. V. C. M.

Note on paper by Simpson and Hill: "The mode of action of pituitary extract on the mammary gland." E. A. SCHÄFER. Edinburgh. *Quart. J. Exp. Physiol.* 8, 379-81(1915); cf. preceding abstr.—It seems probable to Schäfer that pituitary acts by promoting contraction of plain muscle in the alveolar walls. V. C. M.

The metabolism of the amino acids in the organism. I. Action of muscular tissue on the amino acids added through the circulating blood. UGO LOMBROSO. *Atti accad. Lincei* 24, I, 57-62(1915).—It is concluded that when blood containing a large amt. of amino acids (about 1%) is circulated through the muscles of a dog there is always a diminution of amino acids after the circulation. Of these amino acids the greater part is found deposited unchanged in the tissues. Of the remainder a part is burned (as was shown by an increase of NH₃) and a part is utilized to form compds. not titratable with formol. The significance of these observations will be discussed in a subsequent paper. **II. Action of muscular tissue on amino acids circulating in Ringer solution.** *Ibid* 148-53.—Causing amino acids dissolved in Ringer soln. to circulate in muscular tissue always induces a more or less notable diminution (up to 12%) in the amino acid content of the nutrient liquid. Besides the percentage diminution of the amino acids in the liquid circulated through the muscular tissue there is a diminution in the amt. of the liquid recovered, which causes a conspicuous edema. Thus the total amt. of amino acids lost both by the percentage diminution of amino acids in the soln. and by the diminution of liquid recovered amts. to about 50% of that used. The amino acid content of the muscles was detd. before and after the circulation and it was found that nearly all of the above 50% was deposited in the tissues and remained unchanged. The amt. of amino acids not recovered amounted to 1-2% but it could not be detd. whether this was all due to exptl. error or not. E. J. W.

Function of the suprarenals. I. General considerations and biochemical investigations. C. CIACCIO. Univ. Palermo. *Arch. exp. Path. Pharm.* 78, 347-69 (1915).—The suprarenal is the seat of an active lipoid metabolism. Besides a review of the other work C. offers the following evidence.: the suprarenal contains free choline and related compds., simple compds. contg. P and a phosphatase. C. J. WEST.

Condition of phosphorus and of calcium in milk (LINDET) 12.

G. PATHOLOGY.

H. GIDEON WELLS.

Adsorption of toxins by animal charcoal. R. KRAUS AND B. BARBARA. *Deut. med. Wochschr.* 41, 393-4(1915).—Diphtheria toxin (dild. 1 : 10) was shaken with animal charcoal (Merck) and after standing 1 hr. at 37° was injected subcutaneously into a guinea pig of 250 g. The animal survived without even showing a local edema. A control succumbed to $\frac{1}{100}$ of the dose in 48 hrs. Similar results were obtained with tetanus and dysentery toxin. S. AMBERG.

Experimental data concerning the action of benzene. W. NEUMANN. *Deut. med. Wochschr.* 41, 394-6(1915).—Rabbits were treated with pure benzene. Benzene is a leucotoxin of powerful action, but its action is not uniform. There are great individual variations. S. AMBERG.

Clinical studies with the Abderhalden dialysis method. H. STEINER. *Deut. med. Wochschr.* 41, 489-92, 526-8(1915).—The Abderhalden dialysis method is of importance clinically to differentiate diseases here and there. A final judgment concerning its applicability cannot be given as yet. S. AMBERG.

Further experimental investigations concerning the specificity of the protective enzymes by means of the optical method. H. JAFFÉ AND E. PRIBRAM. *Münch. med. Wochschr.* 62, 614(1915); cf. C. A. 9, 930.—The serum of a rabbit treated with cancer emulsion changed the rotation of a mixt. of serum and cancer peptone but not of serum and placenta peptone. Inactivation of this serum by heating it to 58° for $\frac{3}{4}$ hr. suppressed its action on cancer peptone. Addition of 0.2 cc. guinea-pig serum to the inactivated serum made it behave as before inactivation. Guinea-pig serum (0.2 cc.) had no effect on the cancer peptone. In former expts. it was shown that treatment with placenta peptone yielded a serum decomposing placenta and silk but not cancer-peptone. Inactivation of such serum with addition of 0.2 cc. fresh guinea-pig serum gave the same results. The reactivation does not injure the specificity of the reaction. S. AMBERG.

Butyric acid and sclerosis. G. E. COLEMAN. Paris. *Ann. inst. Pasteur* 29, 139-56(1915).—In a study of the relation of the butyric acid absorbed from the alimentary tract to sclerosis of the arteries, guinea pigs were used because of the more frequent arterial lesions in the herbivora. Since very small quantities of the free acid had to be given to the animals, it was decided to use Ca butyrate, which was tolerated much better. The excess of Ca thus introduced was thought also to favor the production of lesions. The butyrate was introduced subcutaneously, intraperitoneally and also by mouth. In view of the small quantities of acid endured by the animals and the limited number of animals studied, and keeping in mind the fact that spontaneous sclerosis occurs in a large proportion of normal guinea pigs, no definite conclusion is drawn concerning the action of free butyric acid. The author believes that the ingestion of Ca butyrate in the doses used produces in the aorta and the other organs of guinea pigs a generalized sclerosis, but not atheroma. G. T. C.

Attempt to discover the composition of tissue fluid in normal and nephritic animals. A. E. BOYCOTT AND J. S. C. DOUGLAS. Univ. Manchester. *J. Path. Bact.* 19, 528-48(1915).—The normal blood of rabbits contains about 0.55% NaCl, the plasma 0.65%

and the corpuscles 0.3%. Blood was removed from one carotid, and into the other was immediately injected 4 cc. of 60% aq. dextrose soln. per kg. body wt. Ten sec. after injection the animal was bled freely. The liquid brought into the blood from the tissues by this intravascular injection contains some protein and 0.5% NaCl. The liquid similarly obtained by the use of Na_2SO_4 contains about 0.35% NaCl, and the liquid which comes in to replace blood lost by hemorrhage, from 0.4 to 0.7% or more. The liquid thus obtained can be regarded as representing tissue fluid. Some differential filtration by the capillary wall must be assumed. In rabbits with U-nephritis the liquids obtained in parallel expts. contained more protein and more chlorides than in normal animals. The difference probably signifies a difference in the compn. of the tissue fluid.

JOHN T. MYERS.

Use of a suprarenal antigen in the Wassermann reaction. A. SÉZARY AND P. BORRL. *Compt. rend. soc. biol.* 76, 334-5 (1914).—The use of a suprarenal antigen was suggested by reason of the high content of cholesterol and lecithin in suprarenal ext. The suprarenals from freshly killed cattle were freed from surrounding fat, cut in thin strips, washed rapidly with sterile, physiol. serum and pounded in a mortar to a homogeneous pulp; the latter was distributed in Petri dishes and dried *in vacuo* over H_2SO_4 . After 24-48 hrs. the product was finely pulverized in a mortar and the resulting powder was passed through a sieve. Two exts. were prepd. by digesting 5 g. suprarenal powder in 100 g. abs. alc. and 100 g. alc.- Et_2O , resp., for 8 days. The supernatant liquid was decanted, preserved in an ice box and dild. 1 : 20 with physiol. serum when desired for use. The 2 exts. gave comparable results, so only the pure alc. ext. was prepd. thereafter. This antigen exhibited properties which were very frequently identical with those shown by a tested syphilitic liver ext.; the degree of hemolysis (measured by means of the Vernes scale) was quite often analogous in the 2 cases. It is concluded that this suprarenal antigen may be substituted for the usual antigens in the Wassermann reaction. Inasmuch as the chem. comp. of the suprarenals appears to be practically const. in animals killed in abattoirs, it appears probable that there may be readily prepd. therefrom an antigen which will be of const. sensitiveness and which will yield comparable results in the hands of different observers. It will be shown in a succeeding note that fixation of complement in the presence of this antigen is not influenced by the functional or anatomical condition of the suprarenals (especially by a condition of suprarenal insufficiency) of the subject whose humoral fluids constitute the object of study.

H. S. PAINE.

Significance of the Abderhalden method. N. KOCHNEV AND A. CHINGAREVA. Petrograd. *Compt. rend. soc. biol.* 76, 354-7 (1914); cf. *C. A.* 8, 3590.—The specificity of the Abderhalden reaction was tested in a series of more than 50 cases of various diseases (nephritis, acromegaly, Basedow's disease, cancer, pernicious anemia, hepatic cirrhosis, etc.). The reactions with kidney, heart, placenta, liver, lungs, brain, suprarenals, etc., are tabulated for some of the various diseases. For instance, the serum of cancerous patients always gave a positive reaction with carcinoma and a negative reaction with placenta. The serum of Basedow patients always gave a positive reaction with the thyroid, while the sera of acromegaly patients and cirrhotics reacted with the hypophysis and liver, resp. In the case of nephritics the reaction was positive not only with the kidney, but also with the heart and placenta (often most intense with the 2 latter). The placenta gave a negative reaction with the serum in the case of all the other affections. The above connection between nephritis and the reaction with placenta may possibly have some bearing on the occurrence of nephritis during pregnancy. With helminths the reaction was positive in the case of subjects infected with these parasites and negative with non-infected subjects; this was evidently a group reaction, however, for the sera of patients suffering from helminthiasis (*Taenia saginata* and

Botriocephalus latus) gave a positive reaction not only with the parasites with which they were infected, but also with other species of *Taenia*, and even with horse ascarides. Regarding the specificity of the Abderhalden reaction it is concluded that the latter is, at least in certain cases, merely a group reaction (comparable to the phenomenon of agglutination, for instance).
H. S. PAINE.

Gastrointestinal studies. V. The protein curve of gastric digestion in normal and pathologic cases. J. A. CLARKE AND M. E. REHFUSS. Jeff. Med. Coll., Phila. *J. Am. Med. Assoc.* 64, 1737-41(1915); cf. *C. A.* 9, 932.—“The gastric juice in health shows definitely a protein content of very low degree. This content is increased in disease by the addition of an exudation of protein materials from inflammatory, ulcerous, or carcinomatous mucous membranes, or by the addition of partially digested and retained food residues, or the swallowing of protein material such as certain forms of sputum. Bread and tea alone, following the comp. of the Ewald meal, will show in the absence of any pathologic factor a definite amt. of protein corresponding to the curve or the digestive power of the juice secreted. A mixt. or maceration of bread in tea will show a protein content on 1 : 20-1 : 40; if the mixt. is acted on by an artificial gastric juice *in vitro* the protein content of the juice rises steadily within the next 2 hrs. and may reach 1 : 320 in 75 min. The pathologic significance arises when a curve shows any marked deviation from this recognized standard, that is when there is an undue conc. of protein out of all proportion to that normally found at that particular phase in digestion. If therefore a marked increase in protein does not conform in a general way to the acid curve it can be definitely stated that the protein is coming from other sources than the proteins of the bread. Normally this protein is of the nature of a proteose, but in inflammatory or ulcerative conditions it is probably serum protein removed to a large extent by satn. with $(\text{NH}_4)_2\text{SO}_4$. In the differentiation of achylia and carcinoma, the test is of value in direct proportion as the case approaches a true achylia and the added factors such as swallowed pus, bleeding and protein residues can be ruled out.
L. W. RIGGS.

Form of diabetic coma not due to “acetone bodies.” J. ROSENBLUM. Pitts-burgh. *Penn. Med. J.* 18, No. 17(1915); *J. Am. Med. Assoc.* 64, 1879.—The 3 cases studied by R., which differed so completely from the modern idea of acidosis as the cause of coma, were all of the severe type, with no tolerance for carbohydrates; and with a restricted protein intake there was no lessening of the glucose output. The urine contained a normal amt. of ammonia N and showed no trace of acetone, diacetic acid or β -hydroxybutyric acid. There was no evidence of any kidney pathology. The urine contained excessive amts. of colloidal N, neutral S, and amino acids. Death occurred in typical diabetic coma. R. suggests that more attention be paid to the study of the excretion of amino acids, polypeptides and certain unknown substances in this disease.
L. W. RIGGS.

Oxygen and carbon dioxide in the blood in uricacidemia. L. PRETI. *Riforma medica* 31, No. 16(1915); *J. Am. Med. Assoc.* 64, 1884.—P. shows that by artificial circulation of oxygenated blood through a liver containing uric acid, the latter is destroyed, but may be reformed by circulating blood containing CO_2 . Both phenomena are the work of enzymes in the blood. Animals breathing air with much CO_2 eliminate larger amts. of uric acid through the kidneys, and the uric acid content of the blood is higher. A study of 12 persons with attacks of gout, tophi, and high uric acid content of the blood showed their blood to contain on the av. about $1\frac{1}{2}$ the O of blood of healthy controls, while CO_2 in the blood of gouty persons averaged 50% higher than in that of controls. These findings throw light on the familiar experience that gout affects persons with defective oxidations owing to a sedentary life, muscular inanition, depression of heart action, etc.
L. W. RIGGS.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

The local action of lead. F. A. McJUNKIN. *J. Med. Res.* 32, 271-81(1915).—Within endothelial leucocytes and endothelial cells inorganic lead is changed to a compd. that is sol. in albuminous fluids, in which form it passes into the blood, producing a "stippling" of the corpuscles, and into liver cells, producing in them a basophilic granulation. The basophilic hyaline change in these cells is due to the immediate presence of lead as shown by subjecting the preps. to prolonged treatment with an alkali sulfide. Lesions other than those at the site of application and the basophilic granulation of the liver cells and red blood corpuscles were not produced in animals even in cases of administration of lead for periods of some months. GEO. T. CALDWELL.

The effect of phosphorus poisoning upon the peroxidase reaction of rabbit liver. C. H. BUNTING AND P. K. RAND. *Univ. Wisc. J. Med. Res.* 32, 283-6(1915).—To test the effect of P-poisoning upon the peroxidase of the liver, rabbits were poisoned by the subcutaneous injection of various amts. of a 1% soln. of P in olive oil. Aq. exts. of the livers of the poisoned and also of normal animals were tested quantitatively for peroxidase by means of the phenolphthalein reagent of Kastle and Shedd. In the poisoned animals the peroxidase seemed to be reduced or its action inhibited or destroyed, even to the point of complete disappearance, depending upon the dose of the poison administered. This reduction occurs prior to the accumulation of fat in the organ and may possibly be the cause of such accumulation in later stages.

GEO. T. CALDWELL.

The pharmacological properties of diallylmalonylurea (dial). LUIGI CASTALDI. Florence. *Arch. farm. sper.* 19, 289-306(1915).—Diallylmalonylurea, when injected into frogs and rabbits or administered orally to man, produces sleep without any noteworthy post-hypnotic phenomena. The effect is produced with smaller doses than with the other hypnotic derivs. of barbituric acid, on account of the greater mol. wt. of the allyl group. It acts by exciting the inhibitory centers of the heart. No advantages are claimed for this drug over the other hypnotics of the *ureid* series. A. W. DOX.

Levorotatory sodium glycerophosphate. L. MAESTRO AND L. CASTALDI. Florence. *Arch. farm. sper.* 19, 352-66(1915).—Sodium *l*-glycerophosphate, administered subcutaneously, is completely absorbed and produces a diminution in P excretion.

A. W. DOX.

Colloidal state of alkaloids. The relation between surface tension and size of particles and toxicity. I. TRAUBE AND N. ONODERA. Charlottenburg. *Intern. Z. physik. Chem. Biol.* 1, 35-59(1914).—Aq. solns. of free alkaloids whose mol. wts. exceed a certain limit are colloidal. The surface tension of such a soln. is lower than that of pure H₂O and the lowering of the surface tension is proportional to the toxicity to tadpoles and fish, so that the toxicity may be measured with a stalagmometer. Some alkaloidal solns. are not stable and the size of the particles and the surface tension increase with a corresponding decrease in the toxicity. The surface tension is altered by change in temp. or addition of antagonistic substances or acids. The authors regard the decrease of surface tension and the size of the particles as a method of increasing the reaction velocity and in this case the toxicity. Local action of alkaloids is a result of an increased alkalinity at a given place with the liberation of free alkaloid in the colloidal state, etc.

E. M. FRANKEL.

Studies on narcosis. I. Effect of ethylurethan and chloral hydrate on the carbon dioxide production in the nerve fiber. SHIRO' TASHIRO AND H. S. ADAMS. Chicago. *Intern. Z. physik. Chem. Biol.* 1, 450-62(1914).—CO₂ production is greatly diminished when a nerve is narcotized with chloral hydrate or ethylurethan in concs. which pro-

duce a reversible loss of excitability. With weak concs. of these narcotics the CO_2 output is increased, probably due to the increased irritability of the nerve. Certain nerves were found to be unexcitable and in these cases the metabolism was abnormally low. The metabolism of the nerve is interfered with by narcotics and there is a parallelism between the CO_2 output and the state of excitability. Narcotics may primarily affect protoplasm by lowering its metabolism with a corresponding loss of irritability.

E. M. FRANKEL.

Effect of arsenic compounds on the Rous chicken sarcoma. CASIMIR FUNK. *J. Exp. Med.* 21, 574-5(1914); cf. *C. A.* 9, 1936.—Arsenic and arsenious acids, cacodylic acid, atoxyl and neosalvarsan fail to influence markedly the growth of the Rous chicken sarcoma.

G. M. MEYER.

Influence of digitalis on the T wave of the human electrocardiogram. ALFRED E. COHN, FRANCIS R. FRASER AND ROSS A. JAMIESON. Rockefeller Inst. *J. Exp. Med.* 21, 593-604(1915).

G. M. MEYER.

Further experiments on the effects of long-continued intraperitoneal injections of proteins. PAUL G. WOOLLEY, AMIE DEMAR AND DAISY CLARK. Univ. Cincinnati. *J. Exp. Med.* 22, 114-21(1915); cf. *C. A.* 9, 932.—An attempt was made to discover whether or not certain protein materials, such as albumose, casein and albumin, when introduced parenterally (peritoneally) into exptl. animals, are able to produce organic lesions. These proteins were used alone or in combination with CHCl_3 which was administered in oil and as an anesthetic. The results were negative.

G. M. MEYER.

Late poisoning with chloroform and other alkyl halides in relationship to the halogen acids formed by their chemical dissociation. EVARTS A. GRAHAM. Rush Medical College, Chicago. *J. Exp. Med.* 22, 48-75(1915); cf. *C. A.* 9, 934.—The central lobular necrosis in the liver, which has been regarded as characteristic of late CHCl_3 poisoning, has been produced experimentally by a number of other drugs. It is, therefore, in no sense peculiar to CHCl_3 poisoning. The drugs used were: CH_2Cl_2 , CCl_4 , CHBr_3 , CHI_3 , $\text{C}_2\text{H}_5\text{Cl}$, $\text{C}_2\text{H}_5\text{Br}$, $\text{C}_2\text{H}_5\text{I}$, $\text{C}_2\text{H}_5\text{Br}$, or in general, the halogen substituted aliphatic hydrocarbons with 1 or 2 C atoms. The mechanism by which CHCl_3 produces its characteristic tissue changes must accordingly be considered as a group reaction. The view is developed that the changes characteristic of late poisonings with the above substances, namely, edema, multiple hemorrhages, fat infiltration and necrosis are ascribable (1) to acids and (2) to the fact that the amt. of acid formed parallels the chem. dissociability of the drug outside of the body. All the characteristic features of late CHCl_3 poisoning have been produced merely by administration of HCl , except for a different distribution of the liver necrosis. The areas of central necrosis produced in the liver by various substances under discussion give an acid reaction to neutral red. Na_2CO_3 in a hypertonic NaCl soln. markedly inhibits the production of lesions. After the administration of some of these drugs there has been an increase of the neutral salts of the halogen acids in the urine. The necrosis-producing powers of CH_2Cl_2 , CHCl_3 and CCl_4 parallel the amts. of HCl which these substances theoretically can yield in their breakdown outside of the body. Ether and chloral hydrate which do not yield halogen acid likewise do not produce necrosis. They only induce edema and fat infiltration to a less marked degree. The halogen acid, directly liberated in the process of dissociation, may be the important factor which makes the tissue changes seen in poisoning with CHCl_3 and other alkyl halides so different from those following the administration of narcotic drugs of a different type.

G. M. MEYER.

Phenylacetylglutamine and its formation in the human body after feeding phenyl-

acetic acid. H. THIERFELDER AND C. P. SHERWIN. Univ. Tübingen. *Z. physiol. Chem.* 94, 1-9(1915); cf. *C. A.* 9, 86.—Phenylacetylglutamine (A) shows $[\alpha]_D^{17}$ —18.1, $[\alpha]_D^{18}$ —18.4 in H_2O , $[\alpha]_D^{18}$ —19.6 in HCl . The synthetic product, obtained in a yield of 34-60%, shows $[\alpha]_D^{17}$ —17.9°. Phenylacetylglutamine-urea, $[\alpha]_D^{16}$ —13.97°, $[\alpha]_D^{17}$ —14.28°. Phenylacetylglutaminic acid, needles from H_2O , m. 123°, $[\alpha]_D^{18}$ —19.16°. *Polassium salt*. *Brucine salt*, cryst. Phenylacetylglutaminic acid is excreted as such from the human body. No trace of (A) was found. G. M. MEYER.

Analytical investigation of combined magnesium-neuronal hypnosis. P. GENSLER. Univ. Zürich. *Arch. exp. Path. Pharm.* 78, 317-30(1915).—In Mg narcosis there is no increase over the normal Mg content of the brain in either the rabbit or dog. In the combined Mg-neuronal hypnosis the brain contains nearly the same percentage of neuronal as in neuronal sleep. Thus the penetrability of the cell-membrane is not changed by the injection of Mg. The Mg does not seem to produce a more rapid action of the neuronal or an essential deepening of the sleep. The paralysis of the muscles and the narcotic action are more noticeable and the recovery is slower after the combination narcosis. Thus, analytically and functionally, it seems to be a pure addition reaction. The content of neuronal in the intestinal canal is increased after the combined effect, being 22.3% as against 6.5% in the normal neuronal sleep.

C. J. WEST.

The action of several heart drugs (strophanthin, caffeine, diuretin) upon the coronary vessels. S. SAKAI AND S. SAN'EYOSHI. Freiburg. *Arch. exp. Path. Pharm.* 78, 331-46(1915).

C. J. WEST.

Action of quinine upon the striated muscles of the frog. KNUD J. A. SECHER. Univ. Copenhagen. *Arch. exp. Path. Pharm.* 78, 445-54(1915); cf. *C. A.* 8, 3472.—Quinine salts (1 : 250) destroy the striated muscles of frogs. Weaker solns. do not cause a histological change. The compd. formed between quinine and the muscle substance is reversible. Quinine accelerates the production of fatigue in these muscles, and decreases the amt. of work performed. The action of quinine is unlike that of caffeine.

I. ZOÖLOGY.

R. A. GORTNER.

Researches on hemolysis. I. Hemolysis by capillary-active substances in cold-blooded animals. B. KISCH. Naples. *Intern. Z. physik. Chem. Biol.* 1, 60-81(1914).—Hemolysis of the erythrocytes of *Sipunculus midus*, *Seyllium calulus*, *Torpedo marmorata*, *Scorpena scropa*, *Lophius piscatorius*, *Labrus tardus* and *Labrus festiosus* by means of solns. of $MeOH$, $EtOH$, $PrOH$, $iso-BuOH$, $iso-C_4H_{11}OH$, Et_2O and Me_2CO of definite concn. and surface tension showed no relationship between the hemolysis and the capillary activity of the liquids. The hemolyzing concns. are lowest with *Sipunculus* and highest with the teleosts. No const. difference in the surface tension of the blood serum of males and pregnant females of the same species could be demonstrated. It appears that the lipid solubility of the substances is of importance in hemolysis.

E. M. FRANKEL.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

The new formulation of the food law (German). A. BRYTHIEN. *Z. Nahr.-Genussm.* 28, 575-84(1914).—Two parties have been formed in Germany upon this issue. One of these, comprizing the officials and majority of associations of interested manufacturers and dealers, favor the appointment of the Kaiserliche Gesundheitsamt

as an institution empowered legally to prescribe methods of prepn. and to adopt definitions, methods of analysis, and standards for all kinds of food products, the regulations so established to be enforced uniformly throughout the Empire and to replace the often contradictory requirements now prevailing in the different administrative divisions of the country. The second party, comprizing a minority of interested industrial bodies, seeks to attain the same end by means of an elective board or central bureau, the members of which are to be elected by associations of manufacturers and dealers, each class of food products to be represented by a fixed number of delegates, these delegates to act as an executive council to a limited number of official scientific experts by whom regulations similar to those provided in the first plan are to be promulgated and by whom all questions arising under the law are to be decided.

A. F. SEEKER.

Sensitive and rapid method for detecting the presence of sodium hydrogen sulfite in meat. FOLCK AND FARRERAS. *Boll. chim. farm.* 53, 106(1914).—Iodate starch paper is prepd. as follows: *Soln. (I)*: Add 95 g. distd. H_2O to 2.5 g. starch and heat gradually with const. stirring so that the starch is thoroughly fluid by the time the liquid begins to boil. *Soln. (II)*: 1 g. $NaIO_3$, 2.5 g. citric acid and 5 g. distd. H_2O . Mix *Solns. (I)* and *(II)* thoroughly in the cold and absorb with strips of filter paper. When dried under conditions that preclude the direct action of sunlight and gases and vapors of the laboratory, this reagent paper remains perfectly white. $NaHSO_3$ may be detected in meat by means of the action of liberated SO_2 on $NaIO_3$ in the presence of moisture. Macerate 5–15 g. meat for 5 min. in sufficient H_2O to cover the mass, remove the meat and test the liquid with the iodate starch and paper. A blue coloration is produced in case $NaHSO_3$ was present in appreciable amt. This method is compared with the Rosell procedure which consists in testing the liquid obtained by macerating meat in H_2O with a 1% $KMnO_4$ soln.; the latter is decolorized if sufficient $NaHSO_3$ was present.

H. S. PAINE.

Detection of antiseptics (benzoic acid and its derivatives) in preserved meats. F. MARRE. *Ann. fals.* 8, 16–27(1915); *J. Soc. Chem. Ind.* 34, 298(1915).—Two samples of a German preservative, "Cordin" consisted of: (1) *m*-dinitrobenzoic acid, cinnamic acid, and $NaCl$; (2) $NaCl$ 20, KNO_3 35, and an amino deriv. of $BzOH$ 45%. Samples of canned meats imported into France from Germany and America were all free from $BzOH$, salicylic acid, $HCHO$, Na_2CO_3 , and fluorides, but derivs. of $BzOH$ were found in 2 cans of corned beef, 2 of lunch tongue, and in various sausages. The following method is recommended: Dry 20 g. mixed with sand and ext. with benzene or CCl_4 to remove the fat. Drive off solvent, ext. with hot H_2O and shake out the H_2O soln. with Et_2O . Evap. off Et_2O and dissolve in a small quantity of aniline faintly colored with magenta, adding enough H_2O and HCl to dissolve the aniline. Filter and wash the filter with H_2O . If $BzOH$ derivs. are present, the filter paper will be blue. $BzOH$ may be detected in the presence of nitrates by extg. the meat with H_2O , evapg. the ext. to a small vol., then transferring to a test tube and carrying the evapn. to dryness. Heat the residue to incineration, with the production of bitter almond odor if $BzOH$ derivs. be present.

H. S. BAILEY.

Effervescing beverages. L. GAUCHER AND F. GEORS. *Ann. fals.* 8, 94–8(1915).—G. and G. studied the bacteriol. flora ordinarily found in these liquids, and also those pathogenic organisms which are accidental. Total counts were taken and the saprophytes detd. *B. subtilis* is most common. *B. mesentericus*, *B. aerophilus*, *B. translucidus*, *Dip. roseus*, and *M. cinnabareus* are also found. *B. coli* and *B. typhosus* have never been found in the raw water. However, *B. coli* and *B. typhosus*, if inoculated into lemonade, will increase rapidly for the first 15 days, then die off. The flora were found to differ from winter to summer.

C. S. MUDGE.

Apple sirup and concentrated cider. H. C. GORR. *Yearbook of Dept. Agr.* 1914, 227-44.—G. describes the following processes for the utilization of surplus and cull apples: (1) *The production of apple sirup.* The apple juice is almost neutralized with CaCO_3 or $\text{Ca}(\text{OH})_2$, and after the addition of infusorial earth is filtered through a plate and frame filter press. The filtered juice is then concd. to the desired consistency and cooled quickly to 71° . After the deposition of the Ca malate crystals the sirup is drawn off into containers and sterilized. (2) *Concentration of sweet cider by freezing.* The fresh cider is frozen in tin-lined ice cans in the brine tanks of an ice-making plant. The frozen cider is thawed at the sides and bottom and crushed with a power ice crusher. The sirupy part is then sepd. by means of a standard sugar centrifugal machine. The sirup obtained is again frozen and the process repeated. The concd. product in sealed containers will keep for weeks in a refrigerator or at cold room temp. It gradually ferments if allowed to become warm, but will spoil much more slowly than ordinary cider. One gal. of this sirup represents 5 gals. of the original cider. P. J. DONK.

Detection of potatoes and potato products. D. SCHENK AND H. BURMEISTER. *Apoth. Ztg.* 30, 234(1915).—As a result of recent Ger. regulations respecting the use of potato flour in bakers' products, preliminary expts. were undertaken to det. whether or not potato albumin is capable of reacting as a precipitin and of producing such bodies or an antiserum, by means of which the detection of potato albumin as such and of potatoes in bakers' products may be possible. It was found by expt. that potato albumin, as also that of other plants, when introduced into the blood of the rabbit brings about the formation of precipitins capable of effecting pptn. in fresh potato juice. Tests were likewise made on denatured potato albumin (after conversion into its alkali albuminate) and showed that a soln. of the latter was indifferent toward the antiserum previously used. The work is being continued. W. O. E.

Drying of potatoes. G. FISCHER. *Z. Ver. deut. Ing.* 59, 353-62(1915).—The technical problems involved in the use of potato driers, adapted for the particular method used, are indicated. The important drying app. and accessory machines used for the drying of sliced or mashed potatoes are described and numerous illustrations shown. The methods of prep. of the potatoes and the drying are given in a detailed description. Experimental data shows that the heat efficiency for drying ovens adapted for sliced potatoes and those for the mashed potatoes is approx. the same.

H. R. GUNDLACH.

Microscopic detection of the addition of potato to bread. W. HERTER. *Mikrokosmos* 1914-15, 237-9.—A small piece of bread crumb is moistened with H_2O , placed on a microscopical slide and worked into a paste with the cover glass. The starch originating from raw ground potatoes is distinguished from the starch obtained from boiled and crushed potatoes and potato flakes by the fact that the starch granules in the former case are egg shaped, ellipsoidal, highly refractive bodies, three or four cornered, smooth surface and with deep furrows running lengthwise and resembling brain formation. Their size varies from a few μ to μ 150 with an average at 100μ . Where boiled potatoes have been employed in some form the characteristic starch granules are absent, having been gelatinized, and these "gelatinized cells" are present in the baked loaf. Their general contour is round or elliptic. They are only slightly refractive and as a rule yellowish in color and transversed by numerous delicate veins. Their size varies between 100 and 300μ . The identification of potato constituents is facilitated by staining with a weak soln. of methylene blue or gentian violet: Rye starch = colorless, p. starch slightly colored, "gelatinized cells" strongly colored. Alk. soln. of Congo-red: Rye starch = pink, p. starch = colorless, "gel. cells" = deep purple-red. Albumen particles, peelings, etc., the former being colored brick-red by Congo-red, can be differentiated from the "gelatinized cells" by their torn appearance and irregular size and

shape. Whenever it is necessary to make a quant. exam. 10 different fields should be examd., counts carefully made and an average arrived at. It is permissible to express the results in terms of parts by wt. Microscopical pictures are given.

C. A. NOWAK.

Protein charts. A. SILVERMAN. Univ. Pittsburgh. *J. Ind. Eng. Chem.* 7, 533-4(1915).—In the detn. of protein in feeds, NH_4 is distd. into 25 cc. 0.2 N acid and the excess acid titrated with 0.2 N alkali. S. has prepd. for different moisture contents curves in which % of crude protein is plotted against cc. of 0.2 N alkali. From these charts the protein content can be read directly. Three of the curves in use are shown.

ISADOR MILLER.

The chemical examination of ghee. K. H. VAKIL. *J. Soc. Chem. Ind.* 34, 320 (1915).—Indian ghee is obtained from either cow or buffalo butter. Analyses made by others are summarized and a table given showing butyro-refractometer reading, sapon. no., R.-M. no., and acid no. (not oleic) of 10 authentic ghees. The greatest variation is in the R.-M. no., that of Menon (18.24) being probably too low, due to overheating in drying the sample. V.'s limits are 25.51 to 20.46. High acid values indicate that the sample is old. The figs. for free acid given by V. are lower than usually reported.

H. S. BAILEY.

Report of work in the field of milk chemistry and dairying during 1913. W. GRIMMER. *Milchwirtsch. Zentr.* 43, 530-35, 551-6, 569-72(1914); 44, 3-8, 17-23, 33-4(1915); cf. C. A. 9, 1809.

G. A. MENGE.

The condition of phosphorus and of calcium in milk. LINDER. *Ann. de l'inst. national agron.* 1912; through *Milchwirtsch. Zentr.* 44, 86-7(1915).—(1) The sol. caseins of milk can be detd. by pptn. with a satd. soln. of phenol or with a mixt. of phenol and HgSO_4 . (2) The total amt. of sol. caseins is very uniform, but their relative amts., detd. by means of the polariscope, vary in different milks within wide limits. (3) The presence of sol. caseins in serum is caused by the solvent action of phosphates, citrates, alkali chlorides, lactose, etc., in milk. (4) The sol. caseins adhere to the solid particles of casein that are present in suspension, the more strongly when the latter contain water; these solid casein particles enclose a concd. soln. of the sol. caseins when they are held in the serum itself; when through coagulation they are brought together, the enclosed caseins are released. The cheese-curd furnishes, according to the degree of drainage, larger or smaller amts. of sol. caseins for the nutrition of different micro-organisms. Cheeses undergo fermentation more quickly and vigorously, the greater the water content. (5) With an acid soln. containing 1.25% of phenol, one can ascertain by pptn. which casein is the more abundant in the mixt. (6) Careful coagulation of serum by heat furnishes a coagulum in which both caseins are present in the same proportions as in the serum from which they were obtained. (7) CaCl_2 , added to milk before coagulation, changes the phosphates and citrates of the alkalies into Ca salts; the sol. caseins lose a part of their solvent and increase the N content of the coagulum. (8) The di-Ca phosphate formed is decomposed by water and forms CaHPO_4 , which by continuous transposition takes the Ca from the casein, and the casein is in consequence pptd.; Ca phosphate, corresponding to the amt. of Ca contained in the casein, is formed. (9) The addition of CaCl_2 will on this account appreciably increase the yield of cheese. (10) By their solubility or insolubility in the presence of CaCl_2 , by their capillary attraction for insol. casein, by their pptn. with phenol, by their slight coagulation with heat, these two caseins are shown to behave similarly, and milk albumin may be regarded as a casein. (11) The condition shown by the milk proteins is simple: the β casein (pseudo-albumin) is present in so small an amt. that it is completely dis-

solved in the serum, while only one-tenth of the other or α casein is in soln. and the remaining protein is in colloidal soln.

I. L. VAN SLYKE.

The freezing point of milk considered in its relation to the detection of added water. G. W. MONTER-WILLIAMS. *Rept. of Local (Brit.) Gov. Bd., Food Rept. No. 22, 1-32* (1914); *J. Soc. Chem. Ind.* 34, 444 (1915).—A study of the factors, e. g., supercooling, rate of stirring, etc., influencing the correct detn. of the f. p. of a soln., followed by a detailed description of W.'s f. p. app. This app. is essentially an Et_2O bath contained in a large Dewar tube. The temp. of the bath is controlled by exhausting the air space above the Et_2O , or drawing in fresh Et_2O when the bath gets too cold. The f. p. of milk samples may be compared with that of a soln. of 9.495 g. of pure sucrose in 100 g. of H_2O , which has a f. p. of -0.5345° , the av. f. p. of normal milk. In practice an ice-salt bath may be used, with the temp. as low as -5° without materially affecting the results. The removal of fat does not appreciably affect the f. p. of milk, but any considerable amt. of acid does. The increase in acidity is normally slow, and if a sample does not taste sweet the f. p. method is applicable for the detn. of added H_2O . The av. f. p. of 141 samples of genuine milk was -0.5345 , max. -0.558 , min. -0.514 . These values are accurate to 0.002° . Pasteurization for 20 min. at 60° raises the f. p. about 0.002. Sepd. milk added to whole milk does not affect the f. p., but, of course, H_2O raises it. The method may in some cases be applied to advantage in the detection of added H_2O and the approx. detn. of the amt. present, but is hardly suitable for general milk control work.

H. S. BAILEY.

The examination of adulterated milk. R. EICHLÖFF AND H. BLECKMANN. *Milch-wirtsch. Zentr.* 43, 561-9 (1914).—The authors conducted a series of comparative examns. of milk, skimmed milk, watered milk, and of milk that was both skimmed and watered, to det. the degree to which results obtained in such examns. are affected by the use of $\text{K}_2\text{Cr}_2\text{O}_7$ as a preservative. Their investigations also included a study of the relative merits of gravimetric analysis vs. application of the Fleischmann formula as methods for detg. total solids of milk. The detailed results obtained are given in 7 tables. E. and B. conclude, from their few expts., that the presence of 0.1% $\text{K}_2\text{Cr}_2\text{O}_7$ does affect the analytical results, whether detd. by gravimetric analysis or by application of the Fleischmann formula. The errors involved in the gravimetric method are slight but with the Fleischmann formula they may be so great as to lead to bad judgments regarding the degree of adulteration. For the detn. of total solids the authors recommend the use of the "Kosmos" balance (described) as a rapid and accurate method which requires no more time than the application of the Fleischmann formula. Teichert has compared the "Kosmos" balance with the gravimetric method and found that in 12 series of results the av. values obtained by the 2 methods varied only about 0.1%.

G. A. MENGE.

Analysis of milk. Determination of total solids and total nitrogen. G. MEILLÈRE. *J. pharm. chim.* 11, 167-70 (1915).—For total solids, evap. 5-10 cc. of milk in cylindrical dishes (7 cm. diameter, 2.5 cm. high) in a bacteriolog. oven at 37° for 3-4 days. For total N, evap. 10-20 cc. milk in Kjeldahl flask, add 10-15 cc. H_2SO_4 , 5-7 g. K_2SO_4 and proceed as usual. Clearing up will occur in at most 2 hrs. Before distn. with NaOH , the slightly acid liquid is boiled to expel CO_2 so as to obtain a final sharp end reaction with the indicator (alizarin red, hematoxylin or litmus). In distg. the alk. liquid a Delattre reflux tube should be used so as to have a minimum vol. of distillate. Additional precautions are mentioned.

S. WALDBOTT.

Milk fat determination with the alpha butyrometer kolibri. I. O. VON SOBBE. *Milchwirtsch. Zentr.* 44, 23-27 (1915).—Description of special form of apparatus. Results compared with those of Gerber method are about 0.2% high.

I. L. VAN SLYKE.

The effects of certain condensing and drying processes used in the preservation of milk upon its bacterial contents. S. DELEPINE. *Rept. to Local (Brit.) Gov. Bd., Food Rept. No. 21, 1-49(1914); J. Soc. Chem. Ind. 34, 297(1915).*—A study of 3 methods: (A) manuf. of sweetened condensed milk; (B) of dry milk by revolving heated cylinders, and (C) of dry milk made by spraying into a current of hot air. There were fewest bacteria in the milk made by (A) and most in (C). There was a point in each of the methods where the total bacteria were less than in the finished product, due to contamination during the final stages of the processes. The decrease was due largely to the destruction of *Streptococci*, *Staphylococci*, *Sarcinae*, *B. coli*, *Streptothrichae* and yeasts. In none of the methods was the heat sufficient to kill several saprophytic and some pathogenic bacteria. The milk was never found quite sterile. Apparently the most hardy were the spore-forming bacilli, *B. mesentericus*; some *Streptothrichae* may have survived, but the evidence is not conclusive. Living t. b. of bovine origin survive all treatments. The t. b. in the milks from methods (A) and (B) were still capable of producing tuberculosis in guinea pigs inoculated subcutaneously, but the disease was slower than when untreated t. b. milk was used, being latent for about 4 weeks. Young rabbits fed the (A) or (B) milk did not get tuberculosis. Bact. standards for "preserved" milks should be fixed with the knowledge, that with proper care, recontamination may be almost entirely prevented. The total number of aerobic bacilli should seldom exceed 100 per g.

H. S. BAILEY.

Sudden change in composition of a cow milk. O. ALLEMAN. *Milchwirtschaft. Zentr. 44, 122-3(1915).*—Milk which was abnormal in taste and comp. and which did not react with rennin changed its compn., becoming more nearly normal in two days; it was drawn 7 weeks after beginning of lactation period. In a second sample sp. gr. fat, lactose and casein increased, while ash albumin and lactoglobulin decreased. The later milk reacted with rennin. In the ash, the Ca, Mg, K and P_2O_5 increased in the second sample, while Na, Cl and S decreased.

L. L. VAN SLYKE.

Bacteriological control of feeding-stuffs in relation to the feeding of milk cows and production of hygienic milk. C. GORINI. *Milchwirtschaft. Zentr. 44, 129-33(1915).*—The microorganisms especially to be guarded against in milk production are the gas forming and putrefactive. These are commonly associated with impure water and partly spoiled feeds. As preventive measures, it is advised that (1) all fields on which crops are grown for cattle should be well drained, (2) hay should be well dried to prevent abnormal fermentation, and (3) careful preparation and preservation of siloed materials, using pure cultures and controlling temperature of fermentation in order to produce sweet silage or lactic acid silage.

L. L. VAN SLYKE.

Fat content of Swiss emmenthaler cheese. G. KOESTLER. *Milchwirtschaft. Zentr. 43, 517-24(1914).*—On the basis of many analyses, Swiss Emmenthaler cheese, when properly made, contains fat to the extent of at least 45% of its dry wt. The relation of the fat in the milk used to the fat in the cheese produced is so variable that the fat content of the milk cannot be used with sufficient accuracy for the purpose of calcg. the fat in the dry mass of the cheese.

L. L. VAN SLYKE.

Modification of Eichloff's flask for the determination of fat in cheese. C. BARTHEL. *Milchwirtschaft. Zentr. 43, 529-30(1914).*

L. L. VAN SLYKE.

Fat content in dry substance of the most important commercial kinds of Italian cheese. G. FASCETTI. *Milchwirtschaft. Zentr. 43, 538-40(1914).*—The discussion is limited to (1) Grana cheese with the two types "Reggiano" or "Emiliano," and "Lodigiano" or "Lombardo;" (2) Pecorino cheese and (3) Gorgonzola. The percentage of fat was found to vary widely. In Grana cheese, the fat should amount to at least 30% the dry substance; in Pecorinos cheese 40%; in Gorgonzola 45 or 50%.

L. L. VAN SLYKE.

Normal fat content of Danish varieties of cheese. ORLA JENSEN. *Milchwirtsch. Zentr.* 43, 540-42(1914).—The fat content of cheese is discussed when cheese is made from normal milk and from milk containing 50%, 25%, 15% and 10% of skim-milk.

L. L. VAN SLYKE.

Regulation of fat content of milk for cheese-making. G. WENGER. *Milchwirtsch. Zentr.* 44, 113-18(1915).—A method is given by which milk can be skimmed so as to reduce the amt. of fat to a uniform percentage for making cheese. Various formulas are given enabling one to calculate amt. of fat to be removed, when milk of a known percentage of fat is used, in order to reduce the percentage of fat to uniformity.

L. L. VAN SLYKE.

A rapid method for determining fat in cheese. TEICHERT. *Allgäuer Monatsschr. Milchw. u. Viehs.* 2, 13-4(1914).—A method by which the fat content of cheese may be detd. in 15 min. is described. A sample weighing 2.5 g. is dissolved in a porcelain dish with 8 cc. of H_2SO_4 (sp. gr. 1.6) and the resulting mixt. poured into a butyrometer graduated from 0 to 35. After rinsing the dish with 8 cc. more of H_2SO_4 , the washings and 5 cc. of amyl alc. are poured into the butyrometer which is then stoppered with rubber, centrifuged for 5 min. and placed in a water bath at 60° to 70° for 5 min. and the height of the fat column read. It is advisable to centrifuge for another 2 min. and read again, but this is not necessary.

WM. P. GARRETY.

The use of pure cultures in cheese-making. C. GORINI. *Milchwirtsch. Zentr.* 44, 118-22(1915).—The paper is a general discussion of the subject which was given at the Intern. Dairy Congress in Bern in June, 1914.

L. L. VAN SLYKE.

Use of lactic acid bacteria in cheese-making. O. GRATZ. *Milchwirtsch. Zentr.* 44, 134-36(1915).—This is an address made at the Intern. Dairy Congress at Bern in 1914, and is a statement of general facts.

L. L. VAN SLYKE.

The examination of dairy salt. A. WOLFF. *Milchwirtsch. Zentr.* 43, 545-51(1914).—W. advocates that salt which is incorporated into manufactured dairy products be carefully examd. for bacteria as well as for other impurities. A bacteriological investigation of samples of salt used in butter making and in cheese making disclosed the presence of considerable numbers of nonpathogenic bacteria as well as molds and yeast. The salt used in cheese was found to be more contaminated than that used in butter. In one case the brine made from such salt contained 315,000 bacteria per cc., including lactic acid bacteria, colon bacilli, putrefying bacteria, various cocci, spore-formers, molds, yeast, and other forms. W. claims that certain of the bacteria found will decompose butter fat and that therefore their presence in butter, due to the addition of even a little contaminated salt, will cause its steady deterioration. The samples of salt studied were obtained and examined under different conditions and the indicated bacterial content varied accordingly.

G. A. MENGE.

Detection of nitrates (TINGLE) 7. Germicidal value of lactic acid in milk (HEINEMANN) 11C. Drying beet chips (ROSE) 28.

Brit., 3,824, Feb. 13, 1914. E. SHAW. Sweetmeats such as hard boiled goods are made by adding to the sugar a soln. of sugar which has been inverted by means of an acid and neutralized, $NaHSO_3$ being afterwards added. Sugar is dissolved in H_2O and brought to boiling. This soln. is then inverted by the addition of HCl after cooling to such temp. that the acid does not cause discoloration. Na_2CO_3 is added to neutralize the acid. The soln. is then mixed with sugar in the proportion of about 5 gals. of soln. to 2 cwt. of sugar, which is brought to boiling and about 5 oz. of $NaHSO_3$ added. The batch is boiled by passing it through a machine of the type described in 20,766, 1908 (cf. C. A. 6, 1869).

Brit., 3,867, Feb. 14, 1914. J. ANFOSSI. In a process of preserving fruit, tangerines or other fruit are maintained at 60-70° in a sirup of sugar and glucose at about 10° Bé. in open earthenware pans. Sirup is added from time to time, and is coned. to about 33° Bé. The tangerines are finally drained, washed with hot H₂O, and glazed in pure sugar sirup. Before treatment, the tangerines are lightly skinned, and boiled in H₂O. The earthenware pans are heated by a flue from a coal or gas fire. The temp. is controlled by a register and vents, and metal sheets may be placed beneath any pans receiving too much heat. The fire may be replaced by a steam heater.

Brit., 4,589, Feb. 23, 1914. E. SAMUELSON and J. BACKHOUSE. A heater for grain or the like. Cf. C. A. 9, 339.

Brit., 4,649, Feb. 23, 1914. R. NORTON, H. SIMON, LTD., E. SAMUELSON and J. BACKHOUSE. In conditioning grain, the container in which the grain is subjected to steam or air has a perforated bottom coating with a movable perforated plate to control the outflow.

Can., 160,831, Feb. 23, 1915. C. H. CAMPBELL. The method of treating liquid as in the pasteurization of milk, by rapidly raising the temp. uniformly throughout the entire mass of liquid under treatment, and then rapidly lowering the temperature uniformly throughout the said entire mass.

Ger., 278,942, Oct. 18, 1913. S. MAYER, SR. App. for the automatic and individual charging of vinegar vats.

Ital., 118,304, 391,242, Jan. 11, 1913. VON GISEWALD CONWAY. Mfg. edible gelatin by treating the raw material by high pressure steam for a short time, reducing the pressure but leaving the boiler full of steam, closing and allowing to cool, thereby producing a vacuum.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Interpretation of chemical water analysis. R. DROSTE. *Chem. Ztg.* 39, 54 (1915); *Chem. Zentr.* 1915, I, 457.—A thorough local survey, including the geological features is necessary in addition to the analytical results. ARTHUR LEDERER.

Titration of chlorine ions in water. O. MAYER. *Z. anal. Chem.* 54, 147-58 (1915).—The Cl results obtained by Mohr's method are too high. Tillmans and Heuble (cf. C. A. 7, 4025) recommended the addition of 1 cc. of a 10% K₂CrO₄ soln. to each 100 cc. of water. M. shows exptly. that errors due to the solubility of Ag₂CrO₄ are practically negligible. The titration should be carried on in the cold. Mohr's method is convenient, but if accurate results are required the grav. method should be resorted to. ARTHUR LEDERER.

Comparison of methods for the determination of oxygen in waters in the presence of nitrites. ELIAS ELVOVE. *U. S. Hyg. Lab. Bull.* No. 96, 15-35 (1914).—Levy's method is not reliable in the presence of nitrites. In the presence of considerable nitrite the results by the Hale and Melia K acetate modification of Winkler's method may be too high if there is not a sufficiently long period intervening between the addition of K acetate and the titration of the I. At 20° with a water containing 5 p. p. m. of nitrite the proper interval is 15 min. The permanganate modification of Winkler's method is most reliable, as it also takes into account the organic matter.

ARTHUR LEDERER.

The determination of the quality of drinking water. ELMANOWITSCH AND J. ZALESKI. *Z. Hyg.* 78, 461-74 (1914).—The quality of drinking H₂O and the nature of

its contaminating substance can be ascertained by detg. the degree of absorption of O and Cl.

JULIAN H. LEWIS.

The colloidal clay treatment for trade wastes. P. ROHLAND. *Zentr. Gewerbehygiene* 2, 141-5(1914); *Wasser u. Abwasser* 9, 38(1914); cf. *C. A.* 9, 944, 1210.—R. recommends clay treatment for wastes containing much organic matter. It is not suited for the purification of the inorganic potash waste liquors.

ARTHUR LEDERER.

A comparative study of settling in Emscher, Kremer, Stieg, and Neustadt tanks, biologic treatment, and chemical precipitation, made at Stuttgart. EMIL MAIER. *Gesundh. Ing.* 37, 769-79, 805-11, 857-60(1914).—Purely mechanical purification shows the greatest efficiency at the lowest cost. Approx. $\frac{1}{2}$ of the organic substances are removed from the sewage. The cost of clarification is approx. 0.7 pfennig per cu. m. of sewage. The chem. or biologic purification is much more difficult to accomplish and more expensive. The costs of chem. and biologic treatment are 3 and 2.5 pfennig per cu. m. resp. and, while the biologically treated sewage is completely stable, the chemically treated is not.

ARTHUR LEDERER.

Purification of domestic sewage in fish ponds. HOFER. *Wasser u. Wegebau Z.* 1914, No. 5, 54-5; *Wasser u. Abwasser* 9, 38(1914).—Sewage should be diluted with an equal volume of fresh water previous to its discharge into a pond. The depth of ponds should not exceed 0.5 m. so that sunlight can penetrate to the bottom. Detrimental overgrowths by water plants can be prevented by keeping ducks. H. estimates a required area of 1000 sq. m. for each 2000 inhabitants.

A. I.

Sewage disposal in sanitariums and hospitals. HUGO KÜHL. *Die Heilanstalt* 8, 193-6(1913); *Wasser u. Abwasser* 9, 37(1914).—Irrigation in various forms is the best system. If suitable land is not available, biologic treatment should be resorted to. A number of plants for German institutions are briefly discussed.

A. I.

The colloidal clay treatment of slaughtering house waste. P. ROHLAND. *Deutsche Tierärztl. Wochenschr.* 21, 560-1(1914); *Wasser u. Abwasser* 9, 38(1914).—R. recommends this method of treatment particularly for the purification of slaughtering house waste. Cf. *C. A.* 9, 944, 1210.

ARTHUR LEDERER.

Slaughtering houses. A. STEIN. *Gesund. Ing.* 38, 217-20(1915).—Discussion of technical details of a sanitary slaughtering house.

ARTHUR LEDERER.

Apparatus for fumigation with cresyl. HARALD SEIDELIN. *Yellow fever Bulletin* No. 3; *Rev. int. Hyg. publ.; Schweiz. Apoth. Ztg.* 53, 227-8(1915).—Bouet and Roubaud obtained efficient results with 5 g. cresyl per cu. m., heating it in open, deep vessels to diminish danger of ignition. S. uses glass retorts whose stems pass through holes in the door of the room to be treated. Heating is done by petroleum or alc. Metal retorts might be used if a blast lamp is available.

S. WALDBOTT.

Gas fires and ventilation (SMITHS) 21.

Brit., 4,018, Oct. 24, 1914. R. P. VAN CALCAR and H. J. MARTIJN. In a process of drying and sterilizing air by solid desiccants and the soln. derived from their liquefaction, the air is led into the app. in a number of converging streams under strong suction, and flows through in a sinuous path over or past a number of downwardly directed baffles, down which the liquefied desiccant streams from the troughs.

Brit., 4,020, Oct. 24, 1914. R. P. VAN CALCAR, J. ELLERMAN and H. J. MARTIJN. In a process and app. for drying and sterilizing air as described in 4,018, 1914 (*supra*), a preliminary removal of moisture is effected in the lower part of the app. by the passage of the air over porous baffles which absorb the liquefied desiccant flowing into

the trough from the baffles on the bottoms of the perforated trays of desiccant. The baffles may be solid or hollow, and straight, spiral, or otherwise shaped.

Brit., 4,564, Feb. 21, 1914. C. T. KINGZETT, E. P. KINGZETT and SANITAS CO. An app. for generating gaseous formaldehyde for disinfecting consists of a vessel having fixed or cast therein a block formed of KMnO_4 and plaster, etc. The vessel received a second vessel containing HCHO soln., which is poured over the block when the gas is to be generated.

Fr., 467,687, Jan. 24, 1914. DEUTSCHE FILTERKOMPAGNIE, G. M. B. H. Natural stone, after suitable wet treatment, is prepd. for use in the purification of water by treatment with acids (HCl), whereby the injurious bases are removed, and the mass is converted into a porous condition, whereupon it is enriched with NaCl and, in certain circumstances, with Mn salts.

Fr., 468,864, Feb. 24, 1914. E. W. JANSON. Treating waste water slime by adding naphtha (0.5-4%) to the compressed slime cake, and subjecting it to dry distn., with exclusion of air, at $260-480^\circ$. The fatty acids protected from decompn. by the naphtha vapors (Ca stearate, palmitate and oleate) go over in part with NH_3 . The retort residue is heated to $540-650^\circ$ and the mass, consisting of lime, SiO_2 , animal charcoal, H_3PO_4 , etc., is used for the pptn. of further quantities of waste waters.

Ger., 281,580, May 25, 1913. M. KUSCH. Constructional details of a clarifying apparatus.

Ger., 281,810, June 7, 1913. SUCROFILTER- UND WASSERREINIGUNGS-GES. M. B. H. Obtaining sterile potable water from any impure H_2O by adding KMnO_4 and CuSO_4 in amts. sufficient to kill the microorganisms, and then, after the addition of H_2O_2 in amt. sufficient to convert the salts into insol. form, filtering the H_2O . The specified salts are applied in tablet form, and allowed to act on the H_2O for 10 mins. The effectiveness of the process resides in the fact that the CuSO_4 , besides having bactericidal properties, acts as a catalyzer by stimulating the liberation of the O from the KMnO_4 (which constitutes its bactericidal power) to such an extent that the organisms in suspension are killed in a short time. By the addition of H_2O_2 after 10 mins., the KMnO_4 is pptd. as MnO_2 and the CuSO_4 as CuO . Upon filtration the CuO goes into the slime and kills all the spores in the slime, thereby preventing growth through the filter and ensuring continued freedom of the filtrate from pathogenic organisms. E. g., impure H_2O 4 liters are mixed with 3 g. CuSO_4 and 3 g. KMnO_4 and after 10 mins. 4 g. H_2O_2 (0.36%) are added and allowed to act for 3 mins. and the mixt. is filtered.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Acids and colloids of humus. GUSTAV FISCHER. Halle. *Kühn-Archiv*. 4, 1-136(1914); *Biedermanns Zentr.* 43, 660-5(1914).—Investigations are reported relative

to purification methods, especially dialysis, colloids of composts and soils, ultrafiltration, reversibility and irreversibility of colloids, H-ion concn. measurement by means of e. m. f., hydrolysis, acid reactions of materials, migratory tendency and speed both with and without acid and alkali additions, elec. potential of colloid particles, coagulation, humus colloids in presence of colloid gold, etc., precipitation limits, effects of electrolytes, comp. of inorganic constituents, microscopic and ultramicroscopic exam., fluorescence and relation of humus colloids to certain organic color-materials. The results do not lend themselves to brief abstracting.

W. H. FRY.

The biochemical reduction processes in the soil. C. A. H. VON WOLZOGEN KÜHR. *Arch. Suikerind.* 23, 501-11 (1915).—K. discusses mainly the action $2C + CaSO_4 + H_2O = CaCO_3 + H_2S$ as caused by *Microspira desulfuricans*. C — represents the organic material which serves as a source of C. In many tropical soils the black color is due to FeS from the above reaction, rather than to organic material. The detn. of the reducing power of a soil is based on its power to reduce ferric salts. Boil 50 g. of the soil for 3 min. with 200 cc. of 10% H_2SO_4 , filter, cool, and titrate with $KMnO_4$. This gives the total reducing power. To det. the ferrous salts present (as distinguished from organic material of reducing power) ext. with cold 10% AcOH and titrate with $KMnO_4$. In cane fields which show local spots of poor growth, soil samples from these spots will often show a greater reducing power than samples from localities of normal growth.

W. L. BADGER.

Isolation of *Bacillus radicola* from soil. CHAS. B. LIPMAN. *Science* 41, 725 (1915).—Correction of errors as to date and credit for priority.

W. H. FRY.

Sulfur and permanent soil fertility in Iowa. P. E. BROWN AND E. H. KELLOGG. *J. Am. Soc. Agron.* 7, 97-108 (1915).—"Iowa soils are shown to contain small amts. of total S, much less on the average than the P content in the case of each of the large soil areas. Some of the S removed from the soil by crops may be returned by the use of manure." Such amts. would be insufficient to keep up the S content of soils, and, in certain contingencies, the employment of S-bearing fertilizers may become necessary. Acid phosphate seems the logical fertilizer to use, as it supplies both S and P.

B. E. B.

The question of the dissolving action of roots. TH. W. CHIRIKOV. *Russ. J. exp. Landw.* 1914, 64; *Biedermanns Zentr.* 44, 66-7.—From expts. on barley and buckwheat with phosphorite and $Ca_3(PO_4)_2$, it is concluded that the theory of root secretion of acids does not explain a whole series of facts concerning the nutrition of the higher green plants. The plant roots are surrounded by a soln. in a certain equil.; the comp. of this soln. depends not on the quantity of the solid phase but only on the comp. of the fluid phase. Roots of different plants disturb this equil. very unequally; one absorbs chiefly CaO, another P_2O_5 . Barley does not take up P_2O_5 of phosphorite in the presence of $Ca(NO_3)_2$ or other Ca salt, but with phosphorite alone it takes up its P_2O_5 to a considerable degree. Buckwheat takes up P_2O_5 of phosphorite as well in the presence as in the absence of $Ca(NO_3)_2$. This difference can be explained on the ground that buckwheat energetically withdraws CaO from the nutrient soln. and thereby facilitates the passage of P_2O_5 into the soln., whereas with barley P_2O_5 is taken up much more energetically than CaO.

W. H. FRY.

Calcium cyanamide as a retarder of denitrification. CORRADO LUMIA. *Atti accad. Lincei* 23, II, 659-62 (1914).—Expts. showed that an addition of 0.15% Ca cyanamide to a nutrient soln. decreases the denitrification. Its advantages over $(NH_4)_2SO_4$ and $NaNO_3$ as a fertilizer are due to this fact. The best utilization of inorganic fertilizers was obtained by mixing them with Ca cyanamide.

E. J. WITZEMANN.

The inter-relationships between the constituents of basic slag. S. H. COLLINS AND A. A. HALL. *J. Soc. Chem. Ind.* 34, 526-30(1915).—The results of analysis exhibit certain relationships, the most interesting being those occurring between the citric solubility and the general compn. The coeff. of correlation is detd. from the formula: $r = \Sigma xy / \sqrt{\Sigma x^2 \Sigma y^2}$ where x is the departure from the mean of the citric solubility and y is the departure from the mean of the fineness or other property supposed to be correlated. When correlation is perfect the formula works out to be equal to unity, and when there is no correlation the result = 0, and when the quantities move in opposite directions the result has a minus sign. The probable error of the coeff. is calcd. from the formula $\mu = 0.674 (1 - r^2) / \sqrt{n}$ in which r is the coeff. and n is the number of pairs which are correlated. The correlation between the citric solubility and the CaO is very striking and shows that (in the case of a slag) a high CaO content and a high citric solubility are very intimately connected, the high CaO content having a greater influence than fineness. The evil influence of SiO_2 is striking. MgO appears to hinder the soln. of a slag in citric acid. Mn, Fe, and V have no important influence on the citric solubility. Tables and curves are given showing the correlation among the constituents, between the hay crop and the constituents of the basic slag over a 10 year period, the balance between the constituents of slags. Conclusion: "It is quite well known that such substances as MgO and Mn influence the cropping power of a soil and that these constituents vary considerably in slag. The most important constituent of slag is P_2O_5 , but no general investigation has been attempted to discover the constituents of secondary importance. The wide attempt made here to find out the most likely ingredient to rank in the second place of importance, shows that even if these be all taken into account something more will be needed to give a fair presentation of the facts of the case. Not merely do many other constituents appear to have value, but there seems much reason for supposing that a balance of the secondary constituents is needed. Medium proportions of MgO, Mn, and Fe are all useful, but extra large proportions harmful. The citric solubility of slags is correlated with the constituents of slags in such a manner that it may form a useful test, provided that its arbitrary and conventional character is recognized."

F. W. SMITHER.

Is the Lorenz-Neubauer method for the determination of citric acid-soluble phosphoric acid in Thomas meals applicable? H. DUBBERS AND CELICHOWSKI. *Landw. Jahrb.* 47, 71-8(1914).—The contentions of Lemmermann and Haussding (cf. *C. A.* 8, 2591) are opposed. The Lorenz method is uncertain and therefore inapplicable. Both the Fe citrate method proposed by Popp and the method of Darmstadt give a very satisfactory degree of certainty.

C. F. MILLER.

The determination of phosphoric acid in vegetable material, namely in crops, and in phosphates. A. STUTZER AND W. HAUPT. *J. Landw.* 63, 46-9(1915).—Details are given for the ignition of the yellow molybdate ppt. in the detn. of P_2O_5 . No new principle is involved.

L. J. GILLESPIE.

Fermented molasses as a source of nitrogen and potash fertilizers in Italy. A. VITA. *Italia agricola* Feb., 1915; *Deut. Zuckerind.* 40, 350(1915).—In connection with a consideration of the lack of artificial fertilizers as a result of the war, V. recommends that fermented molasses and the residue from BaO treatment be used as a source of N and K. V. discusses the treatment of molasses residues in Italy by calcination in so-called "Porion" ovens for the recovery of K_2CO_3 , K_2SO_4 , KCl and Na_2CO_3 (with simultaneous loss of N) and the processes of Stolzenberg (rapid heating of 3 parts perphosphate with 2.5 parts thick molasses in order to fix N), Vasseau (treatment of the molasses with a calcd. amt. of H_2SO_4 sufficient to convert all K compds., etc. into sulfates, centrifuging the K_2SO_4 and treatment of the residue with perphosphate so as to obtain a fertilizer with a high content of N and P_2O_5) and Effront (decompn. of the amino

acids of the molasses with production of NH_3 by means of cultures of butyric acid bacteria which have become habituated to large amts. of NH_3 and distn. of this NH_3 with absorption in H_2SO_4 for the recovery of N from molasses residues. The use as fertilizer of the alk. (formerly exported from Italy) obtained from molasses presents difficulties because of the caustic action of the carbonates. Transformation of the latter into sulfates is not complete and is, furthermore, accompanied by increased expense due to the cost of H_2SO_4 . H. S. PAINE.

Toxic effect of iron and aluminum salts on clover seedlings. R. W. RUPRECHT. Mass. Agr. Expt. Sta., *Bull.* 161, 125-29(1915).—Fe and Al sulfates are shown to be quite harmful to the roots of clover plants. CaCO_3 and Ca(OH)_2 neutralize the injurious properties of the salts of Fe and Al in dil. solns. B. E. B.

The effect on a crop of clover of liming the soil. F. W. MORSE. Mass. Agr. Expt. Sta., *Bull.* 161, 119-124(1915).—Liming a soil increased the size of clover plants and the % of N in them when the clover was grown on soils without an application of N or when supplied with $(\text{NH}_4)_2\text{SO}_4$. The increase in the assimilation of N was apparently promoted by the action of the lime on the properties of the soil and not by its action within the plants. B. E. B.

Fertilizing sugar beets without Chile saltpeter. K. STÖRMER. *Blätter f. Zucker-rübenbau* 1914, 320; through *Wochschr. Zentr. Rübenzuckerind.* 52, 882(1914).—Prescriptions for the use of $(\text{NH}_4)_2\text{SO}_4$, $\text{Ca(NO}_3)_2$, or CaCN_2 , with phosphates and K; and with Na added as kainite to replace the Na of NaNO_3 . W. L. BADGER.

Fertilizing sugar beets with "cattle salt" (denatured common salt). A. STUTZER. *Deut. landw. Presse* 1914, 1007; *Wochschr. Zentr. Rübenzuckerind.* 52, 882(1914).— NaNO_3 may be replaced by $(\text{NH}_4)_2\text{SO}_4$ if at the same time a corresponding amt. of Na is added. This may be most cheaply obtained by using denatured NaCl , or from kainite. In the latter case K is also obtained. W. L. BADGER.

The action of common salt used with ammonium sulfate (in beet fertilizers). SCHNEIDEWIND, D. MEYER AND F. MÜNTER. *Landwirtsch. Wochschr. Provinz Sachsen* 1915, 3; through *Wochschr. Zentr. Rübenzuckerind.* 53, 68(1915).—Expts. were carried out with 40% K salts, with 40% K salts and NaCl , and with kainite (50% NaCl), all with both $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 . Both fodder and sugar beets gave as good results with kainite as with the mixed salts, irrespective of whether $(\text{NH}_4)_2\text{SO}_4$ or NaNO_3 was used. With fodder beets the dry substance was decreased but the yield per ha. increased; with sugar beets, neither dry substances or yield was effected. W. L. BADGER.

Experiments on the combating of stinking smut in winter wheat by means of the formaldehyde treatment. H. MÜLLER AND E. MOLZ. *Fühlings Landw. Z.* 63, 742-52(1914); *Chem. Zentr.* 1915, I, 799-800; cf. *C. A.* 9, 1363.—Results are given in considerable detail of seed treatments for the protection of wheat against smut. The investigators found that the soln. used in the steeping process (seeds immersed for 15 min. in a 1/4% soln. of the 40% formalin) can be used over and over without losing its efficacy if only a few hours elapse between the first and last treatments. The wetting process (wetting of seeds with 2-3 liters of the soln. per 100 lbs., mixing and drying) proved less satisfactory than the former. The superiority of HCHO over CuSO_4 as a steeping soln. is due especially to its slight injury to the viability of the seeds. The weakness of the method lies in the susceptibility of the seeds to reinfection. Paraformaldehyde proved altogether unsuitable. C. F. MILLER.

The toxicity of insecticides (WOODWORTH) 11D. Direct assimilation of atmospheric nitrogen by plants (MAMELI) 11D.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Absorption of sulfurous acid by wine. T. OMEIS. Würzburg. *Arb. kais. Gesundheits.* 49, 495-501(1914).—O. gives results of additional expts. to his earlier investigation. Cf. C. A. 8, 547. L. W. HAAS.

Spontaneous acid retrogression in wine. T. OMEIS. Würzburg. *Arb. kais. Gesundheits.* 49, 488-94(1914).—O. investigated the influence of (1) temp. of storage, (2) stirring up of yeast after principal fermentation, and (3) removal of yeast soon after completed fermentation. The expts. carried out with specimens of a poor vintage, confirm O.'s earlier observation. Cf. C. A. 8, 547. L. W. HAAS.

Refinement of beer. R. WAHL. *Am. Brewers Rev.* 29, 216-8(1915).—The efforts to increase stability and chill-proof quality of beer by the modification of the undesirable proteins in the finishing cask (by application of the peptic strength of malt activated by bacterial lactic acid) are reviewed. L. W. HAAS.

Importance of lactic acid in production of malt and beer. R. WAHL. *Am. Brewers Rev.* 29, 224-6(1915).—A review (cf. preceding abst.). L. W. HAAS.

Enzymes in malt that produce polypeptides and amino acids. LUDWIG ADLER. Weihenstephan. *Z. ges. Brau.* 38, 129-31, 137-42, 146-9, 153-5(1915).—In the expts. the polypeptide and the amino acid N were detd. by means of Sørensen's formol titration (cf. C. A. 8, 2025). From the exptl. data A. draws the following conclusions: The optimum temp. for both the polypeptide (or peptic) and the amino acid (or tryptic) producing enzymes in malt lies at 46°. Even after a duration of mashing of 24 hrs. under sterile conditions, the enzymic activity has not completely ceased; most work is accomplished during the first 8 hrs., possibly because until that moment by the action of a phosphatase (most probably phytase) the inorganic P_2O_5 and simultaneously the acidity increases. The largest quantity of formol-titratable N is produced in mashes with a H^+ conc. characterized by $pH = 4.3$ to 5.0 . This optimum H^+ conc. is not reached by spontaneous acidification until 12 hrs. after the start of mashing at 46°. Both enzymes are more sensible to H^+ than to OH^- , and by the latter the peptic enzyme is much more easily destroyed than the tryptic. The formation of amino acids seems to be due principally to an endoenzyme, while the secretion enzymes produce polypeptides and amino acids at equal rates. The proteolytic enzymes in malt also act upon foreign proteins (those tried were Witte peptone, edestin and gelatin), preferring proteins peculiar to malt, and barley, respectively. L. W. HAAS.

Use of sugar (sucrose) as additional mashing material. F. KORITSCHNER. *Brau. Malsind.* 16, 108-15(1915).—The appearance of fermentation of pure malt wort differs in no way from that of worts in the preparation of which varying proportions of malt are replaced by beet sugar, and in no case was it possible to draw conclusions from the course of fermentation as to an addition of sugar. Of greatest importance is the regulation of the degree of final fermentation, which, as is shown, may easily be effected by joint employment of black or caramel malt. L. W. HAAS.

Preservation of wort. F. SCHÖNFELD. *Wochschr. Brau.* 31, 354(1914).—It may be economical (for small breweries to meet the fluctuating demand for beer of quick consumption) to make large brews and to preserve the wort in a sterile condition for fermentation as and when required. Suitable storage is provided by cylindrical metal tanks (after the pattern of those used for the cultivation of pure yeast by the Stockhausen-Coblitz method), holding 1 to 10 hl. of wort. These are filled with the hot wort and closed with a cover having a rubber washer and held down by a weak spring; as the wort cools the cover is drawn down and closes the tank gas-tight. To

prevent the collapse of the tank under the partial vacuum, the bottom, which is constructed of relatively thin metal, is made convex and is drawn inwards as the contents of the tank contract.

L. W. HAAS.

Acceleration of fermentation (by dead yeast). E. MOUFANG. *Allgem. Brau.-Hopfen-Ztg.* 55, 605-7(1915).—It is shown that dead or killed brewer's and baker's yeast have a strong catalytic action on fermentation. M. concludes that this fact cannot be attributed solely to the nutritive value of dead yeast, but must be due to an increased enzymic activity of the living cells caused by the partial assimilation of the dead yeast.

L. W. HAAS.

Some technical phases of alcoholic fermentation. V. WM. L. OWEN. *Sugar* 17, 45-47(1915).—The influence of the shape and size of fermentation vats upon fermentation efficiency is discussed.

A. GROSS.

Results obtained by the application of the "Molhant" process of fermentation to cane molasses. V. MIROIR. *Bull. assoc. chim. suc. dist.* 31, 936-40(1914).—In the ordinary method of fermentation the molasses is dild. to 6° Bé., acidified with 1 g. H₂SO₄ per l. and various yeasts added. A "must" containing 4-4.5% alc. is obtained. In the "Molhant" process the fermentation is carried on in 3 stages. To the yeast is added a small amt. of molasses dild. to 6° Bé. and acidified with 3.5 cc. HCl per l. and the whole is allowed to become well fermented. This is then pumped to a larger tank and more molasses of the same diln. and acidity is added. This is also allowed to ferment for 24 hrs. and is then pumped to the largest tank where plain molasses of 14° Bé. is added until the whole mixt. is about 12° Bé. Fermentation is completed in 24-30 hrs. and a "must" containing 9-9.5% alc. is obtained. This more concd. soln. reduces the time and expense of distg. In the "Molhant" process there is formed 60.23 l. alc. per 100 kg. of sugar calcd. as sucrose. This is 1.5 l. per 100 kg. more than is obtained by the old process.

Ger., 279,991, Jan. 21, 1913. STANDARD ALCOHOL CO. Production of fermentable sugar from initial materials containing cellulose. Cf. C. A. 6, 3340; 8, 3215.

Ger., 281,558, Jan. 9, 1913. NATHAN-INSTITUT, A.-G. In the manuf. of beer, the air is expelled from the wort before the beginning of the fermentation by means of CO₂ formed in the process and this is then freed from the O of the air. In the fermentation the yeast remains in the lower part of the vat, the CO₂ as generated carries the air with it as it passes through the supernatant liquid, and the yeast then rises. To remove the O of the air the CO₂-air mixt. is conducted over incandescent Cu turnings, or, together with H, over incandescent contact substances (Pt sponge or Pd asbestos).

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Peroxide of hydrogen. A. MCGILL. Lab. Inland Rev. Dept., Ottawa, Canada, *Bull.* 306, 6 pp. (1915).—A report on the examn. of 37 samples of H_2O_2 on the Canadian market.

E. J. C.

A simple quantitative determination of gum in tragacanth. OTTO FREY. *Apoth. Ztg.* 30, 63-4 (1915).—The paper deals with criticisms made by Fromme (cf. *C. A.* 8, 3094) of the author's method and tends to show that the former's inability to obtain satisfactory results therewith were mainly due to the fact that too little solvent was used in the operation, and that other modifications employed or suggested by Fromme are unnecessary and undesirable. Additional analytical data are offered substantiating these views.

W. O. E.

Evaluation of organic silver preparations. F. LEHMANN. Univ. Koenigsberg *Arch. Pharm.* 253, 42-6 (1915).—After discussing the methods of Kroeber, Stoecker, Danckworrt and Warnecke for detg. Ag in organic Ag preps., the following procedure is suggested: Dissolve 0.2-1.0 g. sample (depending on the nature of the prep. under examn.) in 10 cc. H_2O contained in a 400 cc. Erlenmeyer, add with const. agitation 10 cc. conc. H_2SO_4 and follow with 2 g. finely powd. $KMnO_4$ (4-5 g. for preps. containing considerable Cl), adding the reagent in small portions and then allowing to stand 15 min. In the case of Cl-free preps., dil. the mixt. with 50 cc. H_2O , decompose the excess of manganic compds. by the addition of $FeSO_4$ in small portions until a clear yellowish soln. results and then titrate with 0.1 *N* NH_4CNS . In the case of products containing more or less chlorides, heat the mixt. on the wire gauze in order to decompose the $AgCl$ and until the condensing vapors of H_2SO_4 have washed down all traces of Mn compds. adhering to sides of flask. After cooling, dil. with 50 cc. H_2O and titrate as above. One cc. 0.1 *N* NH_4CNS soln. = 0.0108 g. Ag.

W. O. E.

Behavior of iodized starch toward the Pukall cell and Vanino's reagent. L. VANINO AND A. SCHINNER. *Arch. Pharm.* 253, 47-51 (1915).—Expts. made to det. to what degree, if at all, starch and iodized starch solns. partake of a colloidal character developed the fact that ordinary starch soln. (that of glycogen and inulin as well) is taken up by the Pukall cell, while iodized starch soln. does not permeate the cell at all. All iodized starch solns. are pptd. by Vanino's reagent, the iodized soln., however, with difficulty and then incompletely. In certain cases, this reagent not only equals but even surpasses the Pukall cell in sharpness and delicacy. Thus, it was shown that aq. solns. of Brazil wood, redwood, fustic logwood, Berlin blue and litmus are all taken up by the Pukall cell, while with the $BaSO_4$ reagent a litmus soln. of 1:300 and one of sol. Berlin blue of even higher diln. were completely pptd. after 1 shaking. Aq. I soln. is almost completely decolorized after 14 days shaking with Vanino's reagent, but is unaffected by the Pukall cell, although solns. of I in alc., $CHCl_3$, CCl_4 and CS_2 are immediately absorbed by this cell; they are not pptd. by the $BaSO_4$ reagent.

W. O. E.

Investigation of quinine sulfate. Z. P. POLAK. *Pharm. Weekblad* 52, 579-604 (1915).—The NH_4 -test has 2 chief disadvantages: (1) a much too small amt. of the other alkaloids is brought into the soln. to be analyzed, and (2) a method in which so small a portion is obtained brings about irregular results. In the prepn. of a metastable soln. which is the essential point in the Kerner-Weller test, there are too many factors which cannot be controlled. Although this is perhaps the best method known for the detn. of the purity of com. quinine, P. believes that some other method, free from so many errors, should be substituted for it, even if this is not more sensitive than the old method.

P. V. D. MEULEN.

Colombian tolubalsam. P. VAN DER WIELEN. *Pharm. Weekblad* 52, 631-4 (1915).—A sample of tolubalsam of good quality, imported directly from Colombia, gave on investigation in accordance with the methods of the German Pharm. an acid no. of 120.4, a sapon. no. of 226.8 and an ester no. of 106.4. This is higher than the ester no. of any sample of Tolubalsam previously investigated. The author suggests that the upper limit of the ester no. be raised, or else be omitted entirely, as is done by the French Pharm. P. v. D. MEULEN.

The preparation of malt extract containing vitamine. P. VAN DER WIELEN. *Pharm. Weekblad* 52, 673-4 (1915).—The prepn. from potatoes is carried out as follows: 2 kg. of potatoes are carefully cleaned or thinly pared and cut up into large pieces of uniform size. They are covered with water, boiled until they fall apart, and passed through a horsehair sieve by rubbing. The material passed through the sieve is boiled $\frac{1}{2}$ hr., cooled to 60°, mixed with $\frac{1}{4}$ kg. of finely ground barley malt, and allowed to stand at 60° until the liquid gives no test for starch. It is then filtered at once and evapd. immediately to the dry ext., preferably *in vacuo*. The yield from 1 kg. of potatoes and $\frac{1}{4}$ kg. of barley malt is about 430 g., of which 140 g. comes from the barley malt and 290 g. from the potatoes. The yield is frequently lower. P. v. D. MEULEN.

Further investigations on the content of free and combined nicotine in Hungarian Cserbl tobacco. JULIUS TORH. *Chem. Ztg.* 39, 349 (1915); cf. C. A. 8, 985.

J. H. MOORE.

The drug situation in 1914. ANON. *Chem. Ztg.* 39, 397-8, 406-7 (1915).

J. H. MOORE.

Rapid method for the determination of alcohol in alcoholic solutions containing essential oils (perfumes, etc.). MARINO ZUCO. *Ann. lab. chim. centrale Gabelle* 6; *Giorn. farm. chim.* 62, 120 (1913).—The essential oils may be eliminated by dilg. the alc. soln. to approx. 3 times its vol. with a 5% soln. of alum, cooling to 15° and filtering. One-half of the filtrate (which is quite clear) is taken and distd.; the % of alc. is then detd. as usual from the d. of the distillate by reference to the original vol. H. S. P.

Medicinal wines. ANON. *Boll. chim. farm.* 52, 6 (1913).—When a medicinal wine is desired it is advisable to use a wine which is free from tannin, inasmuch as the latter ppts. certain of the active principles of plants as tannates. The use of an artificial wine composed of cognac, H₂O and honey is suggested. H. S. PAINÉ.

Fluid extract for iodotannic sirup. ANON. *Boll. chim. farm.* 52, 504 (1913).—This fluid ext. is prepd. from 4 pts. tannic acid, 76 pts. simple sirup and 20 pts. tincture of I. The tannic acid is dissolved in the sirup and the tincture of I is then added. The mixt. is heated in a flask on a H₂O bath under a reflux condenser until it no longer gives a blue coloration with starch paste. The iodotannic sirup is prepd. from 100 pts. fluid ext. and 900 pts. simple sirup. H. S. PAINÉ.

New reaction of guaiacol. PARIDE TORTI. Como. *Boll. chim. farm.* 53, 299 (1914).—A crystal of guaiacol assumes an intense red coloration when treated with a drop of HNO₃ (d. = 1.40). The colored substance thus obtained is sol. in H₂O, alc., CHCl₃, and Et₂O. Minute, dark, glittering crystals are obtained by spontaneous evapn. of the Et₂O soln. in the air. An aq. soln. of guaiacol, when treated with HNO₃ (d. = 1.40), assumes a red coloration which is transitory and gradually changes to orange and yellow, the original color becoming more transitory as the conc. of the soln. decreases; the change of the original coloration to orange and yellow is facilitated by heat. This coloration is still perceptible when 1 drop of a 0.05% aq. soln. of guaiacol is employed; 0.0025 mg. of guaiacol may be detected. H. S. PAINÉ.

New reaction of salicylic acid. PARIDE TORTI. Como. *Boll. chim. farm.* 53, 400 (1914).—A crystal of salicylic acid heated with 1 drop HNO₃ (d. 1.40) dissolves

with a yellow coloration. When suitable amts. of the substances are taken a lively reaction with development of heat and evolution of vapors takes place after some time without previous heating. Minute lemon-yellow crystals sol. in H_2O , alc. and Et_2O are produced on cooling; solns. of these crystals give an intense red coloration with an aq. 1% Fe_2Cl_4 soln. The sensibility of this reaction is about equal to that taking place between Fe_2Cl_4 and salicylic acid. The yellow coloration of the aq., alc. and Et_2O solns. of the substance obtained by the action of HNO_3 (sp. gr. 1.40) on solid salicylic acid is rendered more intense by the addition of $NaOH$ soln. and finally becomes an orange tint; the latter is restored to the original yellow color by the addition of acid.

H. S. PAINE.

Very sensitive reaction of resorcinol. SILBERMANN AND OZOROVITZ. *Boll. chim. farm.* 53, 425(1914).—Bivalent phenols react with $HCHO$ in acid soln. to produce condensation products of resinous appearance which are insol. in all the usual solvents. When resorcinol is heated with $HCHO$ after addition of a small amt. of HCl or H_2SO_4 , there is produced after a short time a white, voluminous, flocculent ppt. which assumes a fiery carmine red coloration when placed in conc. H_2SO_4 or heated with conc. HCl . The color changes to orange after neutralization or diln. with H_2O ; excess of alk. produces a Bordeaux-red coloration.

H. S. PAINE.

Ferric chloride gelatin. BOURGET. *Boll. chim. farm.* 53, 663(1914).—One hundred grams gelatin are dissolved with gentle heating in 100 g. H_2O and 100 g. glycerol. When the mixt. is perfectly liquid 50 g. Fe_2Cl_4 are rapidly added and the mixt. is heated and stirred until it becomes homogeneous. The mass is then poured upon a suitable flat surface, allowed to cool and cut into pieces.

H. S. PAINE.

Detection of impurity in dicalcium phosphate. ACHILLE TAGLIAVINI. Vercelli. *Boll. chim. farm.* 53, 696(1914).—The sample of di-Ca phosphate in question satisfied all the tests of the official pharmacopeia (Italian), although a trace of sulfates was observed in connection with these tests. The content of P_2O_5 sol. in H_2O and NH_4 citrate soln., when detd. by the method employed for perphosphate fertilizers, showed the sample to consist of 97.81% $CaHPO_4 \cdot 2H_2O$. Detn. of ammoniacal N indicated a content of 0.102% NH_3 ; the di-Ca phosphate had doubtless been prepd. from $Ca_3(PO_4)_2$ (obtained from calcined bones) and the NH_4 salts present in the latter probably remained in the di-Ca phosphate because of incomplete washing. Mg was also found to be present in combination in the sample. In view of this exam. the sample was found to be unsuited for the purpose desired, thus giving one more illustration of the fact that the tests of the pharmacopeia are not often sufficient to guarantee the purity of a product.

H. S. PAINE.

Galyi and ludyl. MOUNEYRAT. *Boll. chim. farm.* 54, 169(1915).—Galyi and ludyl are antisiphilitic arsenical preps. proposed by M. Ludyl is phenyldisulfqaminotetrahydroxyaminoarsenobenzene containing 33% of As. Galyi is tetrahydroxydiphosphoaminodiarsenobenzene containing 35.3% of As. Both preps. are yellowish powders, inodorous and insol. in H_2O and most neutral solvents; they are, however, readily sol. in H_2O to which a relatively small amt. of Na_2CO_3 has been added. These preps. are intended to be used hypodermically in doses of 0.20–0.50 g. at such intervals as to require a total of 1.20–1.50 g. for a cure. Expts. by Troisfontaines indicate that the therapeutic effects of these 2 preps. are quite satisfactory. H. S. PAINE.

Aleudrina. ANON. *Boll. chim. farm.* 54, 229(1915).—This prep. is dichloroisopropyl carbamate; it occurs as inodorous white crystals, sol. in alc., benzene, $CHCl_3$, Et_2O , and fixed oils and slightly sol. in H_2O . The compd. m. 82° . HCl is developed when the aq. soln. is heated to boiling. Acetamide is produced by treatment with dil. KOH soln.; NH_3 and aldehydes are formed by the action of concd. alkali solns. Aleud-

rina acts as a sedative in amts. of approx. 0.50 g. and has a soporific effect in amts. of approx. 1.0 g.; it has no injurious action on the organism. H. S. PAINE.

Arsenical cod liver oil. JANNSEN. *Giorn. farm. chim.* 62, 122(1913).—One-half g. arsenious acid is dissolved in 20 g. warm abs. alc. after addition of several granules of K_2CO_3 . The filtered soln. is mixed with 1500 g. cod liver oil and heated on a H_2O bath until the alc. is completely eliminated. A clear prep. is obtained which contains approx. 0.005 g. As_2O_3 for every 30 g. of oil. H. S. PAINE.

Alkaline iodide hydrogen peroxide. ANON. *Giorn. farm. chim.* 62, 359(1913).—The formula for this new antiseptic is as follows: 3 g. NaI, 100 g. H_2O_2 soln., 100 g. H_2O . The soln. is prepd. as required; it has the advantage of not acting upon the surface alone, inasmuch as the I becomes intimately fixed upon the tissues as the latter are attacked by the nascent O. This antiseptic also has a deodorizing action. H. S. PAINE.

A preparation with bismuth base for the examination of the stomach. RÂCHOU. *Giorn. farm. chim.* 62, 359(1913).—In view of the fact that all the preps. with a base of Bi carbonate which are employed in connection with the radioscopic exam. of the stomach lack the necessary homogeneity and stability required by such material, R. proposes the following formula which may be rapidly and easily prepd.: 120 g. Bi carbonate, 20 g. gum arabic, 3 g. gum tragacanth, 150 cc. simple sirup, 350 cc. H_2O , sufficient orange flowers H_2O to aromatize. The milk of Bi thus prepd. remains perfectly homogeneous *in vitro* for approx. 24 hrs. A distinct stomachal umbra without any trace of sediment may be obtained with this prep. $\frac{1}{2}$ hr. after ingestion. H. S. PAINE.

Dried blueberries. C. Y. PALM. *Svensk Farm. Tidskrift* '19, 217(1915).—Three clean samples of blueberries from local drug stores were examd. and reported as follows: dry matter 75.8–78.0, ash 1.28–1.34, sugar 26.9–34.6, non-volatile free acids 3.8–4.2, water-sol. ext. 58.0–60.1%. A. R. R.

Rapid assay of pepsin. DELAUNAY AND BAILLY. *Bull. soc. pharm.* 1915, I; *Schweis. Apoth. Ztg.* 53, 297(1915).—Dissolve 0.5 g. edestin in 100 cc. HCl, filter and add 0.02 g. of pepsin to 20 cc. of this soln. warmed to 50° , then place the mixt. in H_2O at 17° and add 30 drops of HNO_3 . No cloudiness or ppt. will be seen when the pepsin conforms to the demands of the French Codex. A very slight opalescence is admissible. S. WALDBOTT.

A substitute for tincture of iodine. SCHUHMACHER. *Deut. med. Wochschr.* 1915, 220; *Schweis. Apoth. Ztg.* 53, 281(1915).—A 5% soln. of Br in $CHCl_3$ or eventually CCl_4 may replace tinct. of I as skin disinfectant (*Münch. med. Wochschr. Feldärz. Beilage* 1915, 132). Or, a successive brushing of the wound with the following 2 solns. has the same effect: (I) KI 2, H_2O 5, EtOH 5 parts; (II) $(NH_4)_2S_2O_8$ 2, H_2O 5, EtOH 5 parts. S. WALDBOTT.

Some drug adulterations. GUSTAV BACHMAN. *Midland Druggist* 49, 155–6 (1915).—Eleven samples each of official NH_4OH , dil. HCl and sweet spirit of niter from Minnesota pharmacies were examd. With NH_4OH , the % of NH_3 ranged from 5.78–11.24, 6 samples being close to the required 10%. With HCl, 5 samples were above strength (10.7–12.0%) 2 were correct and 4 were below strength (2.25–9.26%). The latter no doubt were made by dilg. concd. HCl with 9 vols. of H_2O . Only 1 sample of sweet spirit of niter was up to the standard of 4%. S. WALDBOTT.

Berledets. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 79–80(1914).—Rept. of a 2nd examn. (cf. C. A. 8, 2029). Hexamethylenamine 6.0, H_3BO_3 43.3, KH_2PO_4 18.3, starch 16.5, lactose 15.0 and flavoring (by difference) 0.9%. Each tablet contains approx.: 1 grain of hexamethylenamine, $6\frac{1}{2}$ grains H_3BO_3 , and 3 grains of KH_2PO_4 . L. E. WARREN.

Dr. W. B. Caldwell's syrup pepsin and herb laxative compound. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 80-82(1914).—Ingestion produced physiologic effects like those produced by phenolphthalein; consequently the product was examd. for that substance. Phenolphthalein was absent. A prepn. of senna was found, also small quantities of a salicylate, probably Na salicylate. There were no indications of the presence of pepsin.

L. E. WARREN.

Dunham's specific for whooping cough. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 82(1914).—Substances such as are usually found in cough and whooping cough remedies, such for example as NH_4HCl , antipyrine, ext. of glycyrrhiza, opium derivs. and tartar emetic were absent. The prepn. appeared to be a colored and sweetened mucilage.

L. E. WARREN.

Elmiton. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 82-4(1914).—Sold as a fat reducer. Caffeine, rhubarb, Ph salicylate and organically combined I were found in 2 specimens. In a 3rd I was not found. The I probably had been derived from thyroid or bladder-wrack.

L. E. WARREN.

M. I. S. T. No. 2 nerve tonic. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 84-7(1914).—The initials are said to mean "Murray's Infallible System Tonic." Brownish black cylindrical masses, weighing about 0.33 g. each, each inclosed in a gelatin capsule. Aloes, Hg, powdered glycyrrhiza, powdered althaea, starch, traces of Ca, a P compd., oil of wintergreen and a little sand were found. Nux vomica, cascara, phenolphthalein, saline purgatives, soap, iodides and Zn_3P_2 were not found. About 4% of Hg was present.

L. E. WARREN.

Nikola. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 87-8(1914).—Nikola is a "bathing compound weight reducer." Analysis gave Na_2CO_3 82.25 and H_2O 13.85% Traces of NaCl were present. The prepn. is evidently a com. grade of $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$.

L. E. WARREN.

Plasmon, plasmon powder and plasmon milk powder. W. A. PUCKNER. *Lab. Rep. Am. Med. Assoc.* 7, 88-92(1914).—The 3 substances are essentially identical. Each appears to be a crude milk casein rendered partially sol. by treatment with an alkali. Plasmon powder: H_2O 7.43, ash 9.06, P 1.24, N 12.09, protein (N 6.38) 77.10, Na 2.68, fat 0.38% and lactose traces. Plasmon milk powder: H_2O , 7.43, ash 7.54, P 1.25, N 12.20, protein (N 6.38) 77.87, Na 2.01, fat 0.19% and lactose traces.

L. E. WARREN.

Worner's oil liniment. W. A. PUCKNER. *Rep. Lab. Am. Med. Assoc.* 7, 93(1914).—A murky oil. It probably contains oil of turpentine, menthol, oil of sassafras and liquid paraffin.

Factors influencing the stability of hypochlorite solutions. M. L. GRIFFIN AND J. HEDALLEN. *J. Soc. Chem. Ind.* 34, 530-3(1915).—An exptl. study reported in detail. CaO sludge alone, as well as 75 and 50% sludge, will give a bleach liquor of a fairly high availability when well protected by an excess of Ca(OH)₂ (over 10%), even in the form of sludge. The influence of Al(OH)₃ largely depends upon how well the liquor is protected by the alk. Ca base. When as much as 10 g. per l. of this impurity are added the availability of the Ca(ClO)₂ soln. will be depressed even in the presence of a large excess of Ca base. Fe(OH)₃, even in small quantities, rapidly reduces the availability of Ca(ClO)₂ soln., leaving a pinkish liquor; its influence is proportional to the amt. present. Both the alkaline earths and the alkali metals gave practically equally

stable hypochlorite solns., with an availability above 98% after standing 3 days. On passing Cl into $\text{Mg}(\text{OH})_2$ under the same conditions as in the case of $\text{Ca}(\text{OH})_2$, the hypochlorite at first formed will change rapidly to chloride and chlorate with about 16% of the total Cl present as chlorate. Effects of Mg: (1) The $\text{Mg}(\text{OH})_2$ has no effect upon the availability of $\text{Ca}(\text{ClO})_2$ solns. provided the liquor is protected by at least 5% Ca base. (2) The $\text{Mg}(\text{OH})_2$ sustains the stability of the hypochlorite solns. to some extent when the excess Ca is between the limits of 0% and 5%. (3) Even a large excess alkalinity in the form of $\text{Mg}(\text{OH})_2$ is incapable of maintaining the stability of $\text{Ca}(\text{ClO})_2$ when the Ca is exhausted. (4) The absorption of Cl after the Ca is consumed is very incomplete. (5) When leading Cl into a mixt. of $\text{Ca}(\text{OH})_2$ and $\text{Mg}(\text{OH})_2$, no Mg will go in soln. before all of the Ca is exhausted. With small amts. of Fe, Cr, Mn, Ni, or Co the bleach liquor was very unstable, even when well protected with an ample excess of $\text{Ca}(\text{OH})_2$. The conc. of the liquor has very little effect upon its stability. Stable bleach liquor of lower density is usually greenish in color, while at a high density it is yellowish. Bleach liquor settles more slowly with increasing conc. Temp. has very little effect upon the availability, it being decreased only 2.2% by raising the temp. from 30° to 90°. A study of methods of analysis showed that the Bunsen method gives the most accurate results, but cost of KI is a disadvantage. The Penot and Mohr methods give reasonably concordant results, which were about 0.6% lower than those with the Bunsen method. There was no indication that the electrolytic bleach liquor behaved differently from bleach liquor made from the powder. The amt. of I introduced in Mohr's method was without influence upon the results. The length of time used in titrating the samples has no effect, provided proper correction is made for the adhesion of the normal soln. to the buret. The method used for the analysis of a mixt. of hypochlorite, chloride, and chlorate is given in Sutton's "Volumetric Analysis" (10th ed. p. 178). In the daily bleach plant analysis chloride and chlorate are not detd. separately, so the shortened method is as follows: pipet 5 cc. of the liquor to be tested into a pressure flask and add about 25 cc. of a soln. containing 40 g. of $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ and 40 cc. H_2SO_4 per l. Heat to about 100°, cool slightly, and then add the Ag; filter, wash the ppt., and titrate the excess Ag with KCNS. The available Cl is detd. in a sep. sample by the Bunsen method. Tables of results are given. F. W. SMITHER.

An investigation of the extraction of potash from feldspar. E. H. QUINNEY. *Chem. Eng.* 21, 171-3 (1915).—Thesis detailing investigation by Q. in conjunction with M. F. Coolbaugh at South Dakota State School of Mines, preliminary to securing U. S. Patent 1,125,007 (cf. C. A. 9, 696). WM. W. WINSHIP.

Possible sources of potash. C. G. CRESSWELL. *J. Soc. Chem. Ind.* 34, 387-93 (1915).—C. gives a brief history of the German Potash Syndicate and discusses all available sources of K, whether of present commercial utility or otherwise, in view of the shortage of German salts. Considerable space is devoted to the extn. from feldspar, mica, etc., and the following possible sources are also covered: sea water, kelp, plant and wood ashes, saltpeter, K lakes and deposits, alunite, waste sulfite pulp liquors, sugar residues and wool scouring. WM. W. WINSHIP.

Chemicals used in shop processes requiring heat. E. H. FISH. *Am. Machinist* 42, 999 (1915).—The prepn. of a large number of fluxes and chemicals now used in steel treating is described. Purposes and properties of each are also discussed.

C. G. F.

Science and industrial problems. A. W. CROSSLEY. *Chem. Trade J.* 56, 459-61, 483-5, 503-5 (1915).—A lecture. The need of coöperation between the research chemist, industrial chemist and mfr. and the advantages of industrial organizations are emphasized. The problems discussed are: utilization of atm. N, hydrogenation of oils, and

org. colors. Analytical data and tables are given from the literature and curves constructed from this data. F. W. SMITHER.

The future status of the German chemical industry. O. NAGEL. *Chem. Ztg.* 39, 385-6(1915). J. H. MOORE.

Patents, designs and trade marks (temporary) rules, Aug. 21, 1914. *J. Soc. Chem. Ind.* 34, 585(1915).—Reproduction of rules with reference to the above subjects adopted by the Brit. government to apply during the present war period. E. J. C.

Yield of nitrogen in coal (SIMMERBACH) 21. Filter for waste gases from ammonium sulfate manufacture (REINHARD) 21.

Brit., 3,625, Feb. 12, 1914. O. G. TRIGG. A cement for preserving Fe or steel consists of a mixt. in the following proportions: chalk 8 oz., colophony resin 2 oz., pumice stone 8 oz., shellac 1 lb., Stockholm tar 1 gal., methylated spirit 1 qt., and graphite 4 oz. The cement may be put on with a brush or trowel.

Brit., 4,435, Feb. 20, 1914. B. C. HINMAN. In purifying liquids, pptg., flocculating, or like reagents are added to a uniform or variable flow of liquid by being dissolved or suspended in a liquid in a vessel from which the mixt. is displaced by progressive diln. with a predetd. increasing proportion of the flowing liquid, the discharge being mixed with the main body of liquid.

Brit., 4,628, Feb. 23, 1914. K. BOMHARD and G. KONIG. The specific gravity of a gas is estimated by detg. the resistance encountered by a body rotating or otherwise moving in it. Cf. C. A. 8, 1892.

Brit., 4,707, Feb. 24, 1914. I. MERRELL. Drying liquid by air in a desiccating chamber, part of the resulting powder remaining in this chamber and part being received in alternate or successive collecting-chambers which, when not collecting, discharge the powder to a receptacle which also receives that from the desiccating chamber, a uniform product being obtained.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Report of the glass research committee of the Institute of Chemistry. *J. Soc. Chem. Ind.* 34, 424-5 (1915); *Analyst* 40, 263-6 (1915).—The following formulas are suggested as the result of some 400 expts. Soft glasses suitable for ordinary chem. lab. ware: (1) SiO_2 67.0, Na_2CO_3 34.2, $CaCO_3$ 11.6, Al_2O_3 6.5 parts; (2) SiO_2 67.0, Na_2CO_3 29.0, $CaCO_3$ 9.6, CaF_2 1.6, Al_2O_3 8.3, B_2O_3 2.0 pts. A resistant glass suitable for pharmaceutical purposes, etc.: (3) SiO_2 67.0, Al_2O_3 10.0, $CaCO_3$ 12.5, MgO 0.5,

KNO₃ 1.0, Na₂CO₃ 17.0, B₂O₃ 8.0 pts. Combustion tubing: (4) SiO₂ 68.2, Al₂O₃ 6.2, BaCO₃ 8.8, CaCO₃ 13.0, KNO₃ 4.3, Na₂CO₃ 5.5, B₂O₃ 5.5, CaF₂ 1.0 pts.; (5) SiO₂ 68.2, Al₂O₃ 6.2, BaCO₃ 8.8, CaCO₃ 14.2, KNO₃ 4.3, Na₂CO₃ 5.5, B₂O₃ 5.5 pts. Miners' lamp glasses: (6) SiO₂ 65.0, Al₂O₃ 1.0, CaCO₃ 0.6, As₂O₃ 2.0, Sb₂O₃ 1.0, KNO₃ 3.0, Na₂CO₃ 14.0, B₂O₃ 24.0 pts.; (7) SiO₂ 65.0, Al₂O₃ 1.0, CaCO₃ 0.6, As₂O₃ 2.0, Sb₂O₃ 1.0, KNO₃ 3.0, Na₂B₄O₇ 26.68, B₂O₃ 5.5 pts. Resistance glass: (8) SiO₂ 65.5, Al₂O₃ 2.5, MgO 5.0, ZnO 8.0, Na₂CO₃ 10.2, Na₂B₄O₇ 13.0 pts. Combustion tubing: (9) SiO₂ 72.0, Al₂O₃ 10.0, CaCO₃ 11.0, MgO 0.5, KNO₃ 3.0, Na₂CO₃ 11.2, B₂O₃ 7.2 pts. Soft soda glasses: (10) SiO₂ 68.0, Al₂O₃ 4.0, CaCO₃ 12.8, KNO₃ 14.5, Na₂CO₃ 26.0 pts.; (11) SiO₂ 68.0, Al₂O₃ 4.0, CaCO₃ 12.8, K₂CO₃ 10.0, Na₂CO₃ 26.0 pts. G. E. BARTON.

Notes on glass. ANON. *J. Soc. Chem. Ind.* 34, 210-2(1915).—The results of various tests made by the National Physical Lab. on German glasses are given including Jena 59", Jena 16", Schott und Gen., Jena Original and "New," Resistance "R," Kavalier's Bohemian, Thuringen, Jena incandescence gas, Miners' lamp A 1 B, Miners' French lamp (2 samples), Austrian lamp "Sun Brand." The general conclusion is reached that most if not all of the special properties formerly attributed to the use of layers of different comps. are the result of special heat treatments of the various objects at the time they are blown. G. E. BARTON.

The composition of some types of chemical glassware. F. W. BRANSON. *J. Soc. Chem. Ind.* 34, 471-2(1915); cf. 2 preceding abstrs.—Demands in England for chem. glassware, especially beakers and flasks and miners' lamp glasses, have been urgent, especially for the Ordinance Works. The Brit. Lab. Ware Assoc., Ltd., has adopted for this work a zinc boro-silicate. Tests of the glass in use have been satisfactory. The following table shows new analyses. In the 2nd column is given a hard Na glass now being used in place of the Kavalier K Na glass, given in the 1st column.

	Kavalier.	Hard Na glass.	Jena combustion tube.	Kavalier combustion tube.	Jena miners' lamp glass.
SiO ₂	75.96	76.18	66.90	79.57	73.08
Al ₂ O ₃	0.40	2.86	6.38	0.32	1.98
Fe ₂ O ₃	0.08	0.07	0.22	0.038	0.15
CaO	8.48	4.52	7.94	7.80	Tr
MgO	0.14	0.14	0.61	0.11	Tr
K ₂ O	7.48		2.40	11.60	
Na ₂ O	7.34	16.43	1.25	0.66	7.76
CaO			7.27		
B ₂ O ₃			7.22		17.22

The Jena miners' lamp glass batch was found pasty even at high temps. and difficult to work satisfactorily; changes had to be made. C. H. KERR.

The use of barium compounds in glass. ALEXANDER SILVERMAN. *J. Soc. Chem. Ind.* 34, 399-402(1915).—This article gives a brief historical survey of the subject and quotations from letters received in reply to a circular letter of S. The conclusion is that while at present Ba compds. are used to only a limited extent a much wider use could to advantage be made of them if the price could be reduced. J. E. B.

The causes of the opalescence of glass. JUDSON G. SMULL. *J. Soc. Chem. Ind.* 34, 402-5(1915).—It is concluded that opacity in glass is due (1) to the sepn. of either silica or alumina or both in a very finely divided, probably colloidal, form in the glass; (2) the most suitable condition for this sepn. is a glass of low m. p., that is, one containing lead, where the silica and alumina will remain suspended for some time before going into soln.; (3) the sepn. of silica and alumina is effected by (a) the use of silicates, such

as feldspar, in conjunction with a fluoride; (b) by a double fluoride, such as cryolite with or without feldspar; (c) by silicofluorides, with or without feldspar; (d) by a fusion of the major ingredients of a glass, with the addition afterwards of a fluoride and other desired substances to the fused portion.

G. E. BARTON.

The use of nitrates in the glass industry during the war. R. *Sprechtsaal* 48, 41-2(1915).—The conclusion is reached that in the case of all except lead glasses the use of nitrates is not absolutely essential. In the lead glasses more expensive substitutes are recommended, particularly $\text{Na}_2\text{BO}_3 \cdot 4\text{H}_2\text{O}$.

G. E. BARTON.

Decorating glass with iridescent coatings. RAPHAEL ED. LIESEGANG. *Sprechtsaal* 48, 2-3(1915).—Artificial pearls may be made by utilizing the iridescence obtained from the diffusion of Na_2PO_4 , $\text{Ca}(\text{NO}_3)_2$ or Ag_2CrO_4 soln. in gelatin in place of the common soln. of fish scales. The glass is coated with 10% gelatin soln., allowed to dry partially and then a small amt. of Na_2PO_4 , $\text{Ca}(\text{NO}_3)_2$ or Ag_2CrO_4 added. The coating must be slowly dried. The iridescence seems to be an optical phenomenon caused by the formation of extremely fine parallel wrinkles on the gelatin. J. B. P.

Antimony oxide as a decolorant and refining agent for glass. L. SPRINGER. *Sprechtsaal* 40, 97-8, 106-7(1915).—S. gives a review of the opinions *pro* and *con* concerning the use of Sb_2O_3 for the above purposes. His conclusion is that it is of no value as a refining agent and is not a decolorant for leadless glass. It imparts a yellow tint to lead glasses due to formation of lead antimonate.

C. S. K.

Glass shades for incandescent gas lighting. ANON. *Pott. Gaz.* 40, 200-1(1915).—The glass described is intended to give to gas light an appearance of daylight. It is known as a lead-potash glass. The greatest difficulty encountered is in making it of the desired thickness, 5% variation in thickness changing the daylight value considerably. The spectrum of the light passing through this glass is practically ideal.

C. S. K.

Mosaic glazing and the electric current. FRIEDRICH HUTH. *Diamant* 37, 225-6, 245, 265-6, 285, 305-6(1915).—Descriptive of the electrolytic methods of setting and binding together mosaics and stained glasses.

J. B. PATCH.

The introduction of the batch in pot furnaces. KA. L. *Glasind.* 26, No. 7-8, 9 illus.(1915).—Polemic. Cf. C. A. 9, 700.

J. B. PATCH.

The influence of white-ware-glaze-composition upon the development of under-glaze-colors. KARL JACOBS. *Sprechtsaal* 48, 98-100, 107-9(1915).—The under-glaze colors studied were Victoria green and chrome-tin pink. The 40 glazes studied are represented by the typical formula: 0.40 PbO , 0.40 CaO , 0.15 K_2O , 0.05 BaO , 0.25 Al_2O_3 , 0.20 B_2O_3 , 2.60 SiO_2 . The work showed that: (1) Victoria green is much more sensitive to the over-glaze compn. than the chrome-tin stain. (2) An over-glaze should contain no BaO . (3) B_2O_3 enhances the destructive action of BaO on colors. It should not exceed 0.10 equiv. if the CaO is below 0.40. If the equiv. of the latter exceeds this figure the B_2O_3 may be as high as 0.20 equiv. (4) A high CaO content (at least 0.40) is favorable to under-glaze colors.

C. S. K.

Kaolin. WILSON W. HUGHES. *Mining Sci. Press* 110, 947-50(1915).—Sixty % of the kaolin used in U. S. is imported. N. C. kaolin was exported to England before English deposits were developed. Analyses of Chinese, English, French and American kaolins are given. The usual washing process is described in detail.

C. H. KERR.

Chemical facts regarding some Tertiary and pre-Tertiary clays. H. MÜLLER. *Sprechtsaal* 48, 9-10, 17-19, 25-7, 76-7, 85-7(1915).—M. describes results of work done on a number of clays. The compn. of the different types of clay substance has been

detd. M. refers to 2 kinds of clay substance: that sol. in HCl, or the allophanes, and that sol. in H_2SO_4 or the feldspathic material. Many tables of analyses are given.

C. S. K.

Further notes on the refractory properties of zirconia. H. C. MEYER. *Met. Chem. Eng.* 13, 263-6(1915).—An av. sample of natural zirconia shows the following analysis: ZrO_2 84.1, SiO_2 7.74, Fe_2O_3 3.10, TiO_2 1.21, Al_2O_3 0.66, loss on ignition 2.72%. Bonded with 5% Warrior Ridge fire clay, this ore stands cone 32 easily. The material alone shows a linear shrinkage of 9% when fired to 2600° F. It is claimed that the natural zirconia develops very fair plasticity upon wet grinding. A mixt. of 93% zirconia (95% pure) and 7% Dry Branch kaolin had a firing linear shrinkage of 12% at 2600° F. The work of selecting a suitable binder is described, sorrel cement, phosphoric acid and sodium silicate being tried. Ultimately, water-ground zirconia was found to be the most satisfactory. A fire clay bond lowers the m. ps. too far to be entirely satisfactory. Zirconia has a considerably lower thermal cond. than magnesite and quite probably the lowest of any available material that will stand 1800° C. At this temp., zirconia bonded with clay softens to quite an extent. A brick made from this mixt. can nevertheless be considered among the 6 highest refractories.

C. S. K.

Refractories of the Rocky Mountain region, and some of their products. J. C. BAILAR. *Met. Chem. Eng.* 13, 257-8(1915).—A most superior fire clay deposit marks the eastern boundary of the Rocky Mts. in Colo. It is accompanied by large bodies of shale and plastic clay suitable for building brick, terracotta, roofing tile, etc. Mention is made of the manuf. of porcelain cooking utensils and chem. porcelain. The manuf. of enameled brick is described; this is featured by the enamel being applied to the clay bar as it issues from the machine, and by the brick being fired but once. This article does not deal with refractories.

C. S. K.

Examination of fire bricks. J. S. BECKETT. *Met. Chem. Eng.* 13, 136(1915).—B., commenting on Patterson's article (cf. *C. A.* 9, 959), suggests a procedure for detg. SiO_2 , the method being modelled largely after the one described by W. F. Hillebrand in *Bull.* 422, U. S. G. S. The method takes care, almost automatically, of the impurity of either the SiO_2 or Al_2O_3 ppt. and insures the presence of all the TiO_2 in the H_2SO_4 soln., whether or not any of it has been carried down previously with the SiO_2 .

C. S. K.

Utilization of blast furnace slag. ANON. *Iron Coal Trades Rev.* 90, 301(1915).—Results of tests of bricks made from mixts. of granulated blast furnace slag and $Ca(OH)_2$, dried in the open air or steamed under pressure. In quality they are equal to good clay or shale bricks.

Electrical precipitation (CREIGHTON) 4.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Petrographic study of portland cement. R. J. COLONY. *School Mines Quarterly* 36, 1-21(1914).—A study of thin sections of hydrated cement. The hydration products are an amorphous constituent which may exhibit incipient or partial recrystn. and cryst. $Ca(OH)_2$ (cf. Klein and Phillips, *C. A.* 8, 3848). The texture of the cement matrix should be exceedingly fine and carbonization should not exist to any great extent. Alit is an hydratable constituent while the occurrence in the cement matrix

of fragments of residual clinker of belit comp. in conjunction with fully developed amorphous constituent seems to be indicative of properly burned cement. A. A. K.

The constituents of portland cement clinker. G. A. RANKIN. *Geophys. Lab., J. Ind. Eng. Chem.* 7, 466-74(1915); *Concrete-Cement Age* 6, C. M. S. 55-63(1915).—R. gives a review of the data obtained in the study of the ternary system $\text{CaO-SiO}_2\text{-Al}_2\text{O}_3$, as it relates to the constitution of portland cement. Well burned clinker made up of pure oxides will consist largely of $3 \text{ CaO} \cdot \text{SiO}_2$, $2 \text{ CaO} \cdot \text{SiO}_2$, and $3 \text{ CaO} \cdot \text{Al}_2\text{O}_3$ with small quantities of CaO and $5 \text{ CaO} \cdot 3 \text{ Al}_2\text{O}_3$. Both white and gray cement clinker is composed largely of the above compds. These do not form solid solns. but have definite optical constants. MgO and alkalies are apparently taken up in solid soln. by $3 \text{ CaO} \cdot \text{Al}_2\text{O}_3$ and $2 \text{ CaO} \cdot \text{SiO}_2$ (cf. Bates, *C. A.* 7, 690, 1406; Klein and Phillips, *C. A.* 6, 3172). The % of MgO and alkali is so low that the identity of these compds. is not obscured. The minor constituents do, however, play an important role in making possible the formation of a flux at low temp., thus assisting the combination of CaO with Al_2O_3 and SiO_2 and may be considered as catalyzers. Pure cement requires a temp. of 1650° for burning; a white cement (2.4% MgO , Fe_2O_3 , etc.) requires 1525° and a gray cement (with about 6.7% minor constituents) requires 1425° for producing a clinker giving sound cement. That most commercial clinker approaches a condition of equil. is shown by the fact that at most only small amts. of CaO and $5 \text{ CaO} \cdot 3 \text{ Al}_2\text{O}_3$ are noted. Hydration of cement constituents is already being investigated (cf. Klein and Phillips, *C. A.* 8, 3848) and should lead to the detn. of the compds. which on setting give the most desirable qualities. A. A. KLEIN.

Chemical similarities of hydraulic cements. G. B. UPTON. *Sibley J. Eng.* 29, 220-2(1915).—A portland-, an Fe ore- and a natural cement are reduced to $\text{CaO} \cdot \text{Al}_2\text{O}_3$ and SiO_2 with the assumption that Fe replaces Al and MgO replaces CaO . It is presumed that these cements if completely burned would have $\frac{1}{3}$ CaO as $3 \text{ CaO} \cdot \text{Al}_2\text{O}_3$ and $\frac{2}{3}$ as Ca silicates. Natural cements have no $3 \text{ CaO} \cdot \text{SiO}_2$ while portlands have $\frac{1}{3}$ tricalcium silicates and $\frac{1}{2}$ dicalcium silicates. It is suggested that the CaO be lowered in cements until only $2 \text{ CaO} \cdot \text{SiO}_2$ and $3 \text{ CaO} \cdot \text{Al}_2\text{O}_3$ are present in order to form material more like natural cement. A. J. PHILLIPS.

British portland cement making machinery. ANON. *Engineer* 119, 552-4(1915).—An engineering description. A. A. KLEIN.

Effect of proportions on density and strength of gravel concrete. R. W. CRUM. *Eng. Contrg.* 43, 314-15(1915).—Progress report on density and strength determinations of concrete from sieve analyses, the method of voids being considered useless. A few tests are given. A. J. PHILLIPS.

Effect of the duration of mixing on the strength of concrete. H. H. SCOFIELD. *Eng. Contrg.* 43, 78-9(1915).—Seven series of compressive test specimens of 1:2:4 stone and sand and 1:5 gravel mixes were made. The results showed that max. strength and max. modulus of elasticity are obtained when materials are mixed 10-18 min. There was little difference whether mixed 0.5 min. or 2-3 min. but by increasing to 8-10 min. a marked increase obtains. A. J. PHILLIPS.

Effects of alkali on concrete drain tile. C. E. SIMS AND G. P. DIECKMAN. *Concrete-Cement Age* 6, 278-80(1915).—The tile consisted of 1:4 mix, cured 3 days. They cracked longitudinally and were coated in the interior with a lime-like deposit which consisted mainly of CaSO_4 and MgSO_4 . Disintegration is due to the crystn. of these salts and its accompanying expansion. Repeated wettings and dryings concentrate the salts in the concrete and accelerate the disintegration. A. A. KLEIN.

Effect of fineness of sand clay and loam on the strength of mortar. F. L. ROMAN. *Eng. Contrg.* 43, 403-6(1915).—In well graded sand the presence of fine material passing

a 50-mesh sieve causes a decrease in the strength of 1:3 mortars; in badly graded sand a small % of the same fine material causes a slight increase in strength which with larger amts. falls off again. Small amts. of clay in the sand cause a slight increase. This effect is assumed to be due to the filling of the voids by the extremely fine particles of clay carried in suspension by the mixing H_2O . The tests were made on dry mortars and do not hold true for wet mortars. Organic loam in the sand even in small amts. causes a decrease in strength; 1.5% in 1:3 tensile tests caused 15-20% decrease. Curves for 1:3 mortars are shown.

A. J. PHILLIPS.

Specification and selection of asphaltic materials for street pavement. F. O. X. McLAUGHLIN. *School Mines Quart.* 36, 30-9(1915).—The author suggests a possible solution to the problem that has arisen with the elimination of the long-term guaranty clause in specifications.

A. A. KLEIN.

Specification for a coal-tar creosote solution. P. C. REILLY. *Proc. Am. Wood Preservers' Assoc.* 1915, 158-68; cf. *C. A.* 9, 703, 854.—R. considers the adulteration of creosote oil with tar as unwise and gives his reason for thinking so.

C. A. N.

Relative resistance of various conifers to injection with creosote. C. H. TRESDALE. U. S. Dept. Agr., *Bull.* 101, 43 pp.(1914).—Cf. *C. A.* 8, 2933, 3623.

A. A. KLEIN.

Leaching of zinc salts and effects of improper drainage. F. J. ANGIER. *Proc. Am. Wood Preservers' Assoc.* 1915, 75-80.—A series of tests were made to det. the rate with which $ZnCl_2$ leaches from timber treated with the Burnettizing process. Lodgepole pine and Douglas fir ties were used. Some of the ties were seasoned 6 months after treatment and before the test for leaching was begun, and others were freshly treated and were full of the water soln. To det. the amt. of $ZnCl_2$ leached out, each tie was placed in a pan filled with water and left 24 hrs., after which it was taken out and allowed to dry 6 days. This process was repeated continuously for many months. After each soaking a measured quantity of the water was taken out from the pan and the $ZnCl_2$ detd. A study of the results shows that in carrying out a leaching test in this way less than 30% of the $ZnCl_2$ can be gotten out of the wood in nearly a year's time and that the largest part (approx. 18%) is leached out in the first 70 days. With the freshly treated ties the leaching was much more rapid, almost the entire loss being within 70 days.

C. A. NOWAK.

Treated timber for factory construction. F. J. HOXIE. *Proc. Am. Wood Preservers' Assoc.* 1915, 215-33.—The value of the mill timbers which rot each year is a sufficiently large sum to make preservative treatments well worth while. From the limited information thus far available the corrosive sublimate process appears to be best adapted to the general requirement of mill timber. F compds. have given good results in lab. expts. but no practical experience with them is available. With the few woods available for mill construction and the few fungi that commonly destroy them, it is probable that a reasonably cheap and convenient process, such as the use of corrosive sublimate in an open tank, will satisfy all requirements if applied soon enough. Probably a light treatment at the saw-mill and another after being cut to final shape and ready to be put in place in the mill frame will be found serviceable.

C. A. NOWAK.

Strength and quality of zinc chloride per tie or per cubic foot of timber. W. F. GOLTRA. *Proc. Am. Wood Preservers' Assoc.* 1915, 60-3.—It has been demonstrated that the absorption of individual ties, in the same charge, varies greatly, depending upon species and character of wood, degree of dryness, size of tie, etc. Some ties will absorb as little as 0.30 lb. salt, while others will absorb as much as 2.70 lbs. per tie. In the heavier solns. (30-60%) the influence of the temp. is small so that no account need be made of it in detg. strength by means of the hydrometer, but with solns. highly

dild. it is necessary to define the effect of temp. very carefully. For the treatment of railroad ties of all kinds with ZnCl_2 , either singly or in combination with creosote oil, G. recommends that the soln. have a strength of 3.5°Bé. at a temp. of 70°F. (equiv. to 3%). Ties of all kinds and sizes should be treated "to refusal." C. A. NOWAK.

Steaming ties. J. B. CARD. *Proc. Am. Wood Preservers' Assoc.* 1915, 103-10. —Repeated attempts were made to find a way in which green ties could be properly treated by first steaming for various lengths of time and then applying a vacuum to reduce the moisture content. C. succeeded in injecting only about $\frac{1}{2}$ the amt. of soln. into steamed green ties that he did in seasoned ties. Tests were carried out on a large number of ties from different species of wood, green and seasoned; the soln. absorbed is stated in lbs. per cu. ft. and gain in % are given in each case. It is possible that green ties, if given a prolonged steam and vacuum treatment, with the heating coils in operation, could be made to take a requisite amt. of soln. but the cost would be higher than air-seasoning and the strength of the wood injured. C. A. NOWAK.

Additional facts on treated ties. J. H. WATERMAN. *Proc. Am. Wood Preservers' Assoc.* 1915, 297-14. —W. gives his observation on railroad ties treated with: (a) full cell creosote, (b) empty cell creosote, (c) ZnCl_2 (Burnettizing process), (d) emulsion, creosote and Zn. Ties treated with (a) receive the best treatment which is known today, and if protected from mechanical wear will last 25 or more years. (b) Very little is known about this process. Most of the ties subjected to this process showed evidence of very poor treatment. (c) Ties treated with ZnCl_2 gave 11 to 12 yrs. av. life in the district around Newton, Kan. (d) 75% of red oak ties on the C. & E. I. treated with the Well-house process (Zn, glue and tannin) gave 14 yrs. of service. Ties treated with an emulsion of creosote and Zn (Card process) appear to be very satisfactory. W. agrees with Schrenk that from a practical standpoint no treatment can be considered which costs more than 25 to 30 cents. This would mean either a cheap creosote treatment, using small amts. of oil with as good penetration as can be obtained, or a Zn-creosote combination, both of which would cost 20 cents or thereabouts. C. A. NOWAK.

Treatment of red oak ties. J. H. WATERMAN, *et al.* *Proc. Am. Wood Preservers' Assoc.* 1915, 110-22. —The Committee on Miscellaneous Subjects has been considering the treatment of red oak ties during the past year. It sent out a list of questions to all members. The following conclusions were arrived at from the replies: (1) Red oak ties can be treated satisfactorily when air-seasoned for 10 months, if the summer months are included. (2) Red oak ties may also be treated satisfactorily when air-seasoned for 6 months, provided artificial seasoning is employed as an adjunct. (3) For practical reasons the period of seasoning should be the governing factor in detg. whether or not red oak ties are ripe for treatment. (a) However, if the boring test is used, the core withdrawn with an increment borer should appear dry for a depth of 2 inches. (b) If the wt. method is used the wt. per cu. ft. should not exceed 52 lbs. (c) If moisture detn. is resorted to, a test should indicate not over 22% of moisture in the ties. (4) Artificial seasoning of red oak ties apparently has not been sufficiently developed to justify a conclusion from the replies. The committee does not agree with some of the conclusions from the replies. The conclusions of the committee are: (1) Red oak ties should be air-seasoned for at least one year before an attempt is made to treat them. (2) It is practically impossible to season a red oak tie so as to render it dry throughout. (3) Same as "3" above. (4) Artificial seasoning of red oak ties fails to give the desired result. (5) Penetration of the heart wood of red oak ties can be secured with practically the same success as in the sap wood. (6) The use of an increment borer in detg. the penetration of an antiseptic treatment in red oak ties fails to give conclusive results. A tie showing insufficient penetration when inspecting the core, which is withdrawn by an increment borer, will in the majority of cases show satisfac-

tory penetration when the tie is sawed and then split. (7) Red oak ties may be treated satisfactorily with any standard process. C. A. NOWAK.

Bleeding and swelling wood block pavements. L. E. HESS. *Proc. Am. Wood Preservers' Assoc.* 1915, 397-401.—H. is of the opinion that correction of swelling and of bleeding can be secured by the use of a stable preservative oil, one that is scientifically suited to the purpose of wood block paving. Such an oil should not be subject to chem. change, should be non-volatile and should penetrate and permanently adhere to the fibres of the wood. If such an oil is used and proper treatment is given the blocks, the fibers are permanently waterproofed and swelling will not occur; because of its penetrative and adhesive character, and its low coefficient of expansion, such an oil will not exude by capillary attraction or by expansion from heat. C. A. NOWAK.

Bleeding and swelling of paving blocks. E. R. DUTTON. *Proc. Am. Wood Preservers' Assoc.* 1915, 401-5.—A discussion of a paper by Teesdale (cf. C. A. 9, 240). The principal cause of the bleeding lies in the treatment of the blocks, and if carried on properly the bleeding would be reduced to a minimum or removed almost entirely, provided no excess of oil was used in the treatment. There does not seem to be anything gained in the use of a distillate creosote oil. C. A. NOWAK.

The density of wood substance and porosity of wood. F. DUNLAP. *J. Agr. Res.* 3, 423-8(1914).—Density detns. were made with longleaf pine, Douglas fir, Pacific yew, mockernut hickory, beech, red oak and sugar maple. The results show that for practical purpose the d. of the wood substance of different species of trees may be considered as uniform, with a value of 1.54. The apparent d. of most com. woods varies from 0.3 to 0.6; it is apparent, therefore, that from 0.8 to 0.4 of the total vol. of the wood consists of empty cell space. E. J. C.

Brit., 4,349, Feb. 19, 1914. R. HOUBEN. Concrete, after being mixed with H₂O in the usual way, is mixed with an elastic powdered absorbent material, such as cork, sawdust, leather, or cotton, which has been impregnated with a liquid, such as a heated mixt. of tar and bitumen, which renders it impermeable. In an example, a mixt. of 400-500 parts of cement, 600 of sand, 1200 of broken stones, and H₂O is mixed with 80-100 parts of a mixt. consisting of 6 parts of sawdust and 5 of a mixt. of 10 parts of bitumen and 100 of tar. The product is used for covering large surfaces such as roads.

Brit., 4,805, Feb. 24, 1914. A. ABRAHAM. In the process, described in 10,478, 1912 (C. A. 7, 3636), of waterproofing soil or rock by the injection of 2 substances which form in the pores an insol. ppt. of large sp. vol. a neutral liquid, preferably H₂O, is injected between the injections of the 2 chemicals.

Can., 160,501, Feb. 9, 1915. S. DAVIDSON. Drying artificial stone or wet molds by filtering the moisture into the molding sand and extracting the moisture from the molding sand through a filter by mechanical means.

Fr., 467,926, Jan. 24, 1914. COMP. FRANÇ. D'INJECTION. Process of hardening and preserving wood intended especially for wood-plaster, consisting in impregnating or incorporating under pressure a naphthalene (70-80%) melted above 90°, with the addition of creosote, tar, schist-oil, and the like.

Ger., 281,866, July 29, 1913. E. TRAEGER. Mfg. decorated wall-, floor-, or roof coverings from linoleum-like masses.

J. D. PENNOCK.

Yield of nitrogen in coal. OSKAR SIMMERBACH. *Colliery Guardian* 109, 1020 (1915).—The temp. of formation of NH₃ varies with different coals from 800 to 900°.

Decompn. of NH_3 during gasification begins at 800° and increases with rising temp. The quantity of $(\text{CN})_2$ formed amounts to 1.5% of total N and to 5% of the NH_3 . H_2O lowers the $(\text{CN})_2$ yield and raises that of NH_3 , while high gas velocity favors the formation of $(\text{CN})_2$. The size of the grain of coal has no effect upon the NH_3 yield.

Fuel supply contracts and progress of scientific methods of purchase and control in America and Europe. J. B. C. KERSHAW. *Met. Chem. Eng.* 13, 393-6(1915).—The article gives the methods in use in Germany, Switzerland, the United Kingdom and America for sampling and testing fuels in transit, or when discharged at the consumers' works. Some samples are given of forms of contracts in which the price paid for the fuel is made dependent either on the calorific value or upon the % of ash.

C. A. COLE.

Coal fields and coal resources of Canada. D. B. DOWLING. Canada Dept. Mines, *Memoir* 59, 157 pp. (1915).—Estimates show that the British Empire possesses nearly one-quarter of the world's reserve supply of coal. An estimate of the amt. of available coal shows 1230 billion metric tons distributed through the various provinces of Canada. The location and descriptions of the coal fields in the different districts are given. The detn. of the moisture, the proximate and ultimate analyses of the dry coals and the calorific value (B. t. u.) are included.

R. L. SIBLEY.

Coal mining in Mexico. E. O. F. BROWN. *Iron Coal Trades Rev.* 90, 525-8 (1915).—The coal production of Mexico is practically limited to mines in Coahuila, within 100 miles of the U. S. border. It is estd. that 1,850,000 metric tons were produced in 1911. Representative analyses show that ash varies from 20 to 28%, volatile matter from 20 to 23%, and fixed C from 50 to 60%. The S content ranges from 1 to 2%. At Lampacitos a battery of 36 Koppers ovens has been installed to coke the washed fines which constitute 40% of the gross output; the product is of poor quality.

H. L. OLIN.

Fohr-Kleinschmidt briquetting process. T. DACH. *Colliery Guardian* 109, 310(1915).—Pitch in an unbroken condition is heated by a steam coil to 100° and run into a melting pan proper where it is heated to 130 – 170° by direct flame. It is next led to a steam-heated atomizer where it is blown in a spray to the mixing drum. The coal-pitch mixt. is kneaded, heated and pressed.

A problem of the modern city. W. F. M. GOSS. *Proc. Eng. Soc. Western Penn.* 31, 229-37(1915).—A general discussion of the problem of smoke abatement.

H. L. OLIN.

The determination of benzole in gas. A. KRIGER. *J. Gasbel.* 58, 61-4(1915).

—The method is suitable for the analysis of purified coke oven gas containing as little as 2 g. benzole per l. By "benzole" is meant the mixt. of benzene and its homologs as contained in the gas. The gas is led through the absorption vessel at the rate of 40 l. per hr. Two absorption vessels are used with 50 cc. of paraffin oil in each. The oil is not allowed to take up over 0.8 g. benzole in 50 cc. This is equiv. to a factor of safety of 4. The vessels must be cooled to -18 to -20° ; also care must be taken that they are filled with gas before the first weighing, and that air does not diffuse in after the absorption while the vessels are warming for the second weighing. Weighings need only be made to 0.01 g., and the detn. may be made by untrained assistants. The essential point in the absorption vessel is the tube filled with glass beads. Even with very tall Drehschmidt bottles and a very slow current of gas, several bottles were necessary to

prevent loss from oil spray. With the app. illustrated, only a trace is caught in the second bottle and none in the third.

W. L. BADGER.

The recovery and fractionation of benzole from coal gas. W. DIAMOND. *Iron Coal Trades Rev.* 90, 638-9(1915).—The amt. of crude benzole in coke oven gas varies from 2 to 3 gal. per ton of coal. It consists of C_6H_6 and its homologs, toluene, xylene, naphthalene, CS_2 , etc., in varying proportions. After the removal of NH_3 the gas goes through the benzole scrubbers where it is washed with coal-tar creosote oil, dils. 1.04, which absorbs benzole readily. The wash oil goes to the distillery where benzole is sepd. in continuous stills consisting of preheater, heater, still and condenser. The product is further purified by washing with H_2SO_4 and NaOH, and fractionation.

H. L. OLIN.

The distribution of heat in the cylinder of a gas engine. A. H. GIBSON AND W. J. WALKER. *Iron Coal Trades Rev.* 90, 713-4(1915).—Expts. made at University College, Dundee, on a gas engine with a cylinder diam. of 11 in. and a stroke of 19 in. gave the following results: Mechanical efficiency (1) increases with increasing loads; (2) diminishes as the ratio of air to gas increases; (3) diminishes as the speed increases; (4) is sensibly independent of the compression ratio. The max. efficiency obtained with a 7 : 1 mixt. and a speed of 150 r. p. m. was 88%. At the normal speed of 200 r. p. m. with the same mixt. it was 85%. The thermal efficiency as measured on the i. h. p. (1) increases with the load; (2) attains a max. with an air to gas mixt. of 10 : 1; (3) increases slightly as the speed increases; (4) increases as the compression ratio increases. At a speed of 200 r. p. m. with a compression ratio of 5.70, the efficiency was 35.3%. The thermal efficiency on b. h. p. (1) increases with the load; (2) attains a max. with an air to gas ratio of 8 : 1; (3) diminishes as speed increases; (4) increases with the compression ratio. At a speed of 200 r. p. m. and a compression ratio of 5.70, the efficiency was 28.6%. The ratio of the actual thermal efficiency measured on the i. h. p. to the corresponding air-cycle efficiency (1) increases with the load; (2) has a max. value when the ratio of air to gas is 10 : 1; (3) increases slightly with the speed; (4) is sensibly independent of the compression ratio. At a speed of 200 r. p. m. the efficiency ratio is 0.700. The % exhaust losses (1) diminish as the load increases; (2) diminish slightly as the ratio of gas to air increases; (3) increase as the speed increases; (4) diminish as the compression ratio increases. At full load the exhaust losses lay between 33.6% and 42.5%. The % heat lost by water-cooling of cylinder jackets (1) increases with the load; (2) diminishes as the ratio of air to gas increases; (3) diminishes as the speed increases; (4) and is sensibly independent of the compression ratio. A 6% increase in the temp. of the gases increases the amt. of heat lost by conduction and radiation (15%). The radiation loss (1) diminishes as the load increases; (2) increases as the ratio of air to gas increases; (3) diminishes as the speed increases; (4) increases slightly as the compression ratio increases. The % heat entering the exhaust valve jacket ranges from 8% to 12.5%, being greatest at low loads, low speeds, and with low compression ratios and rich mixts.

H. L. OLIN.

Second report of the joint committee in ventilation research. Institution of Gas Engineers and University of Leeds. ARTHUR SMITHELLS, et al. *J. Gas Lighting* 130, 573-579(1915).—These expts. were undertaken primarily to investigate the various influences affecting the flow of gases about burners where the main motive power is the heat of combustion of the gas, and to det. or confirm the laws of flow. The app. allowed for the burning of the gas under a flue in a chamber where conditions could be adjusted and factors measured with convenience and accuracy. On comparing a ring burner with a bunsen burner under similar conditions of gas consumption and of position with respect to the flues, it was found that the ring burner produced the greater

pressure-head. Whenever a burner is used in conjunction with a flue for ventilating purposes, there is a position at which the burner should be placed relative to the flue in order that (1) the products of combustion can pass directly into the flue, and (2) the max. use of the heat in the products of combustion can be made. Figures show only 2% difference between good inverted incandescent burners and upright ones. Providing no heat is lost from the ventilating system, the vol. of gases moving up a flue may be represented by the equation $V = vK/Ts$, where V = vol. at 0° and 760 mm. pressure, T = temp., K = calorific value of gas in kg. centigrade units per cu. ft. at 0° and 760 mm. pressure, s = mean sp. heat of products between 0° and T° in kg. centigrade units per degree per cu. ft. at 0° and 760 mm. pressure, and v = vol. in cu. ft. of gas burnt. In the specially constructed exptl. room, well insulated thermally and atmospherically and fitted with gas-fire and flue, by reducing the opening for the inlet of air the temp. increased until a certain small size of opening was reached, after which further reduction in the opening caused a decrease in the temp. within the flue and an accumulation of the products of combustion in the room, due to the failure of the gas-fire to turn all its products up the chimney. Increased ventilation was produced by enlarging the area of inlet, up to a certain low limit. The canopy and flue vent should be wide and simple, to offer as little resistance as possible to the flow of the flue gases. The tests showed that the ventilating capacity of gas fires is increased (with the same consumption of gas) by the provision of auxiliary openings at the back of the fires, care being taken that these openings be smaller than the flue vent lest there be a passing of products from the latter to the former.

B. W. GRIMES.

An important advance in gas producer efficiency. ANON. *Met. Chem. Eng.* 13, 399-400(1915).—The Morgan gas producer is based upon the principle that the best results are obtained by leaving the fuel bed undisturbed provided certain conditions are fulfilled. The coal should be properly spread and the surface properly leveled. The ash is removed without producing an uneven fuel bed and the coal is fed in small quantities regularly and continuously. These functions are performed by continuous mechanical means without hand labor. The mfrs. claim 50% increase in capacity combined with 20% advantage in quality of gas, over any other gas producers.

E. J. C.

Lynn producer-gas and ammonia recovery plant. ANON. *Engineering* 99, 624-6(1915).—In a general way the plant is based upon the Mond producer. It is automatically regulated and capable of using a large range of fuels. By-products can be profitably recovered in units as small as 500 h. p. The large bulky towers of the Mond system have been replaced by a novel system of vertical washers in which the gas is washed chiefly by its own momentum. The water seal in the grate allows the ashes to be removed without interfering with the working of the producer. The operation is automatically or manually performed. From the superheater the air and steam mixt. may pass through the jacket of the producer, through the grate and into the fuel. The saturator and absorber are of special design, consisting of a vertical cylinder chamber containing a series of truncated cones. Also in *Met. Chem. Eng.* 13, 456-8(1915).

C. A. COLE.

Charcoal filter for waste gases from the manufacture of ammonium sulfate. REINHARD. *J. Gasbel.* 58, 64(1915).—The gases are led through 2 vertical filters, each composed of an Fe pipe 14 in. diam. and 13 ft. long, packed with charcoal. The odor is almost entirely removed, so that no nuisance is caused by discharging the gases directly into the air in a crowded business district. About 75 kg. of charcoal are used for each filter, and after 6 weeks a regeneration by igniting the charcoal in a gas retort

restored its original efficiency with a loss of 20%. No direct figures are available for the vol. of gases purified; but during this 6 weeks period, 2500 cu. m. of crude NH_4OH were worked up. W. L. BADGER.

Gas producers with by-product recovery. ARTHUR H. LYNN. *Iron Coal Trades Rev.* 90, 743-5(1915).—A description of various types in use. H. L. OLIN.

The distillation of tar according to Kubierschky's patent. C. H. BOORMANN. *Essen. Chem. Ztg.* 39, 387-8, 422-4(1915).—Four cuts of the app. are shown and general directions for operating given. A statement of results and costs is included. Cf. C. A. 9, 1684. J. H. MOORE.

Coke briquets. BEHR. *J. Gasbel.* 58, 110-3(1915).—Coke breeze may be burned under boilers or in gas producers, or used for aggregate for concrete floors and partitions. The first requires special grates and blowers, and results in considerable loss of coke and frequent cleaning of flue-gas canals. The second gives entirely satisfactory thermal efficiency if the right type of producer is used; but local conditions often prevent this use. Cinders are serious competitors of coke for the third use. B. has operated a briquetting plant in connection with a gas plant for 6 yrs. at a good profit. The coke is less than 5 mm. in size and is mixed with 6% of hard pitch. The mixer is heated by steam at 350-400°, so that the pitch melts. The cylindrical briquets are 6 × 6 cm., stand handling while still hot, and find a ready market for domestic heating, especially in furnaces. Five % H_2O in the coke does not affect the quality of the briquets, and they are not harmed by exposure to the weather. They cost \$1.28 per ton to manuf. (allowing \$0.79 for the cost of the coke, which is too high as it cannot now find a market at any price) and sell for \$1.85 per ton. W. L. BADGER.

Heating experiments with gas coke and metallurgical coke in a hot water heating system. ORTO. *J. Gasbel.* 58, 166-9(1915).—The furnace was operated 3 days on each coke, 2 days only being used in the calcs. Weather conditions favored the metallurgical coke slightly; but the av. temp. rise was the same in both cases. The chimney losses were 8.5% with gas coke and 10.2% with metallurgical coke. This was due to the gas coke burning with less excess air because of its open structure. 1730 kg. of gas coke of 23% H_2O and 12800 B. t. u. air-dry, were burned against 1550 kg. of metallurgical coke of 2.5% H_2O and 12750 B. t. u. air-dry. The gas coke had been exposed to rain and snow, which was the reason for its high H_2O . The costs were \$6.30 and \$8.80 per ton, resp. This means a saving of 25% in favor of the gas coke; but if the abnormal H_2O content of the gas coke is considered, the saving becomes 40%. W. L. BADGER.

Determination of the specific gravity of gases (HOFSSÄSS) 1. Origin of coal (JEFFREY) 8. Photometry of vari-colored light sources (PIRANI) 2.

Brit., 3,886, Feb. 14, 1914. B. COCHRANE and R. PREL. A vertical coking-retort, carbonizing chamber, or the like, is provided with an inner cylinder imperforate except at the base, wherein are arranged a number of smaller tubes, which are in communication at the top with a suction main, and at the bottom open into, or are connected by, tubes to the space containing the coal, etc., to be carbonized. The inner cylinder may be partly or wholly filled around the smaller tubes therein with heat-retaining material, such as broken firebrick. The carbonizing chamber is heated by flames from

gas nozzles preferably arranged tangentially to the chamber and at the center and bottom thereof. Gas nozzles may also be arranged for heating the material within the inner cylinder, the upper part of the cylinder being in that case connected to a flue by pipes.

Brit., 3,888, Feb. 14, 1914. M. A. ADAM and WETCARBONIZING, LTD. Electro-osmosis under pressure is employed to assist the further removal of water liberated in peat by a heat-treatment, such as wet-carbonization, and partly removed by filter-pressing or otherwise. Elec. current, at a pressure of about 50 v. and a c. d. of some 50 amps. to the sq. ft., is passed through lukewarm peat in a space the vol. of which is decreased gradually so as to maintain a pressure of, say, 250 lbs. to the sq. in. Preferably, for this purpose, a filter-press is employed, with collapsible chambers in which the H_2O content of the peat is first reduced to, say, 68% under a fluid pressure of some 100 lbs. to the sq. in., whereupon the chambers are squeezed, and current is applied until the H_2O content is reduced to, say, 55%, leaving material fit for use in a gas producer. The peat may have been heated with or without acids or metallic compds., and may be dealt with subsequently according to the methods of 17,610, 1911 (C. A. 7, 411) or 25,146, 1912 (C. A. 8, 1498). Specifications 10,834, 1903, 4684, 1911 (C. A. 6, 2309) and 17,427, 1912 (C. A. 8, 416) are referred to also.

Brit., 3,899, Feb. 14, 1914. B. O. JENKINS. A fuel for internal-combustion engines is obtained by distg. at $80-160^\circ$ a mixt. of EtOH or other volatile alc. with benzole naphtha, or other distillate of coal tar or from coke ovens, and about 1% of camphor.

Brit., 4,120, Feb. 17, 1914. E. L. KNOEDLER. Incandescent mantles are shaped and hardened in 1 operation by directing a hardening flame into a mantle placed in a mold or muffle, which is such that a thin film of hot gases is maintained between the mantle and the mold. The mold is a perforated tube of Pt, ceramic material, or other refractory material, and may be open or closed at its lower end. Cf. C. A. 9, 522.

Brit., 4,242, Feb. 18, 1914. BERLIN ANHALTISCHE MASCHINENBAU AKT.-GES. Gas liquor has a part of its volatile NH_4 compds. driven off in an evapg. vessel at the top of a retort setting, the remainder being driven off by strong heating of the liquor in a second vessel. The liquor from this second vessel passing through a coil gives up its heat to an acid bath into which the volatile NH_4 compds. are passed, and is then conducted into a vat below the grate of the retort furnace. The cold liquor is fed to a jacket surrounding a condenser in which NH_4 compds. from the evapg. vessel collect, and flows into the evapg. vessel from which it passes into a second evaporator heated by a gas burner. The NH_4 compds. from the second evaporator pass by a bent pipe into the acid bath in a saturator from which noxious gases escape by a flue.

Brit., 4,757, Feb. 24, 1914. T. H. PETERS, G. L. and C. P. TUXFORD. A composition fuel consists of a mixt. of 1 cwt. of portland cement, 5 lbs. of ocher, and 5 oz. of $KMnO_4$ with 1 ton of small coal, coke, or peat, the whole being damped and molded.

Ger., 281,472, Oct. 9, 1913. MASCHINENBAU-ANSTALT HUMBOLDT. **Utilizing brown coal filter slimes**. In the manuf. of brown coal briquets the drying of the ground material gives rise to a fine highly explosive brown coal dust which is sepd. by means of a series of filters in the wet way and then partly freed from H_2O (up to 50-60%). Attempts have been made heretofore to utilize this slime, especially as a fuel for boiler firing, but this is not practicable on a large scale. The drying was attended by serious difficulties. By this process the filter slime is mixed with dry powdered clay by a screw mixer or in a centrifuge, and compressed to briquets.

Ger., 282,355, Mar. 6, 1914. A. HECKERT. **Process and retort for the dry distillation of coal or the like**, with the addition of steam which is first superheated and then decomposed, the products of decomp. being conducted to the coal. The superheating, decomp., and the action of the decomp. products on the coal being gasified are effected in sequence within the retort, incandescent graphite being employed as the decomposing agent. A suitable app. is specified.

Ger., 282,356, Jan. 6, 1914. G. L. WILKINSON. An **absorbent for acetylene solutions**, used in lieu of the filling, such as alk.-earths, coke, powdered stone, cement, pumice, asbestos, cotton, used heretofore. The new mass consists of silk or silk waste, the fibers of which have the property of absorbing acetone, crude acetone, or any other solvent for acetylene. This material can be packed much more densely in the containers than has been possible heretofore. The silk expands as it takes up the solvent, filling the container and leaving no pockets for the accumulation of the liquids. The silk material is forced into the container under pressure. A definite amt. of solvent is then introduced. As soon as this has been completely absorbed by the silk, the purified acetylene gas is forced into the packing material and is absorbed by the solvent. Cf. C. A. 9, 371.

Origin of naphtha. N. KIZHNER. *J. Russ. Phys. Chem. Soc.* 46, 1428-41 (1914).

—A new hypothesis of the origin of naphtha. It is based upon Forquignon's expts. (*Ann. chim. phys.* [5], 23, 516), which showed that when H is passed over red hot cast iron the C in the latter is converted into hydrocarbons, while the traces of S, P and As are changed to org. compds. of these elements. These expts. also showed that the passage of N over red hot cast iron yields (CN)₂. The hypothesis assumes that naphtha owes its origin to the interaction of the H with the C, both of which are held in soln. by the Fe existing in the bowels of the earth. This interaction began when in the process of cooling, the earth reached the state of a red star. The difficultly fusible Fe and C liquefied and solidified first, and owing to its high sp. gr., the Fe, holding in soln. the H, settled at the lower strata of the globe. Owing to the high temp. prevailing in the depths of the earth, the reaction between the H and the C has been going on for ages and doubtless is going on now. The comparatively low sp. gr. of the hydrocarbons causes them to rise as naphtha to the surface, passing through various strata which modify its character. The cyclic hydrocarbons of naphtha owe their formation to the high temp. and pressure prevailing in the innermost strata. As to the optical activity of naphtha, it is due to the influence of terrestrial magnetism on the different degrees of reactivity (decomp., condensation, oxidation, etc.) of optical antipodes, it being assumed that these differ in reactivity to such a slight extent that the difference escapes our observation. Hence in the usual reactions racemic compds. are formed. But the magnetism of the earth enhancing the reactivity of both antipodes and acting through geologic ages, may favor the reactivity of one of them, changing it to other substances, and thus permitting the other antipode to impart activity to the naphtha.

H. M. GORDIN.

The Rittman gasoline process. W. F. RITTMAN. *Nat. Petroleum News* [1] 7, 2-4 (1915).—Vaporized petroleum is passed into a hot tube at 450°, the pressure being 90-500 lbs. per sq. in. The vapors are condensed under pressure and the condensate distd. for its gasoline content. The residue may be revaporized and passed through the tube. By using the oil in the form of vapor any combination of temp. and pressure may be applied, and in the case of fire only a small amt. of oil is exposed. Any oil from kerosene up may be used and it is claimed that by reason of the reaction being gaseous instead of liquid, the C deposited is so small as to be negligible.

A. J. PHILLIPS.

The McAfee gasoline process. M. MCAFEE. *Nat. Petroleum News* [2] 7, 20-5 (1915).—Petroleum oils are heated with 3-10% of AlCl₃ in ordinary stills, molecular rearrangement taking place and lighter oils being formed. Temps. of 260-315° are used and no pressure. Some test runs showed the gasoline content of Texas asphaltic crude to be 24%, Mex. crude 10%, Caddo 26% and reduced Oklahoma oil 20%. The light distillates require no treatment with acid and about 1/3 of the original oil is left in the still; this is treated with H₂SO₄ and worked up into lubricating oil. Most of the AlCl₃ remains as a coke residue from which the AlCl₃ is regenerated. *Cf. C. A.* 9, 860.

A. J. PHILLIPS.

Motor cylinder lubrication. G. S. BRYAN. *J. Am. Soc. Mech. Eng.* 37, 293-4 (1915).—Under the intense heat of the cylinder motor oil may volatilize without decompn., may decompose with formation of free C and H, in which case most of the C will be blown out of the exhaust as a fine dust, or the oil may decompose with formation of other hydrocarbons of a different nature, in which case C deposits will form a gummy,

sticky layer. Oils from southern asphalt base crudes have shown less C-forming proclivities in the cylinder than oils from paraffin base Penn. oils. The asphaltic oils are mostly of the ethylene and naphthene series and as compared with the paraffin series they tend to distill without decompn. Sp. gr. detns. are without value to the consumer.

The recovery of benzine from synthetic crude oil. WALTER O. SNELLING. *Pittsburg. Chem. Ztg.* 39, 359-60(1915).—A general statement of his results. Cf. *C. A.* 9, 1388, 1841.

J. H. MOORE.

Nature and classification of paraffins and their extraction from naphtha. M. A. RAKUZIN. *J. Russ. Phys. Chem. Soc.* 46, 1544-66(1914).—The primary object of the investigation was to obtain a naphtha that does not congeal readily and that is free from paraffins. In the course of the work numerous other problems were met with and were investigated. The results may be summarized as follows: The higher, so-called hard paraffins are removable from naphtha by centrifugalization. In absence of excessive pressure the Chamberlain-Pasteur filter absorbs both tar and paraffin, while the material of this filter in powdered form absorbs chiefly paraffin. The filtration of naphtha through this filter in candle form is 4 times faster than through a disk made of its powdered material, but to exercise its full efficiency the candle must be completely immersed in the liquid to be filtered. Kaolin and Al_2O_3 also absorb both tar and paraffin. Floridin (hydrated $AlMg$ silicate) has both decolorizing and tar- and paraffin-absorbing properties, but the paraffins absorbed by it are chiefly the soft ones, m. about 50° . Successive centrifugalization and treatment with floridin still leaves in naphtha about 1.7% of paraffin which cannot be extd. in the cold. The naphtha paraffins may be classified into such as are removable by centrifugalization (hard paraffins, m. 69°), such as are removable by digestion with floridin (soft, m. 50°) and paraffins removable by distn. (m. 59°). Owing to the strong tendency of naphtha to supercooling, there is no exact relation between its congealing p. and its paraffin content. The opinion that some of the naphtha paraffins (proto- and pyro-paraffins) are amorphous, becoming cryst. only during the distn., is erroneous. This is proved by the fact that the paraffins extd. in the cold (by centrifugalization or floridin) are cryst. Even after removal of the hard and the soft paraffins naphtha still shows cryst. structure when examd. optically.

C. E. MUNROE.

The system "nitroglycerin-guncotton." Condensation of nitroglycerin vapor on guncotton in vacuo at constant temperature. D. CHIARAVIGLIO AND O. M. CORBINO.

Rome. *Atti accad. Lincei* 24, I, 247-50(1915).—The gelatinization of guncotton, which is so important in the manuf. of explosives, is usually accomplished by means of a volatile non-explosive solvent or by means of some other substance which is usually explosive but little volatile and which is retained in the final product as an essential constituent. Of these nitroglycerin is especially important. Such mixts. of nitroglycerin and guncotton are considered to be colloidal but their structures, degree of homogeneity, etc. are not known (cf. Paterno, Traetta-Mosca, *Gazz. chim. ital.* 38, II, 512; cf. *C. A.* 4, 1808). C. and C. placed a layer of powdery nitrated guncotton in the bottom of a large flask, in the center of which a beaker containing nitroglycerin was placed. The flask, was attached to the app. previously described (*C. A.* 8, 2061). The whole was evacuated with a Hg-vacuum pump and kept in a large air thermostat at a const. temp. of 30°. The nitroglycerin was gradually evapd. from the beaker at a rate which diminished until after some days it was imperceptible. At the end of the expt. the guncotton is apparently not much changed except that it is a little more sticky. But at high pressures it is converted into a homogeneous, transparent, gelatinous mass having the appearance of ordinary ballistite. When the expt. was conducted at 30° a colloidum cotton (12.25% N) took up 31.5% nitroglycerin in 7 days and 35.6% in 40 days. A guncotton (13.27% N) took up 37.4% nitroglycerin in 40 days. In a somewhat complicated glass app. (not described) nitroglycerin and guncotton were brought together and a marked increase in temp. was observed, so that the process observed is not simply the soln. of a solid in a liquid. There is thus a true exothermic chem. reaction between the guncotton and the nitroglycerin or else all the facts must be ascribed to simple imbibition phenomena Cf. following abstr. E. J. WITZEMANN.

The system "nitroglycerin-guncotton." Extraction of nitroglycerin from ballistite by distillation in vacuo at ordinary temperature. D. CHIARAVIGLIO AND O. M. CORBINO. Rome. *Atti accad. Lincei* 24, I, 361-6(1915).—The app. described in the preceding abstract is illustrated. A layer of ballistite scales (0.04 mm.) was placed in a large flask and by suspending the empty beaker under a condenser fitted in the flask the volatilized nitroglycerin was condensed and dropped into the beaker. At a pressure of 0.001 mm. the nitroglycerin distills into the beaker at room temp. which was only slightly higher than that of the condenser water. At 32° the nitroglycerin content of ballistite was reduced in 11 days from 48% to 32% and at 40° from 51% to 20.4% by distg. off the nitroglycerin in this way. The distn. gradually becomes slower and comes to equil. at a point depending on the temp. The system "nitroglycerin-guncotton" thus behaves exactly like the system " H_2O -cellulose" in this respect. The ballistite does not show any external change even under the microscope as a result of the treatment. The nitroglycerin distd. off is colorless and shows its normal stability in the Abel test except in one case in which a deteriorated specimen of ballistite was used and in which the nitroglycerin distillate was distinctly yellow and decomposed spontaneously in a few days. The expts. are of practical interest since they make it possible to remove nitroglycerin from explosives which contain too much without raising the temp., and since they simplify the examn. of explosives of the ballistite type as to stability. In the distn. described above gaseous products are also formed, the examn. of which may prove to be of importance in the study of the slow decompn. of these explosives.

E. J. WITZEMANN.

An instrument for recording pressure variations due to explosions in tubes. J. D. MORGAN. *Proc. Phys. Soc. London* 26, 172-7(1914). PAUL D. FOOTE.

Chemical engineering in nitrocellulose manufacture. S. L. STADELMAN. *Met. Chem. Eng.* 13, 361-6(1915).—S. gives a detailed description of methods for producing cellulose nitrates for guncotton, pyrocellulose powder (propellant), and gelatin dyna-

mite (coagulant). An endeavor has been made to record from practice results such as are not given in text books or in the periodical literature and the article shows that the author has largely realized this ideal.

CHARLES E. MUNROE.

Rules for handling, storing, delivering and shipping explosives. Institute of Makers of Explosives, U. S. A. *Pamphlet No. 5, 1914.*—The object is to place in convenient form such rules as experience in the explosives business has taught to be necessary to guard against accidents from these substances, combined with the official regulations of the I. C. C.

CHARLES E. MUNROE.

Standard storage magazines. Institute of Makers of Explosives, U. S. A. *Pamphlet No. 1, 1914.*—Five types are described: (a) Medium soft brick laid in cement mortar containing 15–25% of CaO. (b) Wooden magazines sheathed outside and lined inside with boards, the intervening space being filled with weak cement mortar. (c) Standard types of portable steel magazines bullet-proofed with weak cement mortar. (d) Box magazines for small quantities of explosives for immediate use or distribution. (f) Balloon construction. The text is accompanied by 11 sheets of detailed scale drawings.

CHARLES E. MUNROE.

American table of distances. RALPH ASHETON AND EDMUND B. COY. Institute of Makers of Explosives, U. S. A. *Pamphlet No. 2, 1914.*—A table is given specifying the distances to be maintained between storage magazines (for quantities of explosives varying from 50 to 500,000 lbs.) and inhabited buildings, public railways and public highways. The conclusions have been reached by a study of the data available from the records of explosions occurring during the last 50 years, and significant data for 179 such explosions, involving quantities varying from 200 to 875,000 lbs. and 12 different kinds of explosives, are presented in tabular form and plotted into a chart. An interesting table shows the distances from the sites of explosions of persons who escaped uninjured, as for example the 2 men in a buggy but 1,000 feet away from the explosion of 398,415 pounds of dynamite and black powder at Highland, Cal.

CHARLES E. MUNROE.

Explosion in nitroglycerin final washing house. A. COOPER-KEY. *Home Office Rept. 215, 5 pp. (1915).*—The material which exploded was "cordite paste" (for use in making cordite M. D.), consisting of a mixt. of 51 lbs. of guncotton and 21 lbs. of nitroglycerin. It had been placed, for transportation to the incorporating house, in bags made of "rubber insertion" (canvas impregnated with rubber). Cordite paste is declared to be "a mixt. which in dustiness is only comparable to dry guncotton fluff" and it was customary therefore, after filling and tying the bags, to brush the dust off of the outsides before loading them on the bogie, and further, to diminish the likelihood of accident; these bags were dusted off with the hand directly. Because no other source of ignition could be detected, and because the accident occurred on a "fine, dry, cold morning" and the "men in the building were wearing stout rubber overshoes" a static elec. charge from one of them is believed to have caused the explosion. (In this connection see "Are not dynamite catastrophes intimately associated with electric phenomena?" L. J. Le Conte. *Trans. Technical Soc. Pacific Coast* 2, 223. (1885). In view of the war emergencies Major Cooper-Key advises carrying out all operations from nitration to filtration in a single building. Expert witnesses should take special note of a suggestion such as this.

CHARLES E. MUNROE.

J. H. MOORE.

Use of sodium perborate. E. TREPKA. *Rev. gén. mat. color.* 18, 193(1914); *J. Soc. Dyers Colorists* 30, 302.—For clearing whites in cotton material dyed with logwood black, Na perborate may be used where bleaching powder would only turn the shade to brown. Pad the goods with a soln. contg. 3-5 g. Na perborate per l. and dry on drums. Chrome dyes are rapidly altered by this treatment, whereas sulfide and vat dyes are brightened. The action of the perborate may be increased by the addition of alk. substances, but the solns. then tend to decompose very rapidly. Na₂HPO₄ (1-2 g. per l.) may be added.

MILES R. MOFFATT.

Notes on kapok. ANON. *J. Soc. Chem. Ind.* 34, 524(1915).—The best quality of kapok (*Bombax malabaricum*) from Java is used in life-saving jackets, having a much higher sustaining power than the inferior qualities. The inferior qualities are apt to be adulterated with waste cotton, etc. Cotton is stained more deeply by I than kapok. Kapok is beginning to take the place of eider-down. Vermin will not go near it. It is of no use for weaving or spinning. It is often adulterated with *Calotropis procera*, which is useless. By the Cross and Bevan method cotton has about 95% of resistant cellulose, kapok only about 50%. Kapok has been nitrated

and guncotton made from it, but the nitrocellulose is probably not stable. Cellulose can be obtained from it in large quantities. An inferior kind of kapok is produced from a creeper in W. Africa; the pods are nearly the size of a cocoa pod and each contains a large amt. of fiber. The vine yields a little rubber. It has been suggested that the cars of balloons be lined with this material. The H_2O -repellent power is in inverse proportion to the quality of the fiber. The yellowest varieties are the best for the purpose. They could be immersed in H_2O for 1 or 2 weeks without the H_2O penetrating them. The fiber is very brittle. If grown in large quantities, it might be used as a source of cellulose for paper, and similar purposes, as it is cheaper to grow than cotton; but it would first be necessary to ext. the resinous matter (which repels H_2O), a kind of wax readily extd. and for which com. uses might be found. F. W. S.

Stability of hypochlorite solutions (GRIFFIN) 18.

Brit., 3,796, Feb. 13, 1914. BAYER & CO. Azo dyes are obtained by combining diazo, diazoazo, or tetrazo compds., or the intermediate products from 1 mol. of a tetrazo compd., and 1 mol. of an azo dye component, with the products formed by condensing 2-naphthol-1-carboxylic-6-sulfonyl chloride with phenols, naphthols, amines, aminophenols, aminonaphthols, or their carboxylic, sulfonic, etc., derivs., and splitting off the carboxyl group if desired. If the carboxyl group is not previously removed, it splits off during the formation of the azo dye.

Brit., 4,668, Feb. 23, 1914. E. GIRZIK. Dyeing artificial leather consisting of fabric coated with cellulose compds., such as celluloid or nitrocellulose, by mixing the celluloid or like soln. with substances which readily form lakes with aniline dyes, *e. g.*, $Al(OH)_3$, Al acetate, or silicate, applying the mixt. to the fabric, drying, and dyeing with suitable dyes so as to dye both the fabric and the celluloid or like layer. In an example, a cotton fabric is coated with a soln. of nitrocellulose in alc., acetone, etc., mixed with softening agents and $Al(OH)_3$, dried, and dyed with basic dyes in an acid bath.

Brit., 4,827, Feb. 24, 1914. P. SCHILDE. Moistening yarns and the like by exposing the material repeatedly and alternately to cold and warm currents of moist air, either in different chambers or in the same chamber, and always removing the material in the cold state after treatment with the cold current of moist air.

Fr., 468,525, Apr. 25, 1913. R. VIDAL. In a process of dyeing skins and animal fibers, the known property of dichromate of protecting the material from the destructive action of the alkali sulfides is taken advantage of in dyeing the hair of the skin independently of the leather, by treating the chromed skin in a bath of Na_2S , chromogen vidal black (1 mol. *p*-phenylenediamine + 2 mols. phenol). If the leather is to be dyed also (say a blue), S-dyes are used in conjunction with the above. Cf. C. A. 8, 2638.

Ger., 280,973, June 20, 1913. L. GIVAUDAN and A. KAUFMANN. Mfg. 2-cyanoquinoline and 1-cyanoisoquinoline by treating 1-benzoyl-2-cyano-1,2-dihydroquinoline or 2-benzoyl-1-cyano-1,2-dihydroisoquinoline with PCl_5 , SOCl_2 , or SO_2Cl_2 , in the presence of anhydrous indifferent diluents.

Ger., 281,304, Dec. 28, 1913. E. GIRZIK. Dyeing artificial leather. See Brit. 4,668 (*supra*).

Ger., 281,352, Dec. 21, 1913. AKT.-GES. FÜR ANILIN-FABRIKATION. Dyeing skins, hair, and the like, mordanted or unmordanted, in the presence of a suitable oxidizing agent, such as H_2O_2 , in a bath which contains a salt of a base of the following comp. or of a deriv. of such a base. $\text{Me}_2\text{NC}_6\text{H}_4\text{NHC}_6\text{H}_4\text{R}$; $\text{R} = \text{NH}_2$, NMe_3 , NEt_3 , or OH . Cf. C. A. 9, 386.

Ger., 281,422, Nov. 22, 1912. BAYER & CO. Mfg. color lakes. The lakes obtained from purpurin carboxylic acid excel those obtained from purpurin and alizarin in fastness to light and purity of tone. Lakes can now be obtained from purpurin-3-sulfonic acid which have properties similar to those from purpurin carboxylic acid, by converting them into Al lakes. These lakes are very fast to light, and have a clear eosin-like shade. E. g., 100 kg. $\text{Al}_2(\text{SO}_4)_3$ (18% Al_2O_3), and 1.25 kg. purpurinsulfonic acid (1,2,4-trihydroxyanthraquinone-3-sulfonic acid) as the NH_4 salt, are dissolved, with warming, in 1000 l. H_2O , and pptd. with a soln. of 30 kg. calcined soda in 300 l. H_2O . Or, 1.25 kg. purpurinsulfonic acid (Na salt) are dissolved in H_2O and boiled up with 60 kg. $\text{Al}(\text{OH})_3$ (10%). Cf. C. A. 9, 156.

Ger., 281,423, Nov. 19, 1912. Addition to 250,387 (C. A. 7, 265). E. HAGEN. Mfg. color lakes from vegetable materials containing the dye as the glucoside. The product obtained according to the principal process can be obtained also by breaking the glucoside down by enzyme or by heating with dil. acids, as H_2SO_4 , or by means of ferments, whereby the dyes of the glucosides (rhamnetin, quercetin, fisetin, etc.) form, but are not applicable as such for dyeing on account of their low dyeing powers. These dyes do not yield satisfactory dyes with alk. earth or metal salt solns., at the room temp., but upon heating the free dyes with alk. earth or metal salt solns., color lakes of brilliant shades are formed, which are stabilized to organic acids by treatment with inorganic salts of the category specified. E. g., the initial material containing the glucoside, such as buck-thorn berries, quercitron, and the like, is heated, in a comminuted state, with dil. H_2SO_4 , or acted upon with ferments, whereby the glucosides break down and yield the free dyes which are sepd. from the fibrous material by sifting, or otherwise. The resulting dyes are boiled with solns. of alum, $\text{Al}_2(\text{SO}_4)_3$, MgSO_4 , or the like, to obtain the corresponding color lake. By the direct action of organic Al salts and $\text{Al}(\text{OH})_3$ on color glucosides, color lakes are formed but they are not stable to organic acids.

Ger., 281,449, May 14, 1913. FARBW. V. M. L. & B. Mfg. disazo dyes by coupling the tetraazo compd. of urea, *p*-aminophenylurea-*p*-aminophenyldisulfonic acid, with 2 like or unlike azo components. Cf. C. A. 9, 156.

Ger., 281,490, Jan. 29, 1914. F. ULLMANN. Separating 1-nitroanthraquinone from crude nitroanthraquinone by fractionating *in vacuo*, the dinitro products remaining as a residue. The pure product goes over at 7 mm. and 270-271°, without decompn.

Ger., 281,520-21, Mar. 21, 1913. Addition to 263,382 (C. A. 8, 257). FARBW.

v. M. L. & B. Vat dyes, resembling those obtained by 265,195 (C. A. 8, 429), by allowing H_2S to act upon halogen quinone arylides, with the employment of diluents. The operation is carried on in closed vessels under pressure in order to prevent loss of H_2S . According to 281,521, halogen quinone arylides are treated with S and a halogen-acid-binding agent.

Ger., 281,859, Jan. 10, 1912. BADISCHE. Obtaining fast color prints by printing with the Cr compds. of hydroxyanthraquinonesulfonic acids, or their derivs., specified in 280,505 (C. A. 9, 1998) and then steaming. E. g., a printing color is obtained from 200 g. of a soln. (obtained according to 280,505) 700 g. HOAc-starch-tragacanth thickening, and 300 g. H_2O . The print is steamed for 5 mins. in the mather-plate, rinsed in H_2O , and finished in the usual manner. The dye is fixed in the form of a blue-green lake very fast to washing and light.

Ger., 282,351, Jan. 3, 1914. H. GIESLER. In a process of producing designs on fabrics of all kinds, by carbonization, the warp or woof, or both, are incorporated with threads which have been treated with an acid or salt soln. which destroys vegetable fiber at a high temp. After applying an agent which to an extent renders the acid or salt inactive, the fabric is heated to a temp. sufficient for carbonization. E. g., into a voile of cotton yarn is worked a second warp of cotton threads which have been treated with 7° $AlCl_3$ soln. Upon this fabric a design is then printed with a soda soln. which is sufficiently strong to neutralize the action of the $AlCl_3$ at the points of contact. The fabric is then placed in a heating chamber and exposed to a temp. which carbonizes the prepared fabric. Finally, the combustion residues are removed by blocking, brushing, or milling. The resulting fabric has a voile ground upon which appears a strongly marked design which has the appearance of embroidery.

Ital., 129,784; 394-173, Feb. 5, 1913. I. GUARESCHI. In a process of dyeing wool, silk, cotton, etc., with the use of a new deriv. of triphenylmethane, the material is dyed with fuchsin in shades varying from rose to sky-blue, then fixed by bromination.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

White paint. Inland Rev. Dept., Canada Bull. 301(1915).—Report of exam. of 116 samples of white paint collected throughout Canada. Analyses of the pigments showed that 28 samples were essentially white lead, 30 samples essentially ZnO or ZnS , 9 mixts. of Pb and Zn, 14 Pb and Zn with $BaSO_4$, and 35 chiefly $BaSO_4$.

E. W. BOUGHTON.

A study of some curious painting phenomena. H. A. GARDNER. J. Frank. Inst. 179, 681-95(1915).—*Mildew and its prevention*: A description of mildew on painted surfaces in New Orleans is given. The dark scrapings from the mildewed surfaces were added to a culture medium of cypress wood decoction and agar, and pure cultures subsequently obtained. The two principal types of fungi which developed were species of *Aspergillus* and *Penicillium*. The former was found to be the more hardy. Expts. showed that the development of fungi was much more rapid on paint coatings which were soft and subject to the retention of moisture. Paints prepared with a pigment containing 25-50% of ZnO gave films that were resistant to fungus growth. It is possible that the fungus spores are introduced into the wood during the soaking process at the lumber mill. Treatment of the wood with $ZnCl_2$ soln. previous to painting is recommended. *Washing of paint caused by inferior oil*: The failure of paint coatings due to saponification or "washing" may be caused by the use of oil

which contains moisture and "foots." Growths of mold, a species of *Fusarium*, were obtained from linseed oil "foots." The microorganisms in the foots may have a fat-splitting action with the formation of fatty acids and glycerol, thus causing softening of the coat. Both Pb and Zn paints may exhibit this "washing." "*Rusting*" or *brown spotting*: The formation of brown spots on paint coatings is apparently due to 2 causes, one being the leaching out of sol. matter in the wood by moisture. Such sol. matter is brought to the surface and forms compds. with the Pb and Zn in the paint. As brown spotting occurs on repainting jobs on old wood, a second cause may be an enzymic fat-splitting action, as mentioned above, with subsequent formation of Pb and Zn compds. of various fatty acids. *Conclusion*: "From previous consideration it is apparent that many painting defects may be prevented through the use of paints of the composite class, based upon white lead pigments but containing sufficient zinc oxide to present a firm, hard film. When paste paints are thinned by the painter, only clarified, well settled, moisture-free linseed oil should be used. E. W. BOUGHTON.

Investigations of iron tannate inks. XIII. The influence of the condition of the air and temperature of the working space upon the result of the "keeping quality" test. F. W. HINRICHSSEN AND R. KEMPF. *Mitt. kgl. Materialprüfungsamt.* 32, 536-8 (1914); through *Chem. Zentr.* 1915, I, 809-10.—The new regulations for official ink testing give directions for making the test for keeping quality in glass (C. A. 7, 2482). Expts. made according to these directions show that HCl and especially NH₃ vapors in somewhat concd. form as well as SO₂ vapor exercise a strong influence on the keeping quality test of Fe tannate inks. In the diln. in which the acid and basic vapors, H₂S, etc., occur in the chem. lab. and the relatively short time of the test, their influence appears to be negligible. However, the space used for the test should be kept as free as possible from HCl, SO₂, and NH₃. Cf. C. A. 8, 2069. E. W. SMITHER.

The composition, properties and testing of printing inks. Bur. of Standards. *Circ.* 53(1915); cf. C. A. 8, 3632.—This circular contains a general discussion of the subject under the following captions: Historical; comp. of printing inks; ink manuf.; relation of the ink to the paper; opacity of inks; necessity for proper grades of paper; what constitutes a good ink; analysis of printing inks; relation of lab. tests to tests under working conditions; manuf. and testing of linseed oil; bibliography.

Detection of manganese in lacquers and driers (SACHER) 7.

Brit., 29,524, Dec. 22, 1913. G. PATERNO and C. MANUELLI. HF, fluorides, fluosilicates, and fluoride compds. other than chromyl fluoride and its compds. are used in submarine varnishes for destroying algae, molluscs, etc. Cf. C. A. 9, 1552.

Brit., 3,573, Feb. 11, 1914. R. STRAUSS. Furniture polish. See Ger., 279,127 (C. A. 9, 1127).

Brit., 4,113, Feb. 17, 1914. M. BRENNEISEN. A weatherproof paint is manufd. by mixing Zn powder with linseed oil varnish to a dough-like mass, stirring in HCl, and dilg. with linseed oil varnish or the like. An example mentions linseed oil varnish 140 g., Zn dust 1 kg., strong HCl 180 g., and for diln., linseed oil varnish 320 g., and turpentine 100 g.

Brit., 4,419, Feb. 20, 1914. M. WOLFF. A basis for printing ink consists of

finely powdered mineral substances, of white, gray, or yellow color, and of a nature compatible with resin oil, crude petroleum or petroleum distillates, vegetable or carbon black, and aniline dyes, *e. g.*, diatomaceous earth or the like. The substances are mixed with the other ingredients without the application of heat or pressure and without intercedent drying. Barytes may be used. Cf. *C. A.* 8, 2072.

Can., 160,682, Feb. 16, 1915. L. V. REDMAN. The fusible anhydrous phenolic condensation product produced by direct reaction substantially in the absence of water between an anhydrous methylene compd. and a phenolic compd. in the proportions of 1 reacting weight of the methylene compd. to more than 5 reacting weights of the phenolic compd.

Can., 160,683, Feb. 16, 1915. L. V. REDMAN. In producing a phenolic condensation product, a phenolic compd. is mixed with a methylene compd. in the proportions of more than 1 phenol group to each active methylene group, and the mixt. is subjected to the action of heat substantially in the absence of water and causing an anhydrous reaction, to produce a fusible phenolic resin.

Fr., 468,598, Feb. 18, 1913. M. BRENNERSEN. In mfg. a weatherproofing paint (anti-rust compn.), Zn dust is kneaded up with linseed oil varnish, the mass is combined with HCl, the H₂O is decanted, and the product dild. with linseed oil varnish and turpentine.

Ger., 281,615, Apr. 30, 1913. C. JAEK. Mfg. colored linoleum, wax cloth, lin-crusta, and the like, bearing ornamental designs.

Ger., 281,687, July 4, 1913. CHEM. FABRIK GRIESHEIM-ELEKTRON. Mfg. technically valuable products from organic vinyl esters. By the polymerization of organic vinyl esters, alone or in admixt. with each other, products of value are obtained which, according to the initial material and the conditions of treatment, exhibit different properties. *E. g.*, by acting with chem. rays on vinyl esters (vinyl acetate or vinyl chloracetate) solid masses are obtained directly in a colorless, clear state which, by virtue of their exceptional properties, are applicable directly, and serve as a substitute for celluloid and like substances. The polymerization of the vinyl ester can be effected also by heating. If the polymerization is effected in a suitable form, the shaped article is obtained. However, the product may be shaped by softening and allowing to cool, or by dissolving and evapg. off the solvent. The softened mass permits of easy working. Foreign substances may be mixed with the mass. It may be sawed, cut, filed, and otherwise handled. By coating with acetone, epichlorohydrin, or other solvent the material may be polished and cemented together. Varnishes are obtained by soln. in suitable solvents. It is fireproof and odorless. Cf. *C. A.* 9, 149, 351.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Physico-chemical investigation of rape oil. P. A. MEERBURG. *Chem. Weekblad* 11, 1111-4 (1914).—The main physical detns. of rape oil are: Sp. gr., refractive index, congealing point and viscosity. M. estd. the critical congealing temp. of rape oil in 100 samples by mixing with aniline. In rape oil, as outlined graphically, it reaches its high mark at 37.6° in 80% aniline; adulteration of oil by sesame, linseed or cottonseed oil is indicated by obtaining figures outside of limits detd. The method is rapid and can be carried out with ordinary app.

28. SUGAR, STARCH AND GUMS.

A. H. BRYAN.

Production and refining of sugar in England. ANON. *J. Soc. Chem. Ind.* 34, 316-20 (1915).—Discussion by the London Section of the Soc. of Chem. Ind. on the production of sugar within the Empire. The British Empire consumes \$100,000,000 worth of sugar annually, 80% of which has been produced on the Continent. With this main supply not only cut off but largely destroyed they must look elsewhere for their sugar. Sugar beets have been successfully raised in the British Isles as well as in many of the Colonies. Expts. have shown that a good yield of fair quality may be secured under such conditions as would make the undertaking profitable. It was suggested that a preferential duty be placed upon sugar until the industry should be firmly established. H. R. SMITH.

The rise in purity of cane juice during clarification. H. C. PRINSEN-GEERLIGS. *Louisiana Planter* 54, 284-5 (1915).—The presence of salts or occluded air will affect the Brix readings so that the quotient of purity calcd. with such figures as a basis would be much too high. Suspended muddy matter as an accidental admixt. in the raw juice

will also affect the degrees Brix so that after clarification, when the mud has been carried over in the scums, the readings are not further affected. In deciding the merits or defects of a clarification scheme, the quotient should be found by drying the filtered juice for the detn. of the dry matter and the sucrose should be detd. by double polarization.

A. GROSS.

Sugar recovery from beet molasses by the use of strontia. DAUDE. *Z. Ver. Zuckerind.* 65, 139-64(1915).—A review, with many drawings. W. L. BADGER.

Determination of sucrose in beets after freezing and thawing. E. SAILLARD. *Compt. rend.* 160, 360-3(1915).—Beets stored in piles and subjected to freezing and thawing gave off an odor of alc. At one or more points on the surface of the beets the gas and also a gummy material collected in drops. The juice from these beets was ten times as acid as that from normal beets. This acidity increased on standing; at the same time the viscosity of the juice decreased, due to the hydrolysis of some of the gum to acid. In the sugar mill at first carbonation the juice deposited a viscous coating over the filter press, making filtration difficult. The filtered juice was more highly colored than usual. Five samples of beets which had been frozen and thawed, which, when dug, showed 15-16% sucrose, now gave the following results: Reducing sugar before inversion, 5.10, 2.45, 2.31, 1.77, 1.00; sucrose—chemical method, 5.26, 8.37, 9.50, 10.67, 12.82 sucrose—optical method, 4.96, 8.16, 9.16, 10.32, 12.82. These results show that those beets which contain the most reducing sugar contain the least sucrose, indicating that a large part of the original sucrose had been changed to invert. Also the chem. method of detg. sucrose gives higher results than the Clerget method. The ordinary methods of inversion do not give correct results. The following method of Ogilvie was tried: Make 16.26 g. pulp to 100.5 cc. with cold water without clarification, filter through cotton, pass SO_2 through the filtrate in the cold, neutralize with pure, dry, CaCO_3 , add kieselguhr, mix, and filter; subject 50 cc. of the filtrate to diastasic inversion at 50-5°. Calc. approx. sugar content by polarimetry before and after inversion by the usual Clerget formula. Then by means of a pure sucrose soln. of this strength, det. the Clerget factor for this method, and, by substituting this correction factor in the original polarimetric readings obtain the true sucrose content. The diastase soln. is made by macerating 5 g. compressed yeast 24 hrs. with 100 cc. water and adding to this several drops of CHCl_3 . 10 cc of this soln. will invert 75 cc. of the juice in 5 hrs. The diastase and the usual HCl methods give the same results on normal beets, but with frozen beets the HCl method always gives high results. This would indicate that frozen beets contain some substance which is hydrolyzed by HCl but not by diastase. The amt. of alc. formed in frozen beets exceeds the amount normally formed from the reducing sugar present. It has been shown that the hydrolyzable substances other than sucrose which are found in frozen beets may be transformed into reducing sugar not only by HCl at 89° but also by HCl in the cold and by tartaric or acetic acid at 30°. S. concludes that the alc. formed in frozen beets comes in part from the hydrolyzable substances other than sucrose, which are not modified by invertase but may be transformed little by little into fermentable reducing sugar under the influence of the acids occurring in the fermented juice at 28-30°.

H. R. SMITH.

Drying beet chips in ordinary pulp driers. ROSE AND KIEL. *Z. Ver. Zuckerind.* 65, 205-13(1915).—Attempts to dry sugar beet chips for fodder in pulp driers resulted in caking of the material in the app. and burning, unless very uniformly fed and carefully operated. The yield is about 25% and the dried chips contain 58-64% sugar. One manufacturer grinds the dried chips fine. Ten % of this meal may be added to bread with satisfactory results.

W. L. BADGER.

Report on the cultivation experiments with different kinds of sugar beet seeds carried out during the year 1914 by the Experimental Station of the Zentralverein for the sugar beet industry of Austria and Hungary. O. FALLADA. *Oesterr. Ung. Z. Zuckerind.* 43, 839-46(1914).—The expts. of 1913, a report upon which was published by Strohmer (*Ibid* 42, 894(1913)), were continued during 1914. F. gives a thorough description of the arrangement and *modus operandi* of the cultivation expts. as well as a report on the exam. of the beet tests. Numerous tables give the exptl. data and results.

ISADOR MILLER.

Influence of the arrangement on the soil and sugar beet yield. J. K. GREISENEGGER. *Oesterr. Ung. Z. Zuckerind.* 44, 14-22(1915).—Cultivation expts. with sugar beets on a large scale show the influence of the arrangement on the moisture content of the soil and upon the degree of production of organic substances, the results being in agreement with the expts. of Marek (*Landw. Jahrb.* 33, 357). This influence is due to the resistance which the growing plants offer to the predominant winds according to their position and to the degree of protection they afford the soil from immoderate exposure to the sun.

ISADOR MILLER.

Commercial glucose. G. W. ROLFE. Mass. Inst. Tech. *Science Conspectus* 5, No. 1(1915); *Am. J. Pharm.* 87, 269-77(1915); through *Met. Chem. Eng.* 13, 332-3. —A popular discussion of the com. manuf. and uses of glucose. Solids consisting of maltose 45, dextrose 20, and dextrin 35% are held in suspension in water and treated for 10 min. with a few tenths of 1% HCl in gunmetal boilers under a pressure of 50 lb. steam. The dextrin prevents crystn. and also renders the sirup capable of dissolving considerable sucrose. The solids in glucose also contain 0.3-0.5% mineral matter and 0.08% N. After treatment with acid the liquid is evapd. to 80% solids and is clarified with boneblack. Glucose is used in candies, preserves, and table sirups; also in cheap soaps, and for "filling" leather and tanning exts.

H. R. SMITH.

Is it possible to use breweries which are partially or entirely out of operation for the manufacture of invert sugar and other related branches of industry? A. BAUDREXEL. *Tagess. Brauerei; Deut. Zuckerind.* 40, 320(1915).—In connection with the need, during the war, of fat substitutes for use with bread, B. recommends the use of invert sugar sirup and suggests that breweries which are partly or entirely idle at the present time in Germany could be readily adapted, by reason of their equipment, to the manuf. of this product. A satisfactory product has been prepd. by dissolving 100 kg. sucrose in 27-30 kg. hot H₂O which contains 0.5 kg. CaCl₂, 1 kg. NaCl and 300 g. citric acid (or 150-250 g. tartaric acid) and heating to boiling point for 1/4-1/2 hr. The salts are added to improve the flavor and because of their nutritive value, while the citric or tartaric acid gives an agreeable fruit acid taste. The invert sugar sirup thus prepd. is recommended for the production of artificial honey (by addition of artificial flavors or some pure honey) and fruit sirups, jellies and preserves. It is believed that the manuf. of invert sugar would stimulate the consumption of sugar as a substitute for the more expensive and less abundant fats, such as butter.

H. S. PAINE.

Bone black. F. G. WIECHMANN. *Sugar* 17, 34-8(1915).—A concise review covering the historical, technical and analytical sides of the subject.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

The new dehydration theory of leather formation as opposed to the oxidation theory. E. O. SOMMERHOFF. *Collegium* 1915, 26-37.—Chemically fixed water of hydration is withdrawn from hide albumin by the action of partly oxidized tannins. The H acceptor is the colloidal basic phlobaphene, the O acceptor the complex tan-acids. S. was led to substitute this theory for the oxidation theory of Fahrion and Meunier by his studies on chrome tannage. Vegetable and chrome tannage are discussed in some detail. S. considers oil tannage similar, and hopes to show it in detail later.

L. B.

Degree of tannage. W. JAMES. London. *Collegium* 1915, 76-7.—Where "bloom" has been brushed on to the flesh side of leathers, the figure for "organic insolubles" is raised, and by the usual calculation the "degree of tannage" is raised. This J. thinks incorrect, and suggests that the mode of calculation be modified.

L. B.

The analysis of tanning materials. ALEXANDER T. HOUGH. *J. Soc. Chem. Ind.* 34, 472-3(1915).—H. criticizes suggestions made by Bennett (C. A. 8, 3870) for the improvement of the official method of analysis of the Intern. Assoc. of Leather Trades Chemists. He states that the higher non-tannins are not due to the diln. of the ext. solns. but to the fact that 26.5 g. of hide powder are now being used to detannize 200 cc. instead of 100 cc. The less concd. hide powder cannot do as much work in the specified time. If the quantity of tannin in the soln. be decreased by 50% and 100 cc. be shaken with 26.5 g. of wet chromed hide powder, the non-tannin will be lower than with a stronger soln. because the hide powder quickly absorbs the tannin and commences to absorb the non-tannins. It would seem best to use tannin solns. of the present official strength and reduce the quantity of hide powder so that the detannization is just effected. H. is opposed to changing the time of shaking and suggests

that the quantity of hide powder should be such that the official quarter hour is just sufficient for it to do its work. In regard to tannery liquors H. agrees with Bennett except in regard to dilg. solns. for the estn. of non-tannins as mentioned above. H. also suggests the possibility of reducing the acidity of all tannery liquors to some set standard, either by the lime water method or by the Wood, Sand and Law method (cf. C. A. 6, 1075), then adding standard soda to neutralize to a certain fixed point (slightly acid) and then detannizing without diln. The use of unwashed hide powder does not seem advisable.

J. S. ROGERS.

The analysis of tanning materials. A reply. H. G. BENNETT. *J. Soc. Chem. Ind.* 34, 473(1915); cf. preceding abstr.—In replying to the criticism by Mr. Hough B. upholds his original statements. He agrees with H. that it is undesirable to extend the time of shaking. B. has not found it necessary to extend the time of shaking in his method, which he has used over 2 yrs. He states that H.'s quotation with regard to extension of time of shaking did not refer to the revized method suggested, but to possible future expts. planned with the object of detg. the smallest possible amt. of hide powder which could be used for complete detannization. J. S. R.

Distinction and detection of tanning materials and cellulose extract in leather. R. LAUFFMANN. *Ledertech. Rundschau*, Dec. 24 and 31, 1914.—Nine pieces of hide were tanned with various materials and mixtures. The finished leather was extd. with water and the ext. tested by the formaldehyde reaction, Br water, the Procter-Hirst reaction, and several other tests. It was found that the ext. gave such tests as would be expected from the materials used in tanning. Three samples which were tanned partly with cellulose ext. gave the Procter-Hirst reaction (ppt. with aniline and HCl), but when the leather was 3 months old the reaction was much less distinct. The method of Moeller (extn. of leather with dil. NaOH, ext. neutralized with HCl, Procter-Hirst test applied) gave no result with the 3 months old samples. L. B.

Detection of sulfite-cellulose in leather. W. MOELLER. *Collegium* 1915, 99-101.—M. believes Lauffmann's failure (cf. preceding abstr.) to obtain positive results by his method applied to old leathers tanned with sulfite-cellulose is due to too fine division of the leather. L. B.

Detection of cellulose extract in leather. R. LAUFFMANN. *Ledertechnische Rundschau*, April 22, 1915, 121-3.—Repeating the tests on the 3 leathers mentioned above by Moeller's method, the leather being cut instead of ground, all gave positive results. Boiling with H₂O gave equally good results, so L. concludes that extn. with alkali is not necessary. L. B.

Tanning with formaldehyde. *Shoe and Leather Rep.* 117, No. 9, 61-63; No. 10, 57-9(1915).—By the Eitner process, sheepskins in the pelt form after the beamhouse work are treated for 24 hrs. in a liquor 0.5 part com. HCHO to 100 parts water. They are then neutralized with a weak alk. soln. A mixt. of (NH₄)₂SO₄ and Na₂CO₃ is good. The skins are then washed in clean water and allowed to drip. Next they are turned for 1 hr. in the fat liquor (100 parts neatsfoot oil, 25 parts Na₂CO₃, and 500 parts of water). The product is very supple and of the nature of ordinary alum tanned leather, although the grain is fuller and more brilliant. The flesh side may be made velvety by the use of an emery wheel. By adding a little first quality moellon in the soap fat liquor extremely supple yellow skins are obtained. Neatsfoot oil and clear cod oil produce white skins. For each skin from 60 to 70 g. of grease are necessary. Finishing may be done as for chamois or mocha. Careful buffing removes the harsh grain and leaves a velvety surface. The process for sheepskins may be varied as to time, strength of solns., etc. For HCHO tannage of kips, the skins are soaked about 2 days in a soln.

of 2 parts NaOH or 5 parts Na_2S to 1000 parts water; then 6 hrs. in pure water. They remain in the lime liquor (5 parts $\text{Ca}(\text{HS})_2$ to each 100 parts of skins) for 5 to 6 days, are washed in tepid water, and then tanned in a pit (12 to 13 days) or a paddle (5 days). The soln. is 2.5 parts com. HCHO to 100 parts of water. The tannage is continued until a section cut from the skins will stake properly. They are then washed, neutralized if necessary, fat-liquored (3 parts good white olive soap to 100 parts water—extra oil may be added to make skins particularly supple), and washed. The skins are then dried and staked thoroughly. White skins are rubbed over with talc, zinc white or lithopone. HCHO liquor may be strengthened and used for a second lot of skins; very poor weighing leather results, however. Other salts as NaHSO_4 , alum, or hypo may be used in place of alkali carbonate. HCHO seems to cause the fibers of the pelt to be so sepd. that other tannins penetrate more quickly, although fixation is not necessarily more rapid. The application of a soln. of HCHO to the grain surface before drum tanning is not recommended as it may cause a brittle grain. A HCHO bath previous to either vegetable or chrome tannage has been found by Thuau to reduce the time very much and to produce a satisfactory product. The use of HCHO with both basic and acid coloring matters is patented. HCHO may be used for brightening vegetable tanned leather. The use of glycerol and sugar is not recommended. Eitner found that a raw calf skin rubbed with a weak aq. soln. of HCHO along with MeOH kept fresh for 4 weeks. On being placed in water the hair slipped easily although the skin was fresh and sterile. To harden the grain, sheepskins (perfectly free from lime) are placed in a 0.05% bath of HCHO for 4 hrs. Calf skins are first bated and scudded and then placed in a HCHO bath up to 6 hrs. Skins for burnished leather are completely delimed and then placed in the HCHO bath for 12 hrs. Placing fur skins in a 0.5% HCHO soln. hardens the grain so the hairs are held more tenaciously. The skins are placed in a paddle with the soln., turned $\frac{1}{2}$ hr., dried $\frac{1}{2}$ hr., and turned for 1 day. They are then neutralized with a soln. of 250 g. soda and 250 g. $(\text{NH}_4)_2\text{SO}_4$, washed and put over a horse to drip. A mixt. of egg and flour with dextrose if necessary is placed on the flesh side and the hairs are degreased. J. S. ROGERS.

Artificial bates. J. T. WOOD. London. *Collegium* 1915, 82-5.—Several bates recently placed on the market are discussed and analyses given. L. B.

Russian, particularly Caucasian, tanning materials. V. G. POVARIN AND V. TOLKUNOV. *J. Russ. Phys. Chem. Soc.* 46, 1343-6 (1914).—The methods previously used for the exam. and classification of willow barks (cf. C. A. 8, 1031) were applied to numerous samples of tanning materials obtained chiefly from the Caucasus. The results are given in an extensive table that cannot be briefly abstracted.

H. M. GORDIN.

Apparatus for determining the melting point of paraffin waxes (SMALL) I.

U. S., 1,141,224, June 1. O. C. E. P. WAWRZINIOK. **Making artificial leather** by coating woven fabric with a plastic mixt. containing nitrocellulose and oil paint and exposing the coated fabric to the action of hot solvent vapor to render the coating firmly adherent and pliable.

U. S., 1,141,545, June 1. R. O. HERZOG and A. MEIER. **Substitute for ordinary leather** formed of a layer of split leather or other strengthening and backing material with an attached layer formed by growing bacteria or fungi, e. g., *B. xylinum*, *B. xylinoides* or *Mucor boidin*, on the material and tanning the layer. Before tanning, the growth may attain a thickness of 30 cm., which is reduced 95-97.5% by tanning.

Ger., 280,216, Aug. 28, 1912. J. STOCKHAUSEN. Mfg. articles from gelatin casein, and similar plastic masses. The articles are wrapped up in moist paper and heated.

Ger., 281,268, Dec. 21, 1912. Addition to 277,653 (C. A. 9, 1136). J. STOCKHAUSEN. Mfg. elastic and plastic masses from glycerol-gelatin, and the like. If finely powdered colophonium, copal, or the like, be added to the masses obtained according to the principal patent from glycerol-gelatin, camphor, and S, a favorable action shows itself even after a short period of heating. However, after heating for a long time, say 3 days, the mass becomes homogeneous, the particles of S, camphor and resin, which were before discernible, disappear, and the toughness of the mass increases. While the masses without the addition of resin break and become friable in the heat, those with the resin addition are tough even in the heat, and do not crumble; they also exhibit a certain degree of plasticity. E. g., 125 g. gelatin are dissolved in 125 g. glycerol and ground up intimately with 5-10 g. S, 20 g. camphor, and 10-50 g. colophonium. They are then hardened with 10-20 g. HCHO (4%) or 3-10 g. $\text{Na}_2\text{Cr}_2\text{O}_7$, and heated for a long time.

Ger., 281,541, Nov. 12, 1913. GRAF FRANZ VON KEGENECK. Mfg. a celluloid substitute from gelatin and casein. To a mixt. of glue or gelatin which, after softening, is melted in H_2O , are added casein and water-glass, and the product is then, in the known manner, rendered insol. by means of a hardener such as alum. A transparent, light-colored product is obtained, which is made readily and without danger, is combustible and easily worked. E. g., 200 g. gelatin or glue, after being softened in H_2O , are melted with heating, whereupon 30 g. casein, 30 g. water-glass, and if necessary a transparent dye, are added. The mass is stirred well, then filtered and discharged upon a level glass plate. After drying, the mass is left for several hrs. in tanning baths (chrome alum, alum, tannin, or the like). Even before complete drying, the mass becomes insol. in H_2O .

CHEMICAL ABSTRACTS

Vol. 9.

AUGUST 20, 1915.

No. 16.

I. APPARATUS.

L. C. JONES.

Origin and development of the ultramicroscope. O. SCARPA. *Ann. chim. applicata* 3, 295-313(1915). S. LEVY.

Apparatus for the continuous extraction of a liquid by another and heavier liquid. I. GREENWALD. *J. Ind. Eng. Chem.* 7, 621(1915).—The app. described and illustrated is simple, compact and can be made easily by any glass-blower. ISADOR MILLER.

A modified pipet. S. BORN. *J. Ind. Eng. Chem.* 7, 621(1915).—A stopcock and bent glass tubing are fused to the ordinary pipet. ISADOR MILLER.

New tube for the rapid distillation of ammonia. E. POZZI-ESCOT. *Ann. chim. anal.* 20, 125-6(1915).—See fig. To effect a rapid distn. of NH_3 without entraining fine particles of NaOH the tube shown in cut was devised. The outer coil also serves as a cooler. F. W. SMITHER.

Indicator stopper for distillations. ANNIBALE FERRARO. *Boll. chim. farm.* 53, 8-9(1914).—The tube connecting the distg. flask with the condenser in the app. for detn. of total N by the Kjeldahl method is bent to an obtuse angle and the portion of the tube constituting the side of the angle next the condenser is equipped with a small tubulature provided with an accurately fitting glass stopper. The portion of this stopper which enters the tube consists of a small reservoir which is perforated in the direction of the axis of the tube so as to permit passage of NH_3 vapor. When one desires to ascertain whether or not the evolution of NH_3 vapor from the distg. flask has ceased, this stopper is quickly replaced by a similar stopper, the reservoir of which contains $\frac{1}{2}$ drop of tincture of red litmus (or preferably very dil. phenolphthalein soln.). The removed stopper (after addition of $\frac{1}{2}$ drop litmus or phenolphthalein soln. to the reservoir) may be re-inserted when it is desired to repeat the test. Suitable tests showed that no detectable amt. of NH_3 vapor is lost during removal of the 1st and substitution of the 2nd stopper. H. S. PAINE.

Adiabatic calorimeter. V. SVYENTOSLAVSKII AND I. PAKOVICH. *J. Russ. Phys. Chem. Soc.* 46, 1284-93(1914).—Richards' adiabatic calorimeter (*Z. physik. Chem.* 52, 551) has the following drawbacks: It requires a large amt. (about 25 l.) of NaOH soln. to fill the outer jacket; the latter cannot be readily cooled without removing this soln. and replacing it by a cooler one; the soln. cannot quickly be heated throughout uniformly, the stirrer being placed in the lower part and to one side of the app. All these faults are remedied by the authors' new calorimeter whose construction is minutely described. Its essential features are an arrangement for heating the outer shell by the elec. current, and for cooling it by means of cold H_2O circulating through a Pb coil. As filling kerosene is used, and the stirring is done by a special device. Drawings of the whole app. and of the heating device are given. A detailed discussion of the correc-

tions to be used in calcg. the thermal data is entered into. With respect to the heat evolved by the friction between stirrer and liquid, it was found that when the stirrer does not touch the sides of the jacket the amt. of heat due to this source is negligible. The correction for the heat of evapn. of H_2O from the top of the calorimeter is entirely avoided by covering the latter with a layer of kerosene. As to the influence of the unavoidable difference between the temps. of the calorimeter proper and the outer jacket on the heat of radiation, it is shown that in the new app. this difference is reduced to insignificant proportions, and that in general a difference of even 0.2° has little influence on the heat of radiation. Cf. *C. A.* 9, 2180.

H. M. GORDIN.

A simple instrument for the determination of viscosity. A. SPEEDY. *J. Soc. Chem. Ind.* 34, 597-8(1915).—To avoid the difficulty in reading the marks with such app. as the Ostwald viscosimeter, the instrument shown in cut was devised. The marks are placed above the surface of the liquid which, therefore, need not be transparent.

*Two-thirds
scale*

The app. consists of a piece of glass tubing drawn out to form a capillary and bent into U shape. The liquid, the viscosity of which is to be detd. is filtered into the viscosimeter, which is clamped vertically in the bath so that the level marks, aa' , are just above the surface of the heating liquid. The bath is then heated to the required temp. and after a few mins. the levels, aa' , are carefully adjusted. By means of a piece of rubber tubing the liquid is then slowly sucked up the left limb of the tube until it passes the level, b . It is then allowed to descend; the time taken to fall from b to c is recorded. Part of the liquid under observation is above the surface of the heating liquid and is, therefore, at a slightly lower temp., but as the level falls, this part of the liquid regains its former temp. The error due to unequal viscosity in different regions arising in this way is negligible, as it is only the viscosity of the liquid in capillary tube that counts. The thinness of the wall of the capillary tube ensures that the liquid passing through the tube is at the temp. of the bath. The column of liquid, bc , never reaches the capillary. The level b' is well above the point where the constriction in the right limb of the tube begins. The time of flow from b to c only, is taken because on approaching a the motion becomes slow and uncertain. The const. of the instrument can be obtained by calibrating it with pure phenol or H_2SO_4 (cf. Dunstan, *C. A.* 6, 1702; 9, 405). The instrument may conveniently be strapped to a thermometer and suspended in the heating liquid contained in a boiling tube. The cheapness of the app. renders it possible to choose from a range of tubes one with a capillary of diam. best suited to the viscosity of the liquid to be examined. The best results are obtained if the time of flow is about 1-2 mins. at the temp. of observation. Results are reported on 6

oils using the above instrument, the totally immersed type of Dunstan and the Redwood form. The readings of the first 2 instruments agree within the limits of exptl. error. At 60° Redwood secs. may be obtained approx. by multiplying these readings by 500.

F. W. SMITHER.

An electromagnetic vacuum balance. J. S. ANDERSON. *Trans. Faraday Soc.* May 11, 1915 (7 pp.) (advance proof).—A. describes in detail with photographs and drawings an electromagnetic vacuum balance devised for the measurement of the velocities of absorption of vapor or gas by such porous substances as silicic acid gels.

The principle involved is that of the Kelvin balance for "weighing" elec. currents. One of the scale pans of an ordinary balance is replaced by a circular coil of wire whose axis is vertical; this coil is movable between 2 larger fixed coils of wire, which have the same vertical axis. The 3 coils are so connected that an elec. current may be passed through them in series, through the movable coil and the lower fixed coil in one direction and through the upper fixed coil in the opposite direction. Thus when one elec. current is passed through the coils, the movable one is attracted towards the lower, and repulsed by the upper, fixed coil. These attractive and repulsive forces may be varied with the current and used to counterbalance the force of gravity acting on the substance to be weighed in the scale pan hanging from other end of beam. The whole is enclosed in a bell jar which can be evacuated. Cf. Urbain, *C. A.* 6, 1080; Anderson, 8, 3141.

F. W. SMITHER.

Experiments with thermometers with vacuum mantles. GOTTFRIED DIMMER. *Z. angew. Chem.* 28, I, 255(1915).—Hahn (*C. A.* 8, 1221) has proposed this as a means of eliminating the stem correction. D. states that the cond. of a gas is independent of its density, and hence the device is useless. Two thermometers so constructed (scales 10 and 59 cm. long, resp.) were arranged with connections to a Gaede pump and an X-ray tube. When immersed up to the zero in a flask at 100° and with air in the jacket at atm. pressure, the stem corrections were 1.0 and 0.93°, resp. When the pressure was lowered to an X-ray vacuum, neither thermometer showed any change in the correction. Some further minor corrections to H.'s article are appended.

W. L. BADGER.

A convenient thermostat for accurate specific gravity determinations and gas-pressure regulator. K. C. BROWNING AND C. T. SYMONS. *Trans. Faraday Soc.* May 11, 1915 (4 pp.) (*advance proof*).—The authors describe in detail with drawings a heavy gage Cu tank thermostat devised for use in detg. the sp. gr. of alc. (cf. *C. A.* 9, 117). The gas pressure regulator consists of a brass cylindrical casting, walls 3-4 mm. thick, 16 cm. internal diam., and about 16 cm. high. Near the bottom is a brass partition which carries the valve bush and seating. The bottom is a heavy brass plate screwed into the cylindrical casting. It is provided with a squared recessed boss in the center; the recess takes a key which is used to unscrew the bottom and enable the valve to be got at for grinding in when necessary. The top consists of a sheet of rubber insertion held in position by a brass ring, screwed by 16 screws into a flange. Through the center of the rubber passes the valve stem secured by 2 nuts and concave-convex brass washers. A large brass washer 11 cm. in diam. is placed above the rubber. The concavity of the washers is slight and should be such as to let the rubber insertion fit snugly to the washers when it is raised a little. At the top of the valve stem is a cup, in which wts. can be placed. The valve must move freely and the stem be dead true. The contact between the valve and seating must be very narrow. The valve is ground into its seating with 220-mesh carborundum powder and finished with FF carborundum. *Advantages:* No leakage at the valve or at the flexible top. It is portable and takes up little room; can be rapidly set for any desired reduction of pressure; does not require careful leveling and is very strong.

F. W. SMITHER.

Method of paraffining labels. D. L. RANDALL. *Chem. Analyst* 13, 25(1915).—Dissolve paraffin in CCl_4 . Use satd. soln. as a varnish. H. M. LANCASTER.

The activation of chlorates by formic acid. K. A. HOFMANN AND K. SCHUMPFELT. *Ber.* 48, 816-22(1915).—The fact that, when chlorates are "activated" by Os_2O_5 and carbonaceous matter is oxidized in their presence, the oxidation proceeds in two stages, resulting in first a slow and later a rapid evolution of CO_2 , was found to be due to the formation of HCOOH . The "activation" of chlorates by HCOOH is not dependent on the acidity of the latter. $\text{CH}_3\text{CO}_2\text{H}$, $\text{CH}_3\text{CICO}_2\text{H}$ and $\text{CCl}_3\text{CO}_2\text{H}$ and H_2PO_4 in strengths equiv. to the solns. of HCOOH that were used did not activate chlorate solns. Exptl. work on the rate of formation of ClO_2 and CO_2 in mixts. of NaClO_3 and HCOOH is recorded and also expts. on the oxidation of indigo sulfate, $\text{C}_6\text{H}_7\text{NH}_2$ and anthracene by chlorates in the presence of HCOOH . The work showed that by the reduction of chlorates by HCOOH , ClO_2 is formed; this oxidizes such compounds as indigo sulfate, $\text{C}_6\text{H}_7\text{NH}_2$, etc. This is analogous to the activation of atm. O by reducing agents. A reducing "activator" acts upon an oxidizing agent to form a more actively oxidizing substance. It follows that oxidizing and reducing agents cannot be classified by means of their electrochem. properties, but in each case the activity of the oxidizing agent depends upon the special nature of the reducing agent. E. W. BOUGHTON.

Substances in the colloidal condition. CARLO MAZZOLI. *Boll. chim. farm.* 52, 903-4(1913).—In connection with the consideration of the internal structure of colloidal substances M. takes exception to the statements of Carcano that colloids may be regarded as being in a condition (designated by the term "micellae" (Nägeli)) similar to the ionic state and that colloidal I produced from HI may be regarded as existing

in an "ionic" grouping, so to speak. The physical and chem. properties of colloids indicate that the latter are in a transitory state which is essentially neither a purely molecular nor atomic grouping (inasmuch as certain physical properties are modified or lacking), but partakes of certain characteristics of these conditions. From a purely chem. standpoint the colloidal condition may be regarded as a peculiar form of aggregation which has much in common with the nascent state.

H. S. PAINE.

Causes of decolorization of the colloidal solution of arsenic sulfide and conditions under which it takes place. N. P. PRSKOV. *J. Russ. Phys. Chem. Soc.* 46, 1619-45 (1914).—It was shown by Vorländer (*C. A.* 7, 2881) that when H_2S interacts with As_2O_3 in very dil. soln. the latter remains colorless, but that the CO_2 of the air or the addition of electrolytes or other substance capable of coagulating colloids colors the soln. yellow. V. explains this by assuming the formation of a colorless unstable mol. combination $xAs_2O_3 \cdot yH_2S$, which the addition of the above substances converts into yellow As_2S_3 . This explanation P. considers unsatisfactory. The fact that just those substances which are capable of coagulating colloids impart color to the soln. clearly indicates that the colorless soln. already contains colloidal As_2S_3 in a colorless form, and that these substances merely change the form of the colloid from colorless to yellow. P. assumes that the colorless and the yellow As_2S_3 differ from each other in 2 respects: the individual particles are of different size, and while in the colorless soln. these particles exist as individual units, in the yellow soln. the latter form aggregates of several units each. This is supported by the fact that the colorless soln. is obtainable only in presence of an excess of As_2O_3 or, as shown by P., in presence of gelatin. With the latter colorless solns. are obtainable in even higher concs. of As_2S_3 than were used by V. The As_2O_3 and the gelatin have the power of stabilizing the individual particles, preventing them from forming yellow aggregates, while electrolytes and other coagulators have the opposite effect. As to the nature of the individual particles in the colorless soln., they must also be regarded as colloids, and not as crystalloids. This is proved by the fact that an elec. current passed through the colorless soln. transports the As_2S_3 like other colloids, and does not leave it where it is, as it does with cryst. nonelectrolytes, or decomp. it, as it does with cryst. electrolytes. Expts. were also carried out in order to prove that the decolorization of V.'s soln. is not due to the hydrolysis of As_2S_3 to As_2O_3 and H_2S . For this purpose a yellow soln. of As_2S_3 was gradually dild. with H_2O , and the changes in the intensity of color plotted against the changes in concn. The resulting curve was found to be a straight line, showing that it is not hydrolysis that influences the color, since if this were so the diminution in the intensity of the color ought to change faster than the concn., giving a curve that is inclined towards the axis of intensities. An app. is described in which the transport of As_2S_3 can be shown, and numerous tables and curves illustrate the article.

H. M. GORDIN.

Electrical conductivity of colloidal solutions. H. NORDENSON. *Upsala. Kolloid-Z.* 16, 65-9 (1915).—The max. charge of a colloidal or suspended particle is proportional to its radius. If a substance be in the one case in electrolytic soln., in the other case colloiddally dissolved the ratio of the conds. will be inversely as the square of the radii; thus the cond. of a colloid of known concn. and degree of dispersion can be calcd. It follows that the cond. of moderately concd. and moderately dispersed colloids, e. g., metal sols., does not reach measurable values. The values obtained experimentally are due to the small amts. of electrolytes present. In colloids of very high concn. and high degree of dispersion, especially non-metallic colloids, the cond. may reach measurable values, but here too the influence of adsorbed electrolytes must be considered.

H. I. MATTILL.

The formation of colloidal solutions by flames or electrical spark discharge. J. DONAU. *Graz. Kolloid-Z.* 16, 81 (1915).—Reduction of a gold chloride soln. by playing

an oxy-hydrogen flame upon the surface results in a violet or blue colloidal Au, because of the greater amt. of oxides of N formed. A hydrogen flame gives a red colloidal Au. A spark discharge just under the surface of a AuCl_3 soln. soon forms red colloidal gold, undoubtedly due to the reducing action of the oxides of N. H. I. MATTILL.

Colloidal gold formation. F. HARTWAGNER. Munich. *Kolloid-Z.* 16, 79-80 (1915).—By exposing AuCl_3 solns. containing hexamethylenetetramine, H_2O_2 , oxalic acid; EtOH, HCHO, MeCHO and paraldehyde, to diffused daylight, direct sunlight and the light from a Hg vapor lamp it was found that the reduction occurred most rapidly in sunlight and least rapidly in diffused daylight, the color of the colloidal gold formed in these cases being the same, and usually differing from that formed by exposure to the Hg vapor lamp. H. I. MATTILL.

Seeding action in gels. R. E. LIESEGANG. Frankfurt. *Kolloid-Z.* 16, 76-9 (1915).—Observations on gaseous seeding, the seeding action of non-cryst. substances and of "Vorkernen." Not suitable for abstracting. H. I. MATTILL.

Capillary constant of sea water. A. BERGET. *Compt. rend.* 160, 677-8 (1915).—The difference between levels in tubes of different sizes joined into a U was measured with a cathetometer for an artificial sea water, for natural sea water at several dilutions, and pure H_2O , at 0° and 12.5° . The capillary const. in mg. per mm. was 7.357 for pure H_2O , 7.553 for sea water, and 7.587 for the artificial mixt. The correction to be applied to areometer readings on account of this change is about 0.1%. E. B. MILLARD.

Experiments on emulsions. II. T. R. BRIGGS AND H. F. SCHMIDT. Cornell. *J. Phys. Chem.* 19, 479-99 (1915); cf. Newman, C. A. 8, 1039; Bancroft, C. A. 9, 1567. —The influence of time of shaking, soap concn., and the presence of Na resinate, Fe(OAc)₃, gelatin or free alkali on the formation of C_6H_6 - H_2O emulsions at "room temp." has been studied. In the presence of a suitable emulsion builder the relative amts. of the 2 phases present are without importance, the character of the emulsion depending on the interfacial membrane. If the concn. of soap in the aq. phase is over 0.01%, the ease with which C_6H_6 is emulsified is more or less const. Free alkali at low concn. has a peptizing action, and at higher concns. emulsification is retarded by it. E. B. MILLARD.

Theory of emulsification. VII. W. D. BANCROFT. *J. Phys. Chem.* 19, 513-29 (1915); cf. C. A. 9, 1567.—The Gibbs theorem in regard to the concn. in the surface film of substances which lower the surface tension applies only to substances in true soln., but a similar theorem probably applies to suspended particles. The concn. of peptone in a surface film does not give rise to the large differences of osmotic pressure calcd. by Metcalf (*Z. physik. Chem.* 52, 1 (1905)). While the presence of adsorbed gases may be a factor in causing the formation of a solid film, it probably plays only a minor part. The solid film which forms over Hg or Zn amalgams is an oxide; that over FeCl_3 solns. is probably hydrous Fe_2O_3 , and that over CoCl_2 is a carbonate formed by the action of $(\text{NH}_4)_2\text{CO}_3$. There was no reason for postulating an insol. modification of peptone; similar results can be obtained with colloidal Ag. E. B. MILLARD.

Adsorption in solution. VIII. Distribution law. G. GEORGIEVICS. *Monatsh.* 36, 391-405 (1915); cf. C. A. 8, 2832, 3735.—Sorption and the anomalous distribution of a substance between 2 non-miscible liquids are to be regarded as the same sort of process. The accepted theory of distribution which states that only the undissociated mols. are concerned in the distribution equil. is wrong, according to certain expts. by G., in which only when the total amt. in each phase was considered, were rational results obtained. If only the undissociated mols. were used in the calcn., the impossible result was obtained that piperidine was more associated in H_2O than in C_6H_6 . The assumption that only the undissociated mols. are distributed appears improbable,

since the values of the degree of dissociation obtained from f. p. detns. do not agree in many cases with α values from distribution expts. between C_6H_6 and H_2O . G. has made new detns. of the distribution of $CHCl_2COOH$ and $CH_2ClCOOH$ between H_2O and C_6H_6 , from which it was shown that the values of α increased from mono- to tri-chloro acid, just as the viscosities, and therefore the affinities for H_2O , do. Finally expts. on the distribution of pyridine, piperidine and hydrazine between C_6H_6 and H_2O showed that this equil. followed essentially the law of Henry, i. e., $\alpha = 1$. E. B. M.

Electron conception of valence. VII. Theory of electrolytic dissociation and chemical action. K. GEORGE FALK AND J. M. NELSON. *J. Am. Chem. Soc.* 37, 1732-48(1915); cf. *C. A.* 8, 1363, 1364.—F. and N. believe that "changes occurring in chem. reactions do not depend upon the electrolytic dissociation of the reacting substances. The chem. changes are accompanied very often by electrolytic dissociation phenomena, but the latter parallel the former (or *vice versa*) and do not necessarily precede or cause them." In the reaction between alkyl halides and amines to form substituted NH_4 halides and the decompn. of the latter into amines and alkyl halides, in general terms each of the positive groups in the NH_4 compd. may unite with the negative group and

there will be as many possible equil. of the type $NRRRRX \rightleftharpoons NRRR + RX$ as there are different R's; of the possible reactions only those which proceed with the greatest velocities and where one or more of the products are removed from the sphere of action will occur to a perceptible extent. The reactions involve no electrolytic dissociation but the formation of an "onium" compd. which, after its formation, may show electrolytic dissociation in suitable solvents. With this as the keynote, a number of apparently separate reactions may be correlated on the assumption of the formation

of oxonium compds. Thus we may have $Me_2O.HCl$ in equil. with $MeOH + MeCl$ or

$Me_2O + HCl$, $MeOR.HI$ with $ROH + MeI$, $ROMe + HI$ or $MeOH + RI$ (Zeisel

method for MeO detns.), $HOR.HX$ with $H_2O + RX$ or $ROH + HX$, $HOH.AcCl$ with

$HCl + AcOH$ or $H_2O + AcCl$, $AcOH.AcCl$ with $HCl + Ac_2O$ or $AcOH + AcCl$,

$MeOH.AcCl$ with $MeOAc + HCl$, $MeOH + AcCl$ or $AcOH + MeCl$, $(R'CO)OR.H-$

(OH) or $ROH.(R'CO_2)H$ with $ROH + R'CO_2H$, $H_2 + R'CO_2R$ or $ROH + R'CO_2H$.

"Onium" compds. possibly react more rapidly than do their constituents when not combined in the onium form. Thus, the rapidity of the reaction $NH_3 + HCl \rightleftharpoons NH_4Cl$ in the moist as compared with the dry state may be due to the fact that H_2O is made up of "double" and perhaps more complex mols. ($H_3O.OH$, etc.) in which oxonium O is already present; these double mols. react rapidly with HCl and the resulting oxonium chlorides then react rapidly with NH_3 . Similarly, the catalytic action of HCl in esterification or sapon. may be explained as due to the formation of an oxonium chloride of the acid or ester which then reacts rapidly to form a new oxonium compd. by the addition of Cl and the positive complex to the O of the alc. or of the H_2O . In support of their views, F. and N. point to the large number of facts regarding oxonium salts which has been accumulated in recent years. Both the nature and the strength of the acid and the character of the org. compd. influence their readiness of formation and their stability. Their formation need not be considered as connected with the electrolytic dissociation. Turning to inorg. compds., in the case of a bivalent metal halide, MX_2 , in H_2O the compd. $M[O(H_2)X]_2$ will be present and negative X combined with O carrying a predominantly negative charge will ionize into $[M(OH_2)_2]$ and $2X$ or the compd. may hydrolyze into $M(OH)_2 + 2HX$; addition of a base removes HX and produces further formation of $M(OH)_2$. Similarly, in NH_3 the compd. $M[N(H_2)X]_2$

++ -

dissociates into $[M(NH_3)_2]$ and $2X$ but apparently there is no ammonolysis into $M(NH_3)_3$ and HX , so that the reaction between a base and MX_2 in H_2O in the presence of NH_3 salts or NH_3 will depend upon the relative amts. of the hydrated and ammoniated salt present; if there is an appreciable amt. of the former, $M(OH)_2$ may be pptd.; if only the latter is present, no $M(OH)_2$ will be pptd.

C. A. ROULLIER.

Electrical conductivity and diagram of state of the system benzoic acid-pyridine.

II. A. BASKOV. *J. Russ. Phys. Chem. Soc.* 46, 1699-716(1914).—An exam. of the system $BzOH$ -pyridine, similar to that previously made with the system $BzOH$ -aniline (cf. *C. A.* 8, 451), gave the following results: There is a definite chem. compd. containing 1 mol. each of base and acid, corresponding to a max. at 43.7° on the fusion curve. The system also contains 2 eutectics, at about 55 mol. % of $BzOH$ and 42.8° , and at about 5 mol. % of $BzOH$ and -41° . The cond. curve has a max. at 66 mol. % of $BzOH$ and up to 125° the temp. coeff. is positive and is gradually displaced in the direction of 50 mol. % of $BzOH$. Above 125° the chem. compd. begins to decomp., and the curve then has a negative temp. coeff. with a negative max. also at 66 mol. % of $BzOH$. The explanation of the appearance of a negative temp. coeff., as given in the former investigation, holds good in this case too.

H. M. GORDIN.

Anomalous electrolytic dissociation. A. N. SAKHANOV. *J. Russ. Phys. Chem. Soc.* 46, 1646-59(1914).—An exhaustive review of the work done by the author and other investigators on this subject. No entirely satisfactory explanation of this anomaly is known.

H. M. GORDIN.

Electrical conductivity in mixed solvents. A. G. DOROSHEVSKII AND S. V. DVORZHANCHIK. *J. Russ. Phys. Chem. Soc.* 46, 1676-99(1914).—Since in detg. the conditions of isohydry in mixed solvents (cf. *C. A.* 8, 288, 2515, 3143) it is necessary to have an exact method for calcg. the changes in the elec. cond. caused by diln., D. and D. examd. the proposed diln. formulas and the rules of Lenz and Cohen (*Z. physik. Chem.* 25, 1(1898)), Arrhenius (*Ibid* 9, 487(1892)) and Wakeman (*Ibid* 11, 49(1893)). Taking the results of their own former expts. as well as those of other investigators on the cond. of salts in mixed solvents, the following conclusions are arrived at: For solns. of strong electrolytes in H_2O + alcs. ($MeOH$, $EtOH$) the same diln. formulas are applicable as when the solvent is H_2O . The most suitable diln. formula within narrow intervals of conc. is $\lambda = A - a/\sqrt{v}$ in which A and a have the same values as in their former investigations, v is the diln., and n differs with the nature of the salt, being, e. g., 3 for Na and K halides, 4 for $BaCl_2$ or $Ba(NO_3)_2$, and 8 for Na_2SO_4 , K_2SO_4 , Na_2CO_3 and K_2CO_3 . The rules of Lenz-Cohen and Arrhenius are wrong. Wakeman's formula holds good for salts giving monovalent ions in H_2O + $EtOH$. For salts with divalent ions, e. g., $BaCl_2$ or $Ba(NO_3)_2$, in H_2O + $EtOH$, W.'s formula is applicable when it is given the form $\Delta^2/p(100-p) = k$, where x varies with the nature of the salt.

H. M. GORDIN.

Relation between viscosity and chemical constitution. IX. **Viscosity and fluidity of the aliphatic acids.** A. E. DUNSTAN. *J. Chem. Soc.* 107, 667-72(1915); cf. *C. A.* 8, 2291.—Detns. of viscosity by the transpiration method for 10 aliphatic acids at several different temps. Each detn. was made in 2 different viscosimeters, after their consts. had been detd. from time of flow for 8 standard liquids. The values for each acid fell on a smooth curve, which showed the rapid decrease in viscosity as the temp. rose. The CH_2 increments decreased steadily as the series was ascended, though there was some irregularity between C_4 and C_5 . Neither fluidity nor log. viscosity was strictly additive, but both are more nearly so than viscosities. The additivity of log. viscosity for these acids was somewhat affected by constitutive influences.

E. B. MILLARD.

Rate of hydration of camphoric anhydride. B. H. WILSDON AND N. V. SIDGWICK. *J. Chem. Soc.* 107, 679-82(1915); cf. *C. A.* 8, 906.—Conductivities of camphoric acid for concns. from 0.0964 to 0.618 milli-mols. at 18° and 25° have been measured by the method previously described. Camphoric anhydride was shaken with H₂O for varying lengths of time in a thermostat, after which the cond. of the soln. was measured. The hydration was complete at 25° in about 2 weeks, at 18° in about a month. Similar expts. in which the anhydride was shaken with 0.005 *N* alkali allowed the "catalytic" action of a base to be calcd. The rate of formation of acid from the anhydride was (approx.) 10000 times greater in the presence of alkali. E. B. MILLARD.

Neutralization curve of boric acid. E. B. R. PRIDEAUX. *Trans. Faraday Soc.* May 11, 1915 (3 pp.) (*advance proof*).—The calcd. points on a diagram plotting $-\log[\text{conc. H}^+ \text{ ion}]$ against the quantity of the first H⁺ neutralized did not fall on the exptl. plot. The deviation was ascribed to the formation of complex borates, since these would cause a difference between the apparent dissociation const., and that of the pure acid. Values recalcd. with a new value for this const. gave too great alkalinity, as would be expected if the degree of complex formation increased as neutralization progressed. E. B. MILLARD.

Problem of complex molecules. I. Evaporation and osmotic pressure. P. LENARD. *Sitzb. Heidelberger Akad. Wiss. Klasse A* 1914, 27, 28, 29, *Abhandlung* 23, 44, 66; *Chem. Zentr.* 1915, I, 930.—L. assumes that the charge on an electrically charged liquid cannot evap. with the fluid. The charged mols., which form large complexes by addition, are unable to evap. Even during the existence of the complex the mols. contained in it are held in the liquid by strong mol. forces as common mols., but the presence of mols. which are unable to evap., causes a depression of the v. p. of the liquid. In solns. the surface is composed of "soln. mols.," i. e., complexes between the simple solute mol. and several mols. of the solvent. From these considerations, the formulas for v. p. of a soln., and osmotic pressure are derived. Mol. forces do not come into consideration, but only the vol. of the complex mols., which accounts for the colligative properties of solns. **II. Molecular forces and their electrical action; waterfall electricity.** From the forces which act on the complex mols. in the surface an expression connecting these with the vol. of the mols., the mass of the active spheres and the temp. has been derived, from which the forces can be approx. calcd. in abs. measure. The rate of formation of surface films on freshly created surfaces could be followed (e. g. in waterfall electricity). Here the surface film consisted of an elec. double layer whose moment was a function of the dielectric const. (*D*) of the liquid. From an equation of Coehn and Raydt (*Ann. Physik* 30, 777, (1910)) according to which the elec. charge on a surface was proportional to the difference between the dielectric const. of the liquid and the gas above it, L. shows that the mol. force is proportional to (*D* - 1) for any liquid. The surface tension was substituted for the mol. force (which cannot be measured) or the inner force, since these in fact are proportional to *D* for CO₂, CCl₄, C₆H₆, CS₂, Et₂O, PhNH₂, PhNO₂ and H₂O. **III. Surface properties of liquids. Position of electrostatic charges. Vapor condensation.** The usual expression for the seat of electricity in extremely small surface films was replaced by a more refined one based on mol. structure. Electrified and unelectrified cloud particles of similar size do not show the large differences in point of condensation which are usually ascribed to them. E. B. MILLARD.

Relations between chemical constitution and crystal structure. P. GROTH. *Z. Kryst. Min.* 54, 498-504(1915); continuation of *C. A.* 8, 2832, 3049.—The chief difference between crystals and amorphous substances (gases, liquids, gels and "amorphous" solids) lies in their thermal properties. As to the uniting of atoms into the crystal structure, in diamond this can be accounted for by the valence of C, but in other

substances it is at present not possible to represent the structure on this basis. In diamond also the arrangement of the atoms corresponds with the cleavage, but in other substances this is not the case, and other phenomena such as cohesion evidently have an as yet undetd. influence. The atom is to be regarded as an anisotropic object, because of the variation in the forces it exerts with the direction; and mols. of amorphous substances, since they contain atoms in definite arrangement, must also be anisotropic; the optical isotropism of these substances is then evidently the result of the irregular arrangement of the mols. The anisotropism of mols. necessitates the exertion of orienting forces between them, which are weaker the less the anisotropism and the greater the mol. wt. The amorphous nature of all the more complicated compds. and certain phenomena of liquid and soft crystals may thereby be accounted for. Crystn. can only occur when at least a part of the constituents of the mols. become rearranged into groups of like atoms. But that certain of the more stable structural features of the mols. exert an effect on the atomic arrangement is shown by the many relations traceable between the chem. constitution and crystal structure, including the phenomena of morphotropy. Examples of these relations, chiefly organic compds., are discussed.

E. T. WHERRY.

Simple gliding (Schiebung) in lithium sulfate monohydrate. A. JOHNSEN. Kiel. *Neues Jahrb. Min. Geol.* 39 (Beil. Bd., Bauer Festschrift) 500-20(1914).—The various methods which have been used for exerting pressure on substances are critically discussed, Tresca's method (1879) being adjudged the most satisfactory, since it permits measurement of the max. one-sided pressure. The crystals of $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ used are described crystallographically, slight differences from the accepted values of the constants being observed. After several unsuccessful or unsatisfactory trials by different methods, crystals were embedded in flowers of S, in a steel cylinder and exposed to as much as 7000 atm. pressure. for some hrs., when the S was dissolved out by CS_2 . "Sublimate," which could be dissolved away by Et_2O , and Wood's metal, which could be melted away at $80-90^\circ$ also gave good results. Gliding was found to take place on $K_1 = (\bar{1}21)$ with $\sigma_2 = ?(012)$. Translation occurred on (100), ($\bar{1}01$), (301), ($\bar{1}01$), and ($\bar{1}21$). By theoretical considerations and soln. expts. it is shown that the mols. of $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ are not enantiomorphous.

E. T. WHERRY.

Artificial translations in magnesium sulfate. A. JOHNSEN. Kiel. *Centr. Min. Geol.* 1915, 33-8.—Translations in 5 directions, all parallel to known growth forms, were found to occur by the method previously described (cf. preceding abstract). The circular polarization was also studied, and crystals with the right bisphenoid (111) were found to be dextrorotatory. Crystals of Sr formate dihydrate showed 3 translation directions.

E. T. WHERRY.

A relation concerning the distribution of an electrolyte between water and some second solvent and its dissociation constant in aqueous solution. H. J. M. CREIGHTON. Swarthmore Coll. *J. Frank. Inst.* 180, 63-74(1915).—The following general formula has been developed for the calcn. of the concn. of the undissoc. mols. of an electrolyte in H_2O , by means of data obtained by the measurement of the distribution of the electrolyte between H_2O and a 2nd liquid phase:

$$z = \left[\frac{c' - c \sqrt{\frac{[b'(1-x') + n\sqrt{b'x'}]}{[b(1-x) + n\sqrt{bx}]}}}{\frac{[b'(1-x') + n\sqrt{b'x'}]}{[b(1-x) + n\sqrt{bx}]} - \sqrt{\frac{[b'(1-x') + n\sqrt{b'x'}]}{[b(1-x) + n\sqrt{bx}]}}} \right];$$

where z is the concn. of the undissoc. mols. in the aq. phase, c and c' are total concns. of the solute in the aq. phase in normal mols. per liter, b and b' are total concns. of the solute in the 2nd phase in normal mols. per liter, x and x' are degrees of association

of the solute in the 2nd phase for the 2 concns. b and b' , and n is the complexity of the associated mols. in the 2nd phase. In order to test the validity of this formula, measurements of the distribution of benzoic acid between H_2O and C_6H_6 have been carried out at 6° , and, from the data obtained, the concn. of the undissoc. mols. of C_6H_5COOH in the aq. phase has been calc. From these values, a mean value, 7.21×10^{-3} , has been obtained for the dissoc. const. of C_6H_5COOH in H_2O at 6° . Although the foregoing value for the dissoc. const. of C_6H_5COOH in H_2O is somewhat higher than that obtained by the cond. method, the use of the distribution method for obtaining an approx. value for the dissoc. const. of an electrolyte, in those cases where the value as detd. by the cond. method varies considerably with dilution, is suggested. H. J. C.

New method of determining solubility at different temperatures. L. A. CHUGAEV AND V. G. KHILOPIN. *J. Russ. Phys. Chem. Soc.* 46, 1659-68(1914).—The usual methods of detg. solubility at different temps. require the use of a thermostat and a special arrangement for continuous stirring. C. and K.'s method avoids the use of these. It consists in detg. the solubility of substances at the b. p. of their satd. solns., the desired temps. being obtained by varying the pressure, while the thorough mixing of the materials is insured by vigorous boiling. A suitable app. for this purpose consists of a wide-mouthed boiling flask in which the soln. is boiled with an excess of the solute, the temp. being indicated by a delicate thermometer, while the desired degree of rarefaction is effected by connecting the flask with a pump. In the upper part of the flask is suspended a weighing tube which can be filled with the satd. soln. by means of a syphon reaching to the bottom of the flask. Cuts of the app. and its parts are given. The solubilities of Li_2CO_3 , CaO , KNO_3 , $KClO_3$ and NH_4Cl were detd. by the new method, and the results found to compare very favorably with the best data given in the literature. H. M. GORDIN.

Solubility of strontium sulfate in solutions of calcium salts. M. RAFFO AND G. ROSSI. *Gazz. chim. ital.* 45, I, 45-50(1915).—The authors detd. the solubility of $SrSO_4$ (pptd. in the soln.) in aq. solns. of $Ca(NO_3)_2$ in various concns. It increases from 0.0483 g. per cc. for 0.5% $Ca(NO_3)_2$ solns. to 0.1955 g. for a 6% soln. The solubility of $BaSO_4$ in H_2O was not affected by the presence of $CaCl_2$ or $Ca(NO_3)_2$. The above gravimetric results were confirmed by elec. cond. measurements. E. J. W.

Vapor pressures and specific volumes of binary mixtures of volatile with non-volatile liquids. F. H. CAMPBELL. *Trans. Faraday Soc.* May, 11, 1915 (11 pp.) (advance proof); cf. C. A. 9, 402.—C. has made detns. of the sp. vol. and v. p. of mixts. of oleic acid and ether, oleic acid and CS_2 , $C_6H_5NH_2$ with Et_2O , oleic acid and acetone, Et_2O and H_2SO_4 , $MeOH$ and glycerol, and H_2O with glycerol, using the method worked out before. The results may be adequately explained on the assumption that the form of vapor pressure curve is detd. by mol. changes accompanying the process of soln. Thus the soln. may consist of a smaller number of particles than the liquids constituting it did before mixing, as a result of solvate formation, or the number may be greater owing to the dissociation of an associated liquid. Probably the most common case is where both processes take place together. Attempts to apply Dolazalek's theory quantitatively were not successful, even in the simplest cases. C. has suggested that the abnormal behavior of some pairs of liquids may be due to the formation of volatile complexes, *i. e.*, hydrates. E. B. MILLARD.

Equilibrium in the systems: α -naphthylamine-guaiacol and urethan-benzene. N. A. PUSHIN AND G. N. MAZAROVICH. *J. Russ. Phys. Chem. Soc.* 46, 1366-72(1914).—An exam. of the fusion diagram of mixts. of α -naphthylamine and guaiacol (a) showed that the system contains a definite compd. $C_{10}H_7(OH)(OMe).C_{10}H_7NH_2$, m. 21.4° , and 2 eutectics (e), at 40 mol. % of a and 19.8° , and at 77 mol. % of a and 14.3° . Only in the interval 43-50 mol. % of a are solid solns. probable. In the system urethan-

C_6H_6 (b) there is an ϵ at 97 mol. % of b at 4.2° , and solid solns. in the interval 97–100 mol. % of b . The existence in this system of such solns. accounts for the fact that the mol. depression of the f. p. of b caused by dissolving urethan in it is considerably smaller than the calcd. value (35.4 and 29.9 as found in 2 expts. against 51 given in Landolt-Börnstein's tables).

H. M. GORDIN.

Contact action of water vapor and carbon in the oxidation of ferrous compounds. A. G. DOROSHEVSKII AND A. YA. BARDY. *J. Russ. Phys. Chem. Soc.* 46, 1669–76 (1914).—Continuing the work on the oxidation of alcs. in presence of C containing FeO salts (C. A. 9, 1865), D. and B. examd. the influence of H_2O vapor on the catalytic power of C. For this purpose samples of C were mixed with $Fe(CO)_5$ and the mixts. divided into groups, some being kept in presence and others in absence of H_2O vapors, the temp. in both cases being about 18° . From time to time the samples were extd. by digestion with 10% H_2SO_4 , and the amt. of unchanged ferrous salt detd. with standard $KMnO_4$. It was found that oxidation of the ferrous salt took place only in presence of H_2O . Expts. were also made in order to det. the influence of temp. in this reaction by making similar detns. at 39 – 41° . The results showed that a rise in temp. greatly accelerated the oxidation. Since the previous expts. proved that the oxidation of alcs. in presence of C depends upon the latter containing FeO salts, C containing H_2O slowly loses its activity as an oxidizing agent upon prolonged keeping. If the time in the expts. at the 2 temps. be plotted against the amts. of unchanged FeO salts, it will be found that C containing the latter and H_2O will "die" as an oxidizing agent within a few days if kept at a moderately elevated temp., while at ordinary temp. its "span of life" is a few months. Unlike its oxidizing power, the adsorbing power of C seems not to be influenced by H_2O , a variation of 0.5–2.08% of H_2O having no effect on the adsorbing power. Experimenting with $FeCl_3$, it was found that shaking it with C and dil. H_2SO_4 greatly accelerates the oxidation (by the O from the air or from the C). The extn. of the above samples with H_2SO_4 was therefore made by digestion without shaking. The accelerating effect of shaking can hardly be ascribed to greater intimacy of contact between the materials. Taking into consideration the reducing effect on Fe_2O_3 salts, accompanied by an evolution of CO_2 , it can be seen that a mixt. of C and Fe actually "lives": it absorbs O from the air, changing FeO to Fe_2O_3 , and exhales CO_2 , causing the reverse reaction. As in other life phenomena, both processes require the presence of H_2O .

H. M. GORDIN.

Reaction velocity in a viscous (heterogeneous) medium. R. H. CALLOW. *Trans. Faraday Soc.* May 11, 1915 (5 pp.) (advance proof).—The hydrolysis of MeOAc by NaOH and by HCl at 18° has been studied in the presence of various amts. of gelatin added to produce a change of viscosity. No velocity const. were obtained from the alkaline hydrolysis, since the gelatin reacted with NaOH. If the gelatin was previously neutralized, its Na salt hydrolyzed on dilution with MeOAc. The relative viscosities as detd. in a Scarpa viscosimeter were 1.48, 3.69, 8.98, and 20.3. A series of reaction const. was obtained which showed a diminution as the gelatin concn. increased, but for a large change of viscosity there was a comparatively small change in the velocity const. Even in a set jelly the const. was only 10% less than when no gelatin was present.

E. B. MILLARD.

Physico-chemical kinetics. II. R. MARCELIN. *Ann. phys.* 3, 185–231 (1915); cf. C. A. 9, 1710.—A physico-chem. complex in the process of transformation consists of a progressive system (of increasing mass) and a regressive system (of decreasing mass), such that the observed speed of the "reaction" is the resultant of these 2 systems. This idea was applied to the derivation of formulas for velocity of diffusion, crystn., soln., evapn., etc. From expts. on the speed of evapn. of Et_2O , CS_2 , $C_6H_5NO_2$, $C_{10}H_8$, and I, M. concludes that a liquid in contact only with its vapor may be overheated

while the pressure of the vapor is still 7 to 8 mm. Hg less than that of satd. vapor. In capillary tubes about 3 mm. in diam. the speed of evapn. when the liquid was overheated was $V = K(T_B - T_P)/rdL$, where K was a known const., T_B the temp. of the thermostat surrounding the tube, T_P the temp. at which vapor and liquid existed in equil. at the pressure P of the expt., d the density of the liquid, L its latent heat of evapn., and r the radius of the tube. The expts. showed that the temp. of the surface of an evapg. liquid was not that of the body of liquid, but that it corresponded closely to T_P , the equil. temp., and that the observed speed of evapn. was proportional to the rate of heat flow from the interior to the surface of the liquid. Expts. on the speed of sublimation of I and $C_{10}H_8$ into a vacuum showed that the speed of sublimation increased very rapidly with the temp.; e. g., from 0.0002 to 0.0165 arbitrary units from 35° to 70° . E. B. MILLARD.

Substances possessing anomalous dispersion of rotatory power. I. G. BRUHAT. *Ann. Phys.* 3, 232-82(1915).—Description of app. and methods to be used in later work. E. B. MILLARD.

Kinetics of chemical reactions. X. E. I. ORLOV. *J. Russ. Phys. Chem. Soc.* 46, 1441-81(1914); cf. *C. A.* 6, 1247; 7, 1123, 3063, 3064, 3065, 3563; 8, 3144.—An exam. of the work of Millar (*C. A.* 8, 449) showed that the velocity const. given in his tables gradually diminishes as the reaction progresses. This is due to M. having used in his calcns. the usual formula for monomol. reactions which, as was shown by O. in several articles, is in many cases inapplicable on account of intermediate reactions, making the reaction more complicated than is assumed in that formula. If O.'s formulas be used the agreement between theory and expt. is very good; this is shown by recalculating M.'s tables on the basis of these formulas. The intermediate reactions in M.'s work may consist in the formation of various complexes which are discussed at great length. It is assumed that the ions of the catalyzer (picric acid) distribute themselves between the components of the mixed solvent (alc. and H_2O) according to the law of mass action, forming various solvates. For calcg. the distribution of the H ions of the catalyzer between an alc. and H_2O , the decomp. of esters of diazoacetic acid:

esterification of an alc., because in the 1st case the reaction is not reversible, while in the 2nd the reversibility of the reaction furnishes additional H ions coming, not from the catalyzer, but from the acid. Hence the nature of distribution will vary with the nature of the acid. This is corroborated by an exam. of Goldschmidt and Thuesen's work (*C. A.* 7, 1651). Numerous tables and curves illustrate the article. H. M. G.

The effect of mechanical vibration on carbon dioxide in the vicinity of its critical temperature. W. P. BRADLEY, A. W. BROWNE AND C. F. HALE. *Z. Anorg. Stöckst.-Ind.* 6, 77; *Chem. Tech. Rept.* 38, 370(1914).—In the course of expts. on the critical state of CO_2 it was observed that shaking the pressure tube, which contained CO_2 in both liquid and gaseous phases, caused a nebulous appearance within. Although this phenomenon is a familiar one it has usually been considered the result of thermal change. The authors found that the nebula was formed only when the tube was held vertically and that the vibration of a tuning-fork dissipated it. The resulting expansion was exceedingly slight. H. L. OLIN.

Thermochemical significance of the coefficient "i" in $PV = iRT$. A. BOGORODSKI. *J. Russ. Phys. Chem. Soc.* 46, 1716-34(1914).—The coeff. i in van't Hoff's equation was introduced for the purpose of explaining the abnormal behavior of electrolytes in soln. in respect to elec. cond., lowering of f. p., etc. The explanation consists

in the assumption of electrolytic dissociation into ions caused by the solvent. Since, however, Khrushchev (*Ibid* 34, 153(1902)) showed that different salts exhibit strict individuality in that for some of them i increases, for others decreases, and for still others remains const. upon diln., the electrolytic dissociation hypothesis does not satisfactorily explain the nature of i . B. proposes therefore a new theory of soln., regarding the latter as a particular kind of hydrolysis. According to this the soln. of salts in H_2O consists in converting them into systems of $M(OH)_n(H_2O)_x$ and $RH_n(H_2O)_y$ (M = metal, R = acid radical). Part of these complexes are united with each other, forming the undissociated part of the salt, while another part is in equil. with solvent. To the latter part are due those properties of solns. which are usually ascribed to ions. From this point of view the heat of neutralization is the heat of formation of the hydrolyzed but undissociated part of the salt. If C_2 is the heat of formation of the dissociated part, and C_1 the heat of formation of the whole salt, C_2 will be equal to C_1 minus the heat of neutralization, and the ratio C_2/C_1 will have the same meaning as P_1/P for osmotic pressure and, in general, as the coeff. of dissociation i . Detg. the values of i thermochem. and cryoscopically, they were found to be almost identical, the ratio between them being from 1 to 1.1 in 28, and from 1 to 1.05 in 22 expts. This concordance entitles the theory to consideration.

H. M. GORDIN.

Heating method in investigating binary eutectic mixtures, particularly those containing silicates. N. I. BEZBOROD'KO. *J. Russ. Phys. Chem. Soc.* 46, 1830-74(1914).—The usual method of examg. binary systems of solids with respect to their eutectic and other singular p. consists in observing the p. of crystn. after the systems had been liquefied by fusion. This method presents great difficulties when the components show the phenomenon of supercooling, or when they dissociate under the influence of the high temp. to which mixts. have to be heated. B., therefore, proposes to use the method of gradually heating the mixts. instead of gradually cooling the melts. The m. p. gives as reliable data as the congealing p., and since in this method high temps. are avoided, the above drawbacks are eliminated. The applicability of this method to several systems is proved by numerous expts. in which were included several silicates of the contact-metamorphous variety (Memoirs of the Novoch. Technol. Inst., 1913, 101) which are characterized by ready dissociation. Microscopic examns. of melts obtained by this method are promised for a future date. Numerous tables and curves illustrate the expts.

H. M. GORDIN.

Vapor pressure of concentrated sugar solutions. D. O. WOOD. *Trans. Faraday Soc.* May 11, 1915 (19 pp.). (*advance proof*).—Solns. contg. 92.0, 156.6 and 224.3 g. sucrose per 100 g. H_2O were introduced into a special app. and freed from all traces of air, after which the vapor pressures were detd. barometrically. During the expts. the solns. were stirred by a glass float contg. Fe bars by means of an exterior electromagnet. Detns. of the v. p. of H_2O for every 5° from 60° to 90° agreed with the data in Landolt and Börnstein to about 3 mm. only. The heat of diln. of the weakest soln. as calcd. from the v. p. measurements increased with the temp.; for the stronger solns. it decreased with rising temp., but all of the values were of the right sign and order. Osmotic pressures calcd. from the v. p. data showed a decrease with rising temp. "While it was probable that the real pressure did not diminish, yet it certainly changes very slowly with the temp. for these strong solns."

E. B. MILLARD.

Heat of vaporization and molecular association in liquids. M. M. GARVER. *J. Phys. Chem.* 19, 500-12(1915).—Reply to Tyrer (*C. A.* 9, 993) defending the papers of C. A. 6, 1697 and 2879 against T.'s criticism. The equation discussed is $\gamma/2\epsilon = \rho RT/m$, where γ is the surface energy in dynes per cm. length, ϵ the range of mol. action, ρ the density of the liquid, m the mol. wt. of the vapor and R and T have the usual meaning.

E. B. MILLARD.

Calculation of the Despretz-Trouton constant. D. BERTHELOT. *Compt. rend.* 160, 637-60(1915).—The value of Q/T , where Q is the latent heat of vaporization and T the abs. temp., as calcd. from the integral of the equation $Q = \int_{T_1}^{T_2} (a/v^2) dv$, with the help of van der Waals' equation, was only 9 cal., in place of the usual 20 or 22. If the Berthelot equation be used in place of the van der Waals equation, the value 18 cal. may be obtained, making the same assumptions as before. E. B. M.

Von Babo's law and Kirchhoff's equation for the latent heat of dilution. A. W. PORTER. *Trans. Faraday Soc.* May 11, 1915 (10 pp.) (*advance proof*).—The equations have been derived thermodynamically proceeding as far as possible without any assumptions and without dropping "negligible" quantities which become considerable as the critical point is approached. The mathematical treatment cannot be briefly abstracted. E. B. MILLARD.

The calorimetric bomb and the heat of combustion of benzoic acid. V. SVYENTOSLAVSKII AND M. POPOV. *J. Russ. Phys. Chem. Soc.* 46, 935-75(1914).—In order that different investigators obtain concordant results in working with calorimetric bombs, it is necessary that they should all use as standard the heat of combustion (H) of the same substance, and that the detn. of the consts. of the app., the corrections, etc., should be made by the same method. The most suitable substance for use as standard is $BzOH$ (B). Since for the H of B different values are given in the literature, it is important to state in each case what value of H was used. This value, as detd. by the very careful measurements of S. and P., is 6310 cal. per g. (abs.) at 17° . The detn. of H for any substance should be carried out under exactly the same conditions as prevailed during its detn. for B . The only correct method for calcg. the H_2O value of a bomb is that of Stohmann (*J. prakt. Chem.* 39, 532). Contrary to the opinion of Fischer (*Ber. Berlin. Acad.* 1904, 687), it is immaterial whether H is expressed in abs. units or in cal. The mass of mathematical details for calcg. the various factors and corrections cannot be abstracted briefly. H. M. GORDIN.

Adiabatic determination of the heat of combustion of benzoic acid. V. SVYENTOSLAVSKII, M. POPOV AND I. PAKOVICH. *J. Russ. Phys. Chem. Soc.* 46, 1293-301(1914).—In a former investigation (cf. preceding abstr.) the heat of combustion (A) of $BzOH$ detd. non-adiabatically was found to be 6310 cal. for 1 g. (abs.). Detg. A adiabatically in their new calorimeter (cf. *C. A.* 9, 2165), its value was found to be 6304.6 cal. per g. (abs.). The occasion was used to give the new app. a thorough trial. The numerous expts. given in tables and curves showed that for this calorimeter the temp. changes for the calorimeter proper and its jacket are represented by curves that practically coincide, proving that there is practically no loss through radiation. H. M. GORDIN.

Regnault-Pfaundler's formula. V. SVYENTOSLAVSKII. *J. Russ. Phys. Chem. Soc.* 46, 1302-10(1914).—Comparing the values of the heat of combustion of $BzOH$ detd. adiabatically in the new calorimeter and non-adiabatically in a Berthelot calorimeter, it was found that the value by the 1st method is lower by 1% (cf. the 2 preceding abstrs.). The reason of this is that the correction for the heat of evapn. of H_2O on the surface of the calorimeter is omitted in Regnault-Pfaundler's formula, evidently assuming that the loss due to this source is proportional to the difference in the temps. of the calorimeter proper and its outer shell. It is shown that when this source of error is eliminated by covering the calorimeter with kerosene the 2 methods give identical results. H. M. GORDON.

New method for determining the specific heats of liquids. E. J. HARTUNG. *Trans. Faraday Soc.* May 11, 1915 (5 pp.) (*advance proof*); *C. A.* 9, 405.—A thin glass bulb contg. a large roll of Ag gauze and 3 or 4 cc. of H_2O was dipped in Hg at -4°

until the water was frozen. It was then quickly hung in a basket on the stirring rod of a small calorimeter contg. 60 cc. of the liquid under investigation. The Ag gauze caused rapid melting of the ice, and the minimum temp. was soon obtained. Thomsen's data on dil. H_2SO_4 agreed well with those obtained by this method. The new detns. were on organic liquids between 17° and 20° as follows: MeOH 0.591, EtOH 0.564, Et_2O 0.541, CS_2 0.234, $\text{C}_6\text{H}_5\text{NH}_2$ 0.472, and $\text{C}_6\text{H}_5\text{NO}_2$ 0.342. E. B. MILLARD.

Determination of the specific heats of fluids. A. HEYDWEILLER. Rostock. *Ann. Physik* 46, 253-60(1915).—Two bodies of fluid, an unknown and a standard, are heated by the same elec. current, and the temp. rise in each compared (Pfaundler's calorimeters.) Two quartz-glass inclosed Pt coils are used, each serving alternately for heater and resistance thermometers in each calorimeter. Owing to methods of transposing the fluids, etc., the effects of lack of symmetry between the two calorimeters are largely eliminated in the results. Each calorimeter consists of two Dewar tubes, one inclosing the other. The inner has only 2.4 cm. internal diameter, and both are closed by corks. Very small quantities of fluid can thus be investigated. In the example given, 20 cc. were used. Very high precision apparently was not sought, since an ammeter was used to read the current. W. P. WHITE.

The ratio of the specific heats of gases for constant pressure and for constant volume at different pressures. K. SCHÖLER. Kiel. *Ann. Physik* 45, 913-28(1914).—The method of the "Kundt's tube" for measuring the wave velocity in gases had been modified to permit using sealed tubes by Behn and Geiger, who altered the vibration period of the tube by weighting the end. Keutel and Thibaut, using this method, had observed a surprising variation of $k = c_p/c_v$ with pressure, for CO_2 and SO_2 , and at pressures ($1/3$ atm. to 1 atm.) where the condition of an ideal gas is usually supposed to be practically reached. The present investigation extends the pressure range from $1/3$ to 3 atm. (usually) and tests other gases. The gases were at 20° . For air, which was far above crit. temp. and pressure, the variation in k was 5 per mille. For CO_2 (crit. temp. 31°) it is 15 per mille. For C_2H_4 (crit. temp. 11°) it is 46 per mille, for SO_2 (crit. temp. 155°) 57; for NH_3 (crit. temp. 131°) 83. S. divides the gases into 3 groups: air, which is far above its crit. temp.; CO_2 and C_2H_4 , which are near their crit. temp. but far from being condensed; and SO_2 and NH_3 , which are near condensation and below their crit. temp. But C_2H_4 , as his data show, has values of k nearer those of SO_2 and NH_3 . W. P. WHITE.

An exponential temperature scale. R. H. WEBER. Rostock. *Physik. Z.* 16, 9(1915).—In order to establish his claim to priority the author repeats a notice published 2 years before. His suggestion, which he says is more instructive than practical, is to substitute for the ordinary definition of a degree of temp.—namely, an increase in temp. which causes a perfect gas to increase by a given fraction of its volume at zero—the definition that a degree is an increase in temp. which causes a gas to increase by a given fraction of its volume *at the temperature in question*. The length of the degree thus increases with temperature, as compared to the usual system. For a centigrade scale in the new system 500° is 371.54° , and the absolute zero becomes $-\infty$. W. P. WHITE.

Conductivity of metals. J. J. THOMSON. *Engineering* 99, 577-9(1915).—The arguments for and against the theory that conduction in metals was due to the motion of electrons have been collected into this lecture. The conds. could not be explained without assuming within a metal the presence of more electrons than were in accord with its other properties, though the transport of electricity by heat and contact differences of potential could be nicely accounted for by the electrons. The expts. of Kammerlingh Onnes with super-conductors quite put an end to the electron theory, since neither the number of electrons nor their velocity could be conceived to increase as the temp.

was lowered. A Grotthus chain theory of metallic conduction was also mentioned.

E. B. MILLARD.

Thermal electromotive forces of iron oxide and copper oxide. S. L. BROWN AND L. O. SHUDDEMAGEN. Univ. of Texas. *Physic. Rev.* 6, 385-89(1915).— Fe_2O_3 , CuO , and Cu_2O were investigated. CuO was formed by oxidizing a Cu wire, the others by fusing a higher oxide. Cu_2O decomposes into CuO and Cu when cooled to about 800° , but can be obtained cold by cooling very rapidly through 800° . The authors' Cu_2O , however, was found to contain 1.5% of CuO . Fe_2O_3 was neg. to Fe, with a thermoelectric power of 427 microvolts per degree, which was nearly const. up to 725° . The 2 Cu oxides were both positive; Cu_2O to Cu gave 1037-0.75 (θ —20) microvolts; CuO to Cu was higher still. The authors state that their values are much higher than obtained by others, but do not say how much. They suggest a difference in physical state, due to the method of prepn., as a possible cause.

W. P. WHITE.

Determination of the value of "e" by Millikan's method. J. Y. LEE. *Phys. Rev.* 4, 420-34(1914).—A physical investigation in which the mean value of "e" (the elementary elec. charge) was detd. to be 4.764×10^{-10} electrostatic units.

E. B. MILLARD.

Electric charges and Brownian movement of very small metallic particles in gases. Contribution to the question of an elementary quantum of electricity. D. KONSTANTINOWSKY. *Ann. Physik* 46, 261-97(1915).—The particles of Au and Hg were so small that the characteristic color of the optical resonance was visible. Au particles showed yellow-red, orange, yellow and green, Hg was azure blue. The exptl. method and general argument are similar to those of Ehrenhaft (*C. A.* 8, 1050, 3262). It was shown that the particles were spherical in 3 different ways, so that the application of the Stokes-Cunningham equation was safe. As a result of the expts., K. claims that "the existence of an ultimate elementary quantum of electricity of a lower order of magnitude than that found by Ehrenhaft is possible." The charge of "2 electrons" must be distributed over at least 17 particles, even from calcns. based on the Brownian movement, which are certain to give high values. Even a charge of 0.1 of the elementary quantum may be distributed over 17 particles.

E. B. MILLARD.

Determination of N_e for hydrogen from measurements of Brownian movement. C. F. EYRING. *Phys. Rev.* [2] 4, 412-17(1915).—Using the app. of Fletcher (cf. *C. A.* 9, 1413), and his extension of the Brownian movement, a detn. of $N \times e$ has been made. (N is Avogadro's number and e is the charge on an ion). The value obtained was $2.880 \times 10^{14} \pm 0.5\%$. The expts. show that this method may be applied to gases other than air, and that the ions of ionized H carry the same charge as the H ion of electrolysis. ($N \times e$ from electrolysis is 2.896×10^{14} .)

E. B. MILLARD.

Electromotive force of calcium amalgams. LIVIO CAMBI. Milan. *Atti accad. Lincei* 23, II, 606-11(1914).—Local soln. of the electrodes was prevented by using Ca amalgams as electrodes in a MeOH soln. of CaCl_2 at -80° . The amalgams were kept 78-100 hrs. at 220° before use. The solns. during the measurements were kept in a dry atm. of H. The compensation method was used in making the measurements and a Cd normal cell was used. The opposite electrode was a calomel electrode in MeOH at 25° , having an abs. e. m. f. of 0.288 v. The chain

has an e. m. f. of -0.070 v., from which 0.358 v. was calcd. for the cooled electrode. It was thus possible to det. the e. m. f. of various Ca amalgams by using chains

—80°

The e. m. f. values thus detd. plotted as a function of the concn. show a rise of 0.2 v. when the electrode is CaHg_y . Thus the existence of this compd. is proved electrochemically. A 2nd rise indicates the presence of the compound CaHg , which was not demonstrated thermally, possible because its temp. of formation was too near the eutectic temp. It is also possible that anomalies in the e. m. f. may be due to surface layers.

E. J. WITZEMANN.

Hall effect in tellurium-bismuth alloys. G. C. TRABACCHI. Rome. *Nuovo cimento* 9, 95-8(1915).—T. detd. the Hall effect in Te-Bi alloys ranging from 0 to 100% Te, and on plotting the results, obtained a curve resembling fairly closely the curve of thermoelectric force found by Haken for the same series of alloys. Now, considering the curve of fusion of the same series, it is probable that there is an intimate relationship between the Hall effect, the thermoelectric power, and the structure of the conductor.

S. LEVY.

A possible explanation of the Hall and Ettingshausen phenomena. EDWIN H. HALL. Firinze. *Nuovo cimento* 9, 5-12(1915).—The conception of a current in a metal as a movement of negative electrons alone, offers many difficulties in explaining the Hall and Ettingshausen phenomena. With this conception must be combined the idea of a movement of electrons from atom to atom, and from a normal atom to one with + charge, rather than between 2 normal atoms, as in this latter case the new condition (the presence of a + atom and a - atom in juxtaposition) would tend to recreate the normal atoms. It is evident then that the number of + atoms, or ions, is the same as the number of free electrons at every point of the metal. The movement of normal atoms does not produce an elec. current. The movement of free electrons takes place in one direction, and in an opposite direction for a limited distance, the movement of the + ions. With an elec. current passing from left to right in a metallic plate in a magnetic field (supposing this to be directed upwards) the free electrons and the vibrating ions are subjected to the new force. The electrons are mechanically free to yield to the force, but the ions can only undergo a change in the direction of their vibration. This action constitutes a + current upwards tending to reproduce a + charge; but the movement of the electrons upwards tends to produce there a - charge. If the tendency of the ions is stronger than that of the electrons, we have a + charge above (the case in an Fe plate); the opposite case is that of a Ni plate. In metal plates subject to these effects there is a const. process of dissociation of neutral atoms into electrons and ions at one part, and a re-association to form neutral atoms at another part. The force carrying the electrons and ions in one direction is electromagnetic, the force carrying the neutral atoms in the other direction is elastic-mechanical. There must be at the same time a distribution of thermal velocity among the free electrons of a metal. The slow electrons, i. e., the cold ones, are subject for a longer time to the elec. influence maintaining a current, which, as far as it is due to free electrons, is really a progressive movement of cold electrons. The dissociation of neutral atoms increases with the temp., and is accompanied by an absorption of heat; there exists then a latent heat of dissociation of the atoms. The movement of cold electrons towards the top (as in Fe) tends to cool that part of the plate, and to give rise to a reassociation of electrons and ions. This would explain the Ettingshausen effect in Fe. If the increase of temp. due to reassociation is stronger than the cooling tendency of the cold electrons, we have the Ettingshausen effect as it is in Sb. The same mode of consideration will explain the Hall and Ettingshausen effects in Ni.

S. LEVY.

The temperature coefficient of photochemical reactions. DANIEL BERTHELOT. *Compt. rend.* 160, 440-3(1915).—The velocity const. of an ordinary chem. reaction increases with temp., in general, according to an exponential law. For ordinary temps. the temp. coeff. of the reaction, $K_t + 10/K_t$, has a range from 2 to 3. Photochem. reactions, however, are little influenced by temp. The velocity of decompn. of levulose by ultraviolet light showed a temp. coeff. of 1.035 between 40 and 70°. A soln. of $C_4H_2O_4$ and $FeCl_3$ showed a temp. coeff. 1.01 between 21 and 61°, agreeing with Lemoine's detns. between 3 and 35°. The frequency of the exciting radiation plays the rôle in photochem. reactions that temp. plays in ordinary reactions. Thus the photochem. combination of Cl and H is slow for red light, rapid for yellow light, and explosive for violet light, while the chem. combination of O and H is imperceptible at room temp., very slow at 200°, fairly rapid at 500°, and explosive at 850°.

PAUL D. FOOTE.

Quantitative absorption spectra. I. Chemical significance of absorption spectra and the methods of examining them. F. R. LANKSHEAR. *Mem. Proc. Manchester Lit. Phil. Soc.* 58, No. 15, 12 pp.(1915).—Preliminary paper in which the Hartley method and the Hilger method are described. Somewhat arbitrary specifications are given for app., source of light, solvent, etc., and some of the general characteristics already known are mentioned again. Further work is promised. E. B. MILLARD.

Fluorescence and resonance radiation of sodium vapor. R. J. STRUTT. *Proc. Roy. Soc. London (A)* 91, 388-95(1915); cf. *C. A.* 9, 1269.—The centers emitting resonance radiation of Na vapor excited by the D-lines were not persistent enough to be carried along when the vapor was distd. away from the place of excitation. This was in contrast with the behavior of electrically excited Na vapor and with Hg vapor under either kind of excitation. Even a layer of Na vapor which was quite transparent to white light would not allow Na resonance to pass through. The resonance radiation was changed when the vapor was placed in a magnetic field, being diminished with increasing field strength if the flame was weakly salted, and increasing to a max. and then diminishing if the flame was strongly salted. A change was also observed when the exciting flame was placed in the magnetic field. All of the phenomena observed can be explained by taking into account the known Zeeman resolution of the D-lines and the observed width and structure of these lines as emitted by the flames used.

E. B. MILLARD.

Absorption spectra of the isomerides of ammonium *d*- α -bromocamphor- β -sulfonate. J. E. PURVIS. *J. Chem. Soc.* 107, 643-4(1915); cf. *C. A.* 8, 1416, 2367, 3025; 9, 207.—The 2 isomerides had the rotations: $[M]_{441} = 371^\circ$ and $[M]_{441} = 176^\circ$. Equimolar solns. of camphor and of *d*-camphoroxime were also examined for comparison. Alc. solns. were examd., using the Mo-U arc as a source of light. The sulfonates showed no difference either in their general or specific absorptions. In camphor and the oxime the camphor band was much wider and stronger than that of the sulfonates, and there was also a greater shift toward the red in the case of the heavier sulfonate mols. It was suggested that the CO group was the primary oscillation center, since camphoroxime has no soln. band and is very transparent. The final adjustment is influenced by the other atoms and groups in the mol., as was shown by the camphor bands becoming narrower in the sulfonates.

E. B. MILLARD.

Absorption spectra of the vapors and solutions of anisole, phenetole, and various derivatives. J. E. PURVIS. *J. Chem. Soc.* 107, 660-7(1915); cf. preceding abst.—The vapor bands of *p*-bromoanisole were more diffuse in appearance and fewer than those of anisole. Phenetole had a large no. of bands comparable with those of anisole; *p*-fluorophenetole and, to a greater extent, *p*-bromophenetole, showed a decreased number of vapor bands, those of the latter being more diffuse in appearance. Many of the

bands were absent from the solns., others were changed in character. Anisidines and phenetidines showed no narrow vapor bands, and the soln. spectra were similar to the vapor spectra. The larger soln. bands of *p*-azoxyanisole and *p*-azoxyphenetole than those of azoxybenzene, and the substitution in all the substances at higher temps. and pressures of all the fine vapor bands by wide and diffuse bands which were comparable with soln. bands were also mentioned. The solvent produced an association of the mols. whereby the vibrations were partly neutralized and partly exercised against this constraining force. The introduction of an aliphatic group in phenol does not alter the type of absorption in phenol, but Br or Cl cause a decrease in the number of finer bands.

E. B. MILLARD.

Distribution of energy in the radiation from the uviol-glass lamp. A. J. ALLMAND. *J. Chem. Soc.* 107, 682-8(1915).—The method used was that of Ladenburg (*Physik. Z.* 5, 525(1904)). For uviol A glass the intensities referred to the blue line γ 436 μ were as follows: 571 μ 0.27, 541 μ 0.73, 405 μ 0.56, 362 μ 0.41, and 313 μ 0.17; and for uviol W those measured were 405 μ 0.29, 362 μ 0.25, and 313 μ 0.045. For quartz the corresponding distribution, referred again to λ 436 μ as unity was: for 571 μ , 2.63, 541 μ 3.93, 405 μ 0.54, 362 μ 1.83 and 313 μ 1.28. The velocity coeffs. of photochem. reactions under the influence of the last 3 wave lengths, then, bear the relations 2.2, 4.3, and 4.4, resp., to those when 436 μ was used.

E. B. MILLARD.

Variations in the magnetic double refraction of iron with changes in the temperature. L. TIERI. *Atti accad. Lincei* 24, I, 330-5(1915).—Majorana (*Ibid* 12, I, 463) has stated that there are 3 types of magnetic double refraction in colloidal Fe: (1) positive, (2) negative and (3) a positive double refraction with weak fields which is converted into a negative effect on strengthening the field. T. found that by varying the temp. in each case with each specimen on colloidal Fe all 3 types of refraction were obtained with the same specimen. This variation in the effect is ascribed to changes in the size of the particles.

E. J. WITZEMANN.

Experiments on the nature of transmitted light action in crystals of selenium. F. C. BROWN. *Phys. Rev.* [2] 4, 404-11(1915); cf. *C. A.* 9, 1424, 1427-8. —Light falling on one part of a Se crystal produced a change in cond. in another part. No matter how much the resistance at one end of a crystal might change on account of pressure, the resistance at the other end did not change. Change of resistance on account of change of potential also was not transmitted to another part of a crystal, though the resistance was increased 10 times in the first place. Increase of pressure increased the light sensibility only when the pressure was applied to the part whose cond. was being measured. Then if elec. conduction in these crystals is due to free electrons that exist in equil. according to the law of Maxwell-Boltzmann, it cannot be possible that increasing the mechanical pressure increases the number of free electrons when the cond. is increased, since the pressure effect was not transmitted. The conclusion seemed unavoidable that elec. conduction in Se cannot be due to the traditional free electrons.

E. B. MILLARD.

Theory of cold light. W. D. BANCROFT. *Trans. Illum. Eng. Soc.* 10, 289-95 (1915).—The Moore light is very likely not due to temp. radiation but to chem. reactions; this conclusion is based on B.'s expts. (cf. *C. A.* 8, 1903, 2103; 9, 167, 404, 1573). The bulk of the light in salt flames is due to chem. reactions and not to temp. radiation. To obtain cold light one must find a reaction which can be made to go rapidly, which absorbs heat (or evolves only a small amt. of heat) and which has a high conversion factor for light.

Alkaline earth selenides with phosphorescent properties. FRITZ KITTLEMAN. *Ann. Physik* 46, 179-96(1915); cf. Pauli, *C. A.* 6, 826.—Prepn. of some of the sub-

stances which Pauli had not made. Curves are given showing the emission bands of several of the compds. contg. Ca, Sr or Ba with Se and a heavy metal. All of the bands are between 700 and 500 μ , with bands in the visible violet or ultraviolet totally absent. With the same heavy metal in the 3 alkaline earth selenides the emission was shifted toward the longer wave lengths for increasing at. wt. Mn was an exception. Thus the max. was shifted 57 μ from CaSePb to SrSePb, and 16 μ from CaSeBi to SrSeBi in the sense of this rule.

E. B. MILLARD.

Fluorescence of uranyl salts under X-ray excitation. FRANCES G. WICK. Vassar. *Phys. Rev.* [2] 4, 418-25(1915).—The fluorescence excited in uranyl salts by X-rays differs from that excited by light in intensity only, and the intensity difference was explained by the greater absorption of these salts for light than for X-rays. The phosphorescence following excitation was of shorter duration and less intense for light than for X-rays, probably on account of the difference in penetration of the 2 kinds of radiation.

Gamma ray measurements with mesothorium preparations. STEFAN MEYER AND VIKTOR F. HESS. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, IIa Abt.* 123, 1443-58(1914).—Tables are given for calcg. the γ -ray equivalents of Ra-free Meso-Th preps. on a Ra-Ra C basis, using measurements of the penetration of the rays and the age of the specimen.

G. L. WENDT.

Soft secondary beta rays from gamma rays. K. W. F. KOHLRAUSCH AND ERWIN SCHRÖDINGER. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, IIa Abt.* 123, 1319-67(1914).—The incidence radiation from thin foils of Al, Cu, Zn and Pb grows with their thickness until the sp. range is reached, when it remains const. The emergence radiation, always slightly harder than the former, also grows with the thickness of thin foils but later decreases in accord with the absorption law of the primary γ -rays. Measurements of the radiation at various angles of incidence agree with calculations from the assumptions: that the secondary radiation is a vol. effect; that the radiation from a vol. unit is not distributed equally but is chiefly in the direction of the primary beam; and that both primary and secondary rays are absorbed under exponential laws. The persisting scattered radiation from very thin foils makes it improbable that the original direction of the secondary electron is always that of the primary beam. Three characteristic constants are distinguished: C , the radiation coeff., is const. for Al, Fe, Ni, Cu and Zn, but rises with Sn and is doubled for Pb; β , the asymmetry coeff., decreases with increasing at. wt.; μ , the absorption coeff., is independent of the nature of the radiator, but depends on the absorber and the hardness of the primary beam. The radiation coeff. for secondary γ -rays for Cu and Zn is about 1% of that for β -rays.

G. L. WENDT.

Theoretical investigations on the cause and magnitude of the variations in range among individual alpha rays of a homogeneous beam. LUDWIG FLAMM. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, IIa Abt.* 123, 1393-1426(1914).—Since homogeneous α -rays are emitted at equal velocities the variations in range are due to

events in the trajectory. Probability calculations on the basis of Rutherford's atomic model show that the occasional large-angle deflections of the α -particle by an encountered at. nucleus are too infrequent to account for the variations in range, as are also the energy losses on collisions with nuclei. Encounters with electrons cause large energy losses but the probability of individual variations is insufficient to account for the variation of 0.8 cm. in the range of Po, found by Geiger. Only the variations in the final 0.08 cm. of the range, traced by Friedmann, may be accounted for on this basis.

G. L. WENDT.

New determinations of the ranges of polonium, ionium and actinium. STEFAN MEYER, VIKTOR F. HESS AND FRITZ PANETH. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, IIa Abt.* 123, 1459-88(1914).—Very careful detns. of the ranges in air at 0° resulted as follows: Po, 3.64 cm.; Io, 2.95 cm.; Act, 3.38 cm.; Radio-Act, 4.0 cm. and 4.37 cm.; Act X, 4.04 cm.; Act C, 4.88 cm.; Act Em, 5.28 cm., and Act A, 5.94 cm. The new value of Po fits precisely into the graph of the Geiger-Nuttall rule, $\log \lambda = A + B \log R$, (C. A. 6, 26), and eliminates the only exception to that rule in the U-series. Using the above range, the rule gives Io a half-life period of 1.1×10^4 yrs., about one-tenth of the accepted value. This invalidates Russell and Rossi's proof of the spectroscopic identity of Th and Io, since their Th contained only 2% of Io instead of 10% (C. A. 7, 1135). The new values for the Act-series lie on a straight line which cuts the U-series line at U 2, indicating the genesis of Act from U 2. Radio-Act gives 2 sets of α -rays, and the same is suspected of Act, which may have an isotope or a parent with a range of 4.15 cm.

G. L. W.

Experiments on slow cathode rays. J. J. THOMSON. *Electrician* 75, 60(1915); cf. C. A. 9, 21, 1006.—It is pointed out that between the long elec. waves and the extreme infra-red light waves of Rubens, there is no gap, but a gap of about 7 octaves exists on the other side of the spectrum between the extreme ultraviolet Lyman rays of the Schumann region and the longest X-rays. By using a Coolidge tube of special design, having a movable target of Al on one side and Cu on the other, the rays could be passed either into an ionization chamber containing SO₂ or into a second bulb similarly made. This second bulb was silvered inside for the detn. of the total number of electrons given out by the second target. The curve showing the number of negative particles produced for each p. d. indicates that a minimum potential of 15 v. is required to give rise to any appreciable radiation. This indicates that the emission of characteristic Röntgen rays by an atom depends upon the ionization of the atom and each ionized atom gives one unit of radiation, the kind depending upon the position of the electrons in the atom, and the radiation is due to the return of the electrons to the atom. By the use of the double metal targets, it was shown that metals give spectrum lines in this newly explored range of soft radiation.

W. E. RUDER.

A determination of the diurnal variation of the radioactivity of the atmosphere at Manila by the active deposit method. O. W. BLACKWOOD. Univ. Philippines. *Philippine J. Sci.* (A) 10, 37-47(1915).—A large and fairly regular diurnal variation has been observed for the active deposit at Manila, the mean night-value being about 3 times that of the day. The mean active deposit seems to vary with the humidity, but in the individual curves there are wide divergences. There is no evident relation between the wind and the amt. of deposit collected. The active deposit collected on Mount Maquiling, elevation 1,140 m., is about twice that of Manila. The diurnal variation on the mountain is apparently the inverse of that of Manila, the night collection being smaller than the day. The half-period value found at Manila is about 62 min., which corresponds to less than 15% Th active deposit.

W. H. ROSS.

The radioactivity of the atmosphere. EDOUARD JACOT. *South African J. Sci.* 11, 271-4(1915).—The radioactivity of the atm. in the vicinity of South African Col.

was detd. by the method of collecting the active deposit on a bare Cu wire exposed horizontally a few meters above the ground and charged to a negative potential which was varied from -700 to $-12,000$ v. The time of exposure was varied between 4 and 18 hrs. The rate of decay of the collected deposit, which was independent of the potential and of the time of exposure, showed that products of both Ra and Th contributed to the initial activity of the wire, and that the fractions of the initial activity contributed to by the respective deposits were about const. In a typical case 80% of the initial activity was due to Ra deposit, and 20% to the Th. From the results thus obtained it was calc. that there is per unit vol. of the atm. at Cape Town about 28,000 times as much Ra Em as Th Em.

W. H. Ross.

The emission and absorption of gas residues in Röntgen tubes and the emission of X-rays. P. CARDANI. Univ. Parma. *Atti accad. Lincei* 24, I, 105-19(1915).—It is known that Röntgen tubes ought to undergo a long process of exhaustion in order to eliminate the gas occluded in the electrodes and glass walls in order to obtain the best conditions for the emission of X-rays. This gas is not freely released even with prolonged rarefaction so that in order to obtain exhaustion it is necessary to enclose the tube in a special case, *e. g.*, asbestos, and raise the temp. by passing a sufficiently intense current, since the electrical discharge facilitates the emission of occluded gases. In order to avoid blackening the tubes by pulverization of the anticathodic Pt the manufacturers add a 3rd electrode that serves as an anode during the exhaustion. Skinner (*Physik. Z.* 6, 610(1905)) found that the gas evolved from cathodes of different metals is H, and that its emission is accompanied by an absorption at the anode, and that the emission is observed again after the electrodes have been left in repose some time owing to the removal of gas from the interior to the surface. Hirsch and Soddy (*Phil. Mag.* 14, 779(1907)) observed that in X-ray tubes with Al electrodes gas is emitted, the formation of which depends on a trace of Na in the electrode, but the nature of which was not detd. The fact that Röntgen tubes on long-continued use tend to harden shows that the electrodes reabsorb the gas contained in them. The purpose of the present paper was to elucidate some of the complex questions connected with the above mentioned and other phenomena and to learn the conditions necessary for the best results. The methods, app., and results are given in detail. The conclusions are as follows: The Al electrodes of Röntgen tubes after having been in contact with the air contain in considerable amts. occluded gas that is not released spontaneously at ordinary temps. nor on more prolonged exhaustion, but which is emitted through the passage of the discharge. The emission of the gas takes place spontaneously at high temp. but also in this case is considerably facilitated by the passage of the discharge: the quantity of gas liberated is much larger the higher the temp. The occluded gas encounters great difficulty in reaching the surface of the electrode even at high temps. and with prolonged exhaustion. Owing to this difficulty the electrodes may be exhausted superficially so that the pressure remains constant with the passage of the discharge even for some days, *i. e.*, the occluded gas in the deeper layers does not diminish the exhaustion produced by coming to the surface; this condition remains until the discharge is set up again and the emission of gas again begins. Having obtained the superficial exhaustion, the electrodes reabsorb, under the action of the discharge and at ordinary temp., the gas which was emitted at a high temp. under the action of the discharge. The emission and absorption depend on the particular conditions of the exhaustion in which one finds the superficial layers of the electrodes. Additional series of expts. showed among other things that the law governing the emission and absorption of gas by the electrodes is exponential (formula given). When a suitable but variable amt. of air was placed in Röntgen tubes it was found to behave quite differently from the gas ordinarily evolved so that it is concluded that chemically

the gas emitted is quite different from air. The nature of the gas was not stated in this paper.

COLIN G. FINK.

The electric furnace in the foundry. W. G. KRAUZ. *Bull. Am. Inst. Min. Eng.* 1915, 927-30.—The experience of the Nat. Malleable Castings Co. with elec. furnaces is given. A 6-ton Héroult furnace, 3-phase, 60-cycle, equipped with Thury regulators was installed in 1912 and has been in continuous operation since that time. Over 20,000 tons of both C and alloy steels have been made. A power factor of 94 is obtained. There is good regulation and uniform load on the line even when cold melting. The power consumption is 150 kw. hrs. per ton in the case of hot metal charges, and 500-600 kw. hrs. per ton in the case of cold charges. The greatest advantage is in the abs. control and uniformity of product. The other advantages, absence of segregation, almost entire elimination of S, great tenacity, high ratio of elas. limit to ultimate strength of product, and perfect control of the pouring temp. are discussed.

W. E. RUDER.

Increasing aluminium consumption in U. S. ANON. *Elec. Rev. West. Elec.* 67, 68(1915).—In 1914, 79,129,000 lbs. of Al were consumed in U. S. as compared with 72,379,000 lbs. in 1913 and 65,607,000 in 1912. Details are given.

Aluminium rectifier. G. SCHULZE. *Archiv. f. Elek.* 3, No. 1(1914); *Elec. World* 65, 1552(1915).—The efficiency of electrolytic rectifiers with aq. solns. is limited by 3 kinds of losses, *vis.*: ohmic resistance, imperfection in the impermeability in reverse direction, and the necessity of attaining a certain minimum voltage before the current will pass in the allowed direction. This last loss is a function of the formation voltage of the Al plates. These losses are calcd. for two arrangements of the rectifier—the transformer system (Fig. 1) and the Graetz system (Fig. 2). The a. c. is applied at E and the d. c. taken off at e. The min. voltage for different electrolytes is first calcd. In both systems the possible efficiency reaches 80-85%, but this max. value is reached for a unidirectional e. m. f. of 60-80 v. for the transformer system and 100-150 v. for the Graetz system.

For small voltages these efficiencies are low. For 5 v. the max. possible efficiency for the transformer system is 40% and for the Graetz system 25%.

W. E. RUDER.

Electrolytic production of oxygen and hydrogen. A typical plant. ANON. *Elec. Rev. West. Elec.* 66, 1170(1915).—A description is given of the Bettendorf Iowa Plant. Fifty generating cells connected in series across a 110 v. d. c. line, each cell requiring 400 amp. at 2.2 v. and producing about 3.5 cu. ft. of O and 7 cu. ft. H per kw. hr. The output per 24 hr. day is 4000 cu. ft. O and 8000 cu. ft. H. The O is 99.5% and the H 99.9% pure. The gases are stored in large tanks and for shipment they are compressed at 1800 lbs. into 100 or 200 cu. ft. steel cylinders. The current for the cells is obtained by means of a motor generator set: 440 v., 3-phase, 60 cycle induction

motor connected to a 50-kw. shunt wound, commutating-pole generator. A 20 h. p. boiler furnishes distd. H_2O for the cells. Z. SMLOVICI.

Mercury arc rectifier for charging small batteries. *Elec. World* 66, 102(1915); *Elec. Rev. West. Elec.* 67, 84(1915), 2 illus. C. G. F.

Methods and means for interrupting electric currents and avoiding arcing at the contacts. W. BURSTYN. *Naturwissensch.* 3, 301(1915).—B. has made a careful study of various types of interrupters and has invented an improved form (Ger. pats. 260,903, 268,889, 269,254). With the ordinary simple interrupter, using Pt contacts, no disturbing arcing takes place until the voltage is increased to about 320. At 320 even 0.001 amp. is sufficient to give a large arc; this arc does not give the spectrum of the contact metals, but that of N. With increased voltage the violet tinted N arc changes to a bright yellow metal (Pt) arc. B.'s interrupter is fitted with Ag electrodes and no arcing takes place even at 500 v. and 150 amp. (a. c.), providing the interruption is gradual. D. c. of 15 amp. and 220 v. can be successfully interrupted, providing a condenser of 0.3 microfarad is connected in circuit. Three diagrams of connections are shown. C. G. F.

Battery-bell signalling system. R. V. WHEELER. *Electrician* 75, 132-4(1915).—A report on the safety of battery-bell systems in coal mines. It is shown that the most sensitive mixts. contain between 7.5 and 9% CH_4 . Such mixts. require only about 0.2 amp. for ignition. On either side of these figures the current required rises very rapidly. The self-induction of the circuit has a decided effect. The ignition current of any mixt. rises rapidly as soon as the self-induction of the circuit falls below about 0.03 Henry. Results of the same order were obtained with currents of 60, 30 and 15 v. All bells examd. were capable of giving a highly dangerous break-flash when used on 10 wet Leclanché cells at 15 v. Ten dry cells gave a still more dangerous flash owing to lower internal resistance. Most bells are "over-powered." One bobbin with a smaller number of turns gave results just as good with less self-induction. In order to make the system safe in the most sensitive mixt. the following recommendations are made: Use a battery of 10 wet Leclanché cells (quart size) and introduce a non-inductively wound resistance coil in series with the magnet coil, or increase the resistance of the magnet windings (as by using brass wire), or use a parallel winding, or introduce tin-foil strips between the layers of the coil to produce eddy currents which absorb the energy of the self-induction. The danger of ignition from the maintained spark at the trembler of the bell should be eliminated by using a flame-tight casing. Methods of conducting the above expts. are described. W. E. RUDER.

Electrometric titration (ZIEGEL) 7.

U. S., 1,143,181, June 15. M. A. FOOS. Dry-cell electric battery (structural features).

U. S., 1,143,586, June 15. W. LAIB. Potassium chlorate is made by electrolysis of a soln. of KCl containing a small amt. of K_2CrO_4 or $K_2Cr_2O_7$ at a temp. below 35°, using a graphite anode, followed by further electrolysis in another cell with a Pt anode

at a temp. above 70° which is maintained by the current flowing through the cell. The partial conversion in the cell with graphite anode reduces the cost of apparatus for any given desired yield.

U. S., 1,143,828, June 22. P. C. C. ISHERWOOD. **Dense anodes of manganese dioxide for electrolysis of copper, zinc or nickel from solution** are made from Mn ore by leaching it with HNO_3 or H_2SO_4 to remove Fe, Ni and Co from the ore, forming a pasty mixt. of the leached ore with a soln. of $\text{Mn}(\text{NO}_3)_2$, molding, drying and heating sufficiently to decompose the nitrate and repeatedly soaking in $\text{Mn}(\text{NO}_3)_2$ soln. and drying and heating until the pores of the material are compactly filled.

H. I. SCHLESINGER.

Studies on hydrates. A. JOHNSEN. Kiel. *Centr. Min. Geol.* 1915, 289-92.—As there appears to be some contradiction in the literature as to the behavior of the H_2O in $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, clear crystals of this salt were powdered and placed in a desiccator over CaCl_2 at ordinary temps. controlled within 1° . H_2O gradually escaped, until in 10-30 days, depending on actual temps., approx. 1 mol. H_2O was lost. The resulting hexahydrate does not inoculate satd. solns. of the salt, for although it is dextrorotatory, the crystals forming after its addition to a satd. soln. of MgSO_4 (containing 5% borax to produce faces showing the right- or left-handed character) are equally left and right. The fact that 1 mol. of H_2O differs from the others indicates that the true formula of the salt is $[\text{Mg}(\text{H}_2\text{O})_6]\text{SO}_4 \cdot \text{H}_2\text{O}$, the $(\text{H}_2\text{O})_6$ being probably more or less polymerized.

E. T. WHERRY.

Nature of residual valence. VIII. Stability of ammoniated chlorates, bromates and iodates. Thermal dissociation and explosion. FRITZ EPHRAIM AND ADOLPH JAHNSSEN. Bern. *Ber.* 48, 41-56(1915); cf. C. A. 8, 597.—Most of the following compds. were prepd. by passing NH_3 into a concd. aq. soln. of the metal salt, though in some cases it was necessary to add EtOH satd. with NH_3 ; some ammoniates were prepd. by heating in NH_3 at the requisite temp. **Copper tetraammine chlorate**, $\text{Cu}(\text{ClO}_3)_2 \cdot 4\text{NH}_3$, deep blue needles, d. 1.81; dissociation pressure at 97° is 36 mm.; at 116° , 55 mm.; 158° (approx.), 715 mm. **Copper hexaammine chlorate**, $\text{Cu}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$, ultramarine blue, dissoc. pressure at -15° , 201 mm.; -1° , 286 mm.; 10° , 380; 20° , 491; 31° , 628 mm.; the shape of the curve indicates solid soln. **Nickel hexaammine chlorate**, $\text{Ni}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$, blue needles, m. 180° , d., 1.52; dissoc. pressure at 120° , 50 mm.; 140.5° , 75 mm.; 15° , 140 mm. **Zinc tetraammine chlorate**, $\text{Zn}(\text{ClO}_3)_2 \cdot 4\text{NH}_3$, colorless crystals, d. 1.84; dissoc. pressure at 114° , 16 mm.; 140° , 32 mm.; 165° , 50 mm.; 177° , 88 mm. **Zinc hexaammine chlorate**, dissoc. p. at -15° , 225 mm.; -14° , 232; -10° , 270; -8° , 304; -6° , 332; -2° , 388; 0° , 427; 1° , 449; 3° , 486; 6° , 550; 7.5° , 594; 10° , 690; 11° , 747 mm. **Cadmium hexaammine chlorate**, colorless crystals, d., 1.78; dissoc. p. at 69° , 89 mm.; 82° , 156; 94° , 241; 103.5° , 330; 116.5° , 530; 122° , 772 mm. **Cadmium tetraammine chlorate**; dissoc. p. at 116.5° , 117 mm.; 125.5° , 174; 136° , 335 mm. Co and Mn compds. were prepd. but they were too easily decompd. for detn. of a pressure curve. **Copper diaquo-tetraammine iodate**, $\text{Cu}(\text{IO}_3)_2 \cdot 2\text{H}_2\text{O} \cdot 4\text{NH}_3$, deep blue prisms, was prepd. by passing NH_3 into a soln. of CuNO_3 in concd. NH_4OH soln. **Copper pentammine iodate** was prepd. from the above by dehydrating at 160° in a current of NH_3 , and satg. with NH_3 in the cold; d., 2.72; dissoc. p. at 50.5° , 141 mm.; 65° , 260; 75° , 440; 82° , 640; 84.5° , 719 mm. **Nickel triaquo-pentammine iodate**, $\text{Ni}(\text{IO}_3)_2 \cdot 3\text{H}_2\text{O} \cdot 5\text{NH}_3$, forms reddish violet columns, and from it was obtained **nickel pentammine iodate**, light violet crystals, d. 2.97; dissoc. p. at 53° , 179 mm.; 65° , 365 mm.; 77° , 670; 79° , 905 mm. **Zinc tetraammine iodate**, white needles, d. 2.82; dissoc. p. at 77° , 44 mm.; 91.5° , 81; 106.5° , 141; 119° , 242; 130° , 356 mm. $\text{Cd}(\text{IO}_3)_2 \cdot 4\text{NH}_3$, d. 3.23; dissoc. p. at 91° , 381 mm.; 101° , 486; 110° , 709 mm. The temp. at which the dissociation pressure reaches 1 atm. was estd. by extrapolation by means of the Ramsay-Young rule, and the expression $^3\sqrt{v} = ^3\sqrt{T_{760}}$ (v = atomic vol. of the central atom) gave values for $\text{Ni}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$, $\text{Cu}(\text{ClO}_3)_2 \cdot 3\text{NH}_3$, $\text{Zn}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$ and $\text{Cd}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$ of 14.61, 13.02, 13.73 and 17.22, resp.; the discrepancy in the case of Cd is ascribed to a large change in the at. vol. of Cd. on formation of the ammoniate. Many of the above compds. can be exploded by concussion, or by heating. On heating in an open tube explosion is believed to take place usually at the temp. at which the dissociation pressure reaches 1 atm.; the authors state that this is due to the fact that "below the dis-

sociation temp., the splitting off of the NH_3 mol. is an endothermic process. However, when the dissociation temp. is exceeded, the splitting off of NH_3 gives off heat." When heated in closed tubes explosion took place at a higher temp. than in an open tube with the chlorate compds. Following are the explosion temps. (mean) of various compds. in open and closed tubes, resp.: $\text{Cu}(\text{ClO}_3)_2 \cdot 4\text{NH}_3$, 158° , 208° ; $\text{Ni}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$, 201° , 240° ; $\text{Zn}(\text{ClO}_3)_2 \cdot 4\text{NH}_3$, 205° , 289° ; $\text{Cd}(\text{ClO}_3)_2 \cdot 6\text{NH}_3$, 184° , 300° ; $\text{Cu}(\text{BrO}_3)_2 \cdot 4\text{NH}_3$, 140° , 149° ; $\text{Ni}(\text{BrO}_3)_2 \cdot 6\text{NH}_3$, 195° , 191° ; $\text{Zn}(\text{BrO}_3)_2 \cdot 4\text{NH}_3$, 169° , 159° ; $\text{Cd}(\text{BrO}_3)_2 \cdot 6\text{NH}_3$, 192° , 193° . The iodate compds. did not explode in an open tube, but in a closed tube all 4 exploded between 210 and 219° . Cf. following abstr.

GEORGE W. MOREY:

Nature of residual valence. IX. Influence of the position of the neutral part in the molecule on its stability. F. EPHRAIM. Univ. Berne. *Ber.* 48, 624-9(1915); cf. preceding abstr.—A theoretical discussion in which examples are cited tending to show that for a given anionic complex, change of the cation increases the stability when such change would decrease the stability of complex cations. The reversal of the ability of neutral salts to "salt out" amino acids upon addition of a trace of acid or alkali is discussed upon the assumption that complex compds. are formed: alk.

relations. **X. Limits of the stability of complex anions.** F. EPHRAIM AND E. HOCH-ULLI. *Ibid* 629-37.—Various halide salts of organic bases were tested for their temp. stabilities. Bromides were found to be on the whole somewhat less stable than chlorides, and iodides decidedly less stable than either. Measurements of the pressure at various temps. are given for the chlorides of 14 bases, for the bromides of 3 bases, and iodides of 3 bases; of the last, one only is considered entirely reliable. **XI. Zinc amines.** F. EPHRAIM AND E. BOLLE. *Ibid* 638-48.—Measurements of the dissociation pressure at various temps. were made for a large number of zinc-ammine salts. By comparison of these data with those for Ni-ammine salts, exptl. evidence is obtained for the principle that in compds. of the type $[\text{M}^{\text{II}}(\text{NH}_3)_x] \text{X}_3$, the stability of the neutral part depends upon at least 2 superimposed factors, the cationic metal and the anion. According as the one or the other preponderates, the resultant may differ so greatly that parallel series of analogously composed compds. may present entirely different stability relations. In the Ni series the stabilities found were $\text{ClO}_4 > \text{I} > \text{Br} > \text{ClO}_3 > \text{NO}_3 > \text{S}_2\text{O}_8 > \text{Cl} > \text{SO}_4 > \text{S}_2\text{O}_7 > \text{S}_2\text{O}_8 > \text{NO}_2 > \text{H}_2\text{PO}_4 > \text{HCO}_2 > \text{CNS} > \text{CH}_3\text{CO}_2$; while for the Zn series the order was found to be $\text{S}_2\text{O}_8 > \text{I} > \text{Br} > \text{Cl} > \text{S}_2\text{O}_7 > \text{S}_2\text{O}_8 > \text{HCO}_2 > \text{ClO}_4 > \text{SO}_4 > \text{NO}_3 > \text{C}_2\text{O}_4 > \text{ClO}_3 > \text{CNS} > \text{C}_7\text{H}_5\text{O}_2 > \text{CH}_3\text{CO}_2$ and NO_2 . The stability limits at atm. pressure are scattered over more than 200° in the Ni compds., while those of the Zn series lie within 70° , showing that in the case of Ni change of the anion produces a much greater effect than with Zn. The abs. temp. of decompn. (NH_3 pressure = 1 atm.) is tabulated for 22 Zn-ammine salts and their heats of formation calcd. with the Nernst formula. Observations of the decompn. temps. of some Cu-ammine salts are appended.

A. R. M.

Salts of complex metallopyrophosphoric acids. A. ROSENHEIM AND T. TRIATA-PHYLLIDES. Berlin. *Ber.* 48, 582-93(1915).—Indications of a tendency of the trivalent metals to enter a complex anion with $\text{H}_2\text{P}_2\text{O}_7$ in which the ordinary reactions of the metal ion are suppressed, are scattered through the literature. In a systematic investigation of this tendency the authors have prepd. several new compds. When a soln. of Mn_2O_3 in ice-cold concd. HCl is allowed to drop into cold satd. soln. of $\text{Na}_4\text{P}_2\text{O}_7$, a violet flocculent ppt. is formed by each drop; this dissolves to form a deep violet soln.; from the satd. soln. microcryst. octahedrons of pale red color, insol. in cold,

decompd. by boiling water, separate. The formula, $\text{Na}[\text{MnP}_2\text{O}_7] \cdot 5\text{H}_2\text{O}$ was found in agreement with Christensen (*J. prakt. Chem.* [2] 28, 24 (1883)). The *potassium* and *ammonium* salts were similarly prepd.; the former in 2 forms with $5\text{H}_2\text{O}$ and $3\text{H}_2\text{O}$, the latter with $3\text{H}_2\text{O}$. By double decompn. from the NH_4 salt the *silver* ($3\text{H}_2\text{O}$) and *barium* ($5\text{H}_2\text{O}$) salts were prepd. Similarly with CrCl_3 were prepd. $\text{Na}[\text{CrP}_2\text{O}_7] \cdot 8\text{H}_2\text{O}$, gray-blue, and with $5\text{H}_2\text{O}$, green, and the *potassium* ($5\text{H}_2\text{O}$, green), and *ammonium* ($6\text{H}_2\text{O}$, gray-blue) salts. Properties are like those of the Mn salts except that the Cr salts are more readily hydrolyzed so that the Ag and Ba salts could not be prepd. From Al salts no cryst. complex salts could be obtained. Freshly pptd. $\text{Fe}_4(\text{P}_2\text{O}_7)_3$ dissolves in $\text{Na}_4\text{P}_2\text{O}_7$ soln. and a reddish grey cryst. dust seps. on standing (addition of NaCl increases the yield) or on evap. *in vacuo* over H_2SO_4 . It is quickly decompd. by water. Analysis of 3 preps. gave poorly concordant results approximating $\text{Na}_2\text{Fe}_4(\text{P}_2\text{O}_7)_3 \cdot 28\text{H}_2\text{O}$ instead of Pascal's (*C. A.* 3, 1505) $\text{Na}_4\text{Fe}_2(\text{P}_2\text{O}_7)_3 \cdot 9\text{H}_2\text{O}$. $\text{Bi}_4(\text{P}_2\text{O}_7)_3$ dissolves in a soln. of $\text{Na}_4\text{P}_2\text{O}_7$ and after standing a short time microscopic prisms of $\text{NaBiP}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ sep. It also dissolves in sols. of $\text{K}_4\text{P}_2\text{O}_7$ and $(\text{NH}_4)_4\text{P}_2\text{O}_7$ but no cryst. products sep. TiCl_3 dissolves in sols. of alkali pyrophosphates and from the concd. soln. of the Na salt a cryst. ppt. of white needles slightly contaminated by Ti_2O_3 is obtained, decompd. by water; analyses of 3 preps. approximated $\text{Na}_4\text{TiP}_2\text{O}_7 \cdot 6\text{H}_2\text{O}$. No cryst. ppt. formed from the K and NH_4 salt sols. K_2MoCl_6 gave stable $\text{NaMoP}_2\text{O}_7 \cdot 12\text{H}_2\text{O}$, brown-yellow, microcryst., but trivalent U and Ti salts caused evolution of H and oxidation of the metal. When crystals of V alum were thrown into $\text{Na}_4\text{P}_2\text{O}_7$ soln. there was formed a flocculent green ppt. which dissolved in excess to a permanent green soln.; this solidified to a glassy mass *in vacuo* over H_2SO_4 . The flocculent ppt. formed by adding alkali pyrophosphate to excess V alum gave upon analysis $\text{V}_4(\text{P}_2\text{O}_7)_3 \cdot 30\text{H}_2\text{O}$. Ce salts behaved like those of V. Amorphous $\text{Ce}_4(\text{P}_2\text{O}_7)_3 \cdot 12\text{H}_2\text{O}$ was prepd. $\text{Co}_2(\text{SO}_4)_3$ thrown into excess of alkali pyrophosphate gave entirely stable dark green sols. from which no cryst product could be obtained. Upon attempts to isolate the amorphous ppt. as with V, the ppt. decompd. with evolution of O even in the soln. and upon drying cobalto-pyrophosphate was found.

A. R. MIDDLETON.

Equilibrium in the system disodium hydrogen arsenate, lead nitrate and water. B. E. CURRY AND T. O. SMITH. *J. Am. Chem. Soc.* 37, 1685-8 (1915).—Sols. of Na_2HASO_4 and of $\text{Pb}(\text{NO}_3)_2$ were added to H_2O in various quantities such that the sum of As_2O_5 + PbO was 2.0 g., to 448 g. H_2O , and the bottles containing the mixts. were rotated at 25° and kept in the thermostat for 3 months. From analyses of the supernatant liquid and the solid phase it was shown that the only compd. in the system was PbHASO_4 .

E. B. MILLARD.

Chlorine salts of ruthenium. A. GUTBIER AND F. KRAUSS. Stuttgart. *J. prakt. Chem.* 91, 103-15 (1915).—The following pentachloro salts were prepd. by mixing sols. of the components, the concn. of the sols. in each case being adjusted when possible so that pptn. was immediate. The compds. are all glittering, well formed crystals, hydrolyzed by H_2O , but slightly sol. in H_2O ; they can be recrystd. from dil. HCl soln. *Methylammonium pentachlororuthenate*, $(\text{MeNH}_2)_2\text{RuCl}_5$, reddish black crystals; *dimethylammonium*, $(\text{Me}_2\text{NH})_2\text{RuCl}_5$, small black crystals with reddish tint; *trimethylammonium*, black crystals; *tetramethylammonium*, black crystals; *ethylammonium*, black crystals; *diethylammonium*, black crystals; *triethylammonium*, black crystals; *tetraethylammonium*, black crystals; *n-propylammonium*, black needles; *i-propylammonium*, black needles; *dipropylammonium*, red crystals; *tripropylammonium*, black needles; *n-butylammonium*, black crystals; *i-butylammonium*, reddish brown crystals; *di-i-butylammonium*, dark red crystals; *tri-i-butylammonium*, black crystals; *guanidinium*, dark red crystals; *ethylenediammonium*, brick red crystals; *pyridinium*, golden yellow crystals; β -*picolinium*, black

crystals; *piperidinium*, black needles; *quinolinium*, dark red crystals. The following hexachlororuthenates were prepd. by mixing solns. of RuCl_3 and the chloride of the base, dissolving the ppt. in HCl , and satg. with Cl in the cold (cf. *C. A.* 1, 1227). *Tetramethylammonium hexachlororuthenate*, $(\text{Me}_4\text{N})_2\text{RuCl}_6$, black crystals; *tetraethylammonium*, black crystals; *tripropylammonium*, black crystals; *di-*i*-butylammonium*, black crystals; *tri-*i*-butylammonium*, black crystals; *di-*n*-amylammonium*, red crystals; *guanidinium*, black crystals; β -*picolinium*, black crystals; *piperidinium*, black crystals; *quinolinium*, black crystals.

GEORGE W. MOREY.

Manganese sulfides. V. M. FISHER. *J. Russ. Phys. Chem. Soc.* 46, 1481-519 (1914).—Owing to the contradictory data found in the literature regarding the different modifications of MnS , an exam. was made of the conditions of prepn. and the properties of each of them. The results of the extensive work may be summarized as follows: Green MnS is formed only when $(\text{NH}_4)_2\text{S}$ or NH_4HS is used as precipitant, and even then only when the NH_4Cl in presence of which the pptn. takes place does not exceed a certain concn., the limit of this concn. differing with the amt. of free NH_3 in the soln. To produce it without an excess of NH_3 , the soln. must be hot, the addition of MnCl_2 to the precipitant very slow, and the liquid must be constantly and vigorously stirred, but with an excess of NH_3 green MnS is produced even at ordinary temp. Usually the green MnS is microcryst., but by adding the MnCl_2 in small portions at a time the crystals may be made to grow till they become visible to the naked eye. Green MnS may be obtained either anhydrous or hydrated, the amt. of H_2O in the salt varying from 0 to 17%, according to the concn. of NH_3 and the length of time the MnS is left in contact with the mother liquor. When the above conditions are not adhered to, or under all conditions when alk. sulfides are used as precipitants the rose-colored MnS results. When obtained by using $(\text{NH}_4)_2\text{S}$ the compn. of the latter is $\text{MnS} \cdot x\text{H}_2\text{O}$, x varying from 22.9 to 55.9%, while NH_4HS ppts. a sulfide containing a little more S , and Na_2S a sulfide containing a little less S than corresponds to $\text{MnS} \cdot x\text{H}_2\text{O}$. In the last case the ppt. possibly contains some $\text{Mn}(\text{SH})_2$, while in the 2nd it is contaminated with $\text{Mn}(\text{OH})_2$. By special precautions rose-colored $\text{MnS} \cdot \text{H}_2\text{O}$ may be prepd. No matter how made and what its compn., rose-colored MnS is always amorphous. The rose-colored MnS obtained by means of NH_4HS changes to the green modification when treated with NH_3 and $(\text{NH}_4)_2\text{S}$, while the 1 pptd. by Na_2S undergoes this change when repeatedly washed with H_2O . The transformation of the rose-colored into the green MnS may be prevented by the addition of $\text{NH}_2\text{OH} \cdot \text{HCl}$. Pptd. by H_2S in acid soln. MnS has a red or orange-red color, and according to the concn. of acid is either anhydrous or contains 1 mol. H_2O . By triturating the other modifications of MnS in the dry condition they change to the green variety. Indications were obtained of the existence of $\text{MnS} \cdot 3\text{Mn}(\text{OH})_2$. Very minute descriptions are given for prep. each of the above modifications.

H. M. GORDIN.

Hydrazine. W. SCHLENK AND TH. WEICHSSELFELDER. *Univ. Jena. Ber.* 48, 669-76 (1915); (Cf. Stollé, *C. A.* 5, 1879).— N_2H_4 prepd. according to Raschig (*C. A.* 4, 2615) was treated with Na in an atm. of N , absolutely dry and free from O and CO_2 . H and much NH_3 were evolved and a colorless cryst. ppt. was formed. Excess N_2H_4 was distd. off *in vacuo*. The dry residue was pure white and violently exploded when removed from the N -filled vessel or on contact with moisture. Widely varying results were obtained in detns. of the atomic proportions $\text{Na}:\text{N}$ in the decompn. products. It was concluded that the N_2H_4 was not absolutely free from hydrate. N_2H_4 by Raschig's process was then treated with a little Na in an atm. of N and distd. *in vacuo*, using a specially devised app. (pictured). The product was entirely free from hydrate. Upon treating it with Na the metal was at first coated with a dark blue layer (Na -hydrazonium?). Upon

shaking the liquid became yellow. Much NH_3 was formed and very little H, showing that the nascent H was used nearly completely for reduction of N_2H_4 . After removal of excess N_2H_4 , the residue consisted of brilliant cryst. leaflets, which upon analysis proved to be $\text{NH}_3\cdot\text{NHNa}$. It is extremely reactive, exploding violently at the least breath of air or trace of moisture or alc. It could be decompd. without explosion by covering with much dry C_6H_6 and then gradually shaking into it C_6H_6 containing a little alc. When sufficient is added the solid disappears and the resulting soln. of N_2H_4 and EtONa seps. from the C_6H_6 . Water may then be added safely. Analysis of 2 preps. gave 2 atoms N:1.039 and 1.019 atom Na, resp. *A case of isomerism in two simple derivatives of hydrazine.* Upon mixing N_2H_4 and MeOH much heat is evolved, presumably by the formation of an alcoholate. This is much less stable than the hydrate for upon distn. the b. p. constantly rises. That at lower temp. a true chem. individual was present is shown by putting mol. amts. of N_2H_4 and MeOH in a sealed tube and cooling with solid CO_2 . The liquid solidifies completely to homogeneous colorless needles, which melt at once on bringing to room temp. This hydrazine

alcoholate is isomeric with the hydrate of Me-hydrazine:

$$\begin{array}{c} \text{H} & & \text{H} \\ & \diagdown & / \\ & \text{N} - \text{N} < \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array} \begin{array}{c} \text{H} \\ | \\ \text{CH}_3 \\ | \\ \text{OH} \end{array} \quad \text{and}$$

E. G. R. ARDAGH.

Electrometric titration. H. ZIEGL. *Trans. Am. Electrochem. Soc.* 26, 91-7 (1914); cf. *C. A.* 9, 898.—To det. the end point of a titration, the author makes use of the change of potential (about 0.2) to operate a relay to close the buret. The app. used was similar to that of Forbes and Bartlett (cf. *C. A.* 7, 3938) except that a Weston No. 30 relay was used instead of a galvanometer. When the change took place, contact was made in a circuit having in it a telegraph sounder with a narrow arm 17.8 cm. long. This was attached to one side of the buret stopcock tip with a piece of fine chain. Rapid stirring was obtained by means of a small battery motor, driving a deeply nickeled disk of sheet Pt which formed the O electrode. Data given indicate very good checks obtained by this method. It was pointed out in discussion that the method is particularly adapted to the detn. of small amts. of Cl in H_2O . It was further suggested that the change in resistance in acid and alkali titration could be utilized in a similar device.

W. E. RUDER.

Inner paraffin coating for volumetric apparatus. G. POVARNIN. *J. Russ. Phys. Chem. Soc.* 46, 1898-905 (1914).—In order to avoid the adherence of droplets of liquid to the inner surface of volumetric vessels, P. advises coating them with a layer of pure

paraffin. Evidently solns. of I or alkali in alc. cannot be used with such app. Among the advantages of such vessels are the absence of interaction between aq. alkali and the glass and the possibility of drawing fractions of drops from burets. H. M. GORDIN.

Note on standardization of permanganate. H. E. MOYER. *Chem. Analyst* 13, 7-9(1915).—Weigh out KMnO_4 necessary to make the soln. somewhat weaker than the desired concn. in order to allow for some decrease in vol. by evapn., and keep near the b. p. on the steam plate for 2 days. Prepare in a similar manner a smaller amt. of a stronger soln. Remove pptd. MnO_2 by filtration through asbestos over broken glass in a funnel. Det. the concn. of the 2 solns. and the amt. of the stronger to be added to the weaker in order to bring it to the desired strength. H. M. LANCASTER.

Specific absorption of reagents for gas analysis. R. P. ANDERSON. Cornell Univ. *J. Ind. Eng. Chem.* 7, 587(1915).—Introductory note. A. defines the specific absorption as the vol. of a gas which a certain reagent will absorb up to the point at which the gas is not completely removed from its mixt. with other gases, expressed in cc. of gas per cc. of reagent. ISADOR MILLER.

Reagents for use in gas analysis. I. Alkaline pyrogallol. R. P. ANDERSON. Cornell Univ. *J. Ind. Eng. Chem.* 7, 587-96(1915).—Results on the specific absorption of alk. pyrogallol (see preceding abstr). The best soln. is prepd. by dissolving 15 g. pyrogallol in 100 cc. KOH soln., sp. gr. 1.35. Detailed instructions as to the method of analysis, apparatus, etc., are included. ISADOR MILLER.

Separation of manganese as sulfide from the alkali and the alkaline-earth metals. V. M. FISHER. *J. Russ. Phys. Chem. Soc.* 46, 1519-26(1914).—After pointing out the inconvenient features of detg. Mn as MnS in presence of alk. and alk.-earth metals and making use of his previous expts. (cf. C. A. 9, 2197), F. proposes 2 rapid and exact methods: (1) *As green MnS.* To 100-200 cc. of the analytical soln. add 5-15 g. of NH_4Cl and 50-60 cc. of NH_4OH ($d_{40} 0.895$). From a dropping funnel whose delivery point has been drawn out to a diam. of $\frac{3}{4}$ mm. add slowly during 10-15 min. 50-100 cc. of freshly prepd. NH_4HS (from 2.5% NH_4OH), constantly and vigorously stirring the liquid. If the rose-colored MnS produced at first has not by this time completely changed to the green variety, stopper the vessel and set it aside for 0.25-1.5 hrs. When all of the ppt. has turned green, dil. the liquid to 500-700 cc., collect the ppt. on a filter and wash it with H_2O containing some NH_4Cl and NH_4HS . The Mn is then detd. either as MnS by calcining the ppt. mixed with S in a current of H, or as phosphate by dissolving it in dil. HCl and adding a sol. phosphate. The presence of AcONH_4 does not interfere in the method. (2) *As rose-colored MnS.* The rose-colored MnS obtained in the 1st part of the above method usually is so dense that it is readily sepd. by filtration. Hence it is not necessary to wait till it has changed to the green variety, except when the supernatant liquid is turbid, which happens when the pptn. is too fast. Completely to prevent the formation of green MnS , 0.5-1 g. of $\text{NH}_4\text{OH.HCl}$ is added to the soln. before pptn. The detn. is finished in the same manner as above. Numerous detns. proved the exactness of these methods. H. M. GORDIN.

Micro-electroanalysis. E. H. RIESENFELD AND H. F. MÖLLER. *Z. Elektrochem.* 21, 137-43(1915); cf. Heinze, C. A. 8, 2322.—Based on exptl. data reported in detail, the authors have worked out methods for the micro-electroanalytical detn. of Cu, Ag, and Hg. A content of 5 mg. per l. can be detd. with an error of about 0.5%. This relatively large error is due to the inability to obtain electrodes of const. wt. (the wt. of the Pt electrodes used varied within above limits, owing to variation in the gas charge (Gasbeladung); perhaps also to oxide and hydride formation). Other sources of error, such as impurities in the electrolyte addition, incompleteness of pptn., spongy deposits, and change in deposit after electrolysis, were obviated. The following conditions are recommended:

	Cu.	Ag.	Hg.
Electrolyte addition.....	10 cc. 2NHNO ₃	2 cc. 2NHNO ₃ & 1 cc. alc.	2 cc. 2NHNO ₃
Temp.....	90°	50-60°	0°
Current.....	2 v., 10 milli-amp.	1.35 v., 4 milli-amp.	3 v., 10 milli-amp.
Minimum time.....	2 hrs.	6 hrs.	6 hrs.

F. W. SMITHER.

New method for volumetric determination of nickel. GINO ZUCCARI. Padova. *Ann. chim. applicata* 3, 277-9(1915); cf. Zuccari, *C. A.* 9, 771.—Dissolve 74.482 or 50.771 g. Na nitroprusside in a l. H₂O. The 1st soln. will ppt. 0.01467 g. and the 2nd 0.01 g. Ni per cc. The titrating soln. is added from a buret to the Ni soln. which is constantly stirred with a glass rod till the ppt. assumes an ashy color in the decolorized liquid, a drop of which is filtered and tested with Na₂S. A black color indicates excess of Ni. The end point is reached when a non-permanent light violet color is obtained. The following precautions should be observed: (1) Start the Ni soln. at, or conc. to, a strength of 1-1.5%; (2) agitate thoroughly, especially towards the end; (3) use for the test fine and not too porous filter paper, as otherwise the Na₂S acts on the Ni nitroprusside passing through, and the Na nitroprusside reformed gives the violet test; (4) confirm the end point by another test 5 min. later; (5) titrate upon decidedly acid solns. This method is applicable to the common Ni salts, even in presence of Fe⁺⁺, Zn, Sn, Al, Pb, Mn. Ni nitroprusside is insol. in acids, and becomes dark green on drying, turning gray again on moistening, or on exposure to the air. It is very sol. in NH₄OH with which, however, it does not give the blue color of Ni-NH₄ salts, but instead, a yellowish brown. It turns lemon yellow with KOH, and dissolves in KCN. Co nitroprusside is red, and insol. in acids. It does not dissolve in KOH or NH₄OH. The latter changes it to dark brown, but it becomes lighter after a few minutes. Thus NH₄OH will sep. the Co from Ni nitroprusside. The Co salt not being sufficiently insol. the nitroprusside method is not delicate enough when applied to Co.

S. LEVY.

Application of a new reaction of copper, cobalt and nickel. GIUSEPPE MALATESTA AND ETTORE DI NOLA. Milan. *Boll. chim. farm.* 52, 819-23, 855-60(1913).—Uhlenhuth's reagent consists of 0.5 g. 1,2-diaminoanthraquinone-3-sulfonic acid in 500 cc. H₂O with the addition of 40 cc. NaOH soln. (40° Bé.). This reagent (red in color) gives a blue coloration with solns. of Cu salts when the reagent is not added in sufficient amt. to produce a violet coloration (due to blending of the red and blue colors); the soln. in which a blue coloration has been produced exhibits greenish fluorescence in reflected light. When a soln. of a salt such as NH₄Cl, NH₄NO₃, or MgCl₂ is added to the Cu salt soln. (either before or after addition of the reagent) a red color is obtained instead of the usual blue coloration; NaCl has no effect on the color reaction. When the Cu salt soln. (after addition of the reagent) is dild. with considerable H₂O the blue color is replaced by a red coloration. Aq. solns. of Co salts also give a blue coloration (and blue ppt. if concn. is sufficiently great) with the reagent; the reaction is sufficiently sensitive for the detection of 0.00002 g. Co in 1 cc. Addition of NH₄OH increases the intensity of color so that 0.000002 g. Co in 1 cc. may be detected; the sensitiveness of the reaction with Cu salts is not sensibly affected by the addition of NH₄OH. The coloration of a Co salt soln. is not changed by diln. with H₂O after addition of the reagent. The coloration due to a Co salt is not altered when NH₄Cl is added, so that this distinction, as well as the different behavior on diln. with H₂O, may serve to differentiate Co and Cu. NaCl has no influence on the coloration due to Co salts. Ni salts also give a blue ppt. with the reagent, the reaction being sufficiently sensitive to detect

0.0002 g. Ni in 1 cc.; contrary to the action of the Co and Cu ppts., the Ni ppt. flocculates readily. Addition of a small amt. of dil. NH_4OH soln. (5% soln., $d = 0.98$) increases the intensity of the coloration so that 0.00005 g. Ni in 1 cc. may be detected; a considerable excess of NH_4OH soln. (a vol. equal to that of the liquid to be tested) added subsequent to the addition of the reagent causes the blue coloration to become red. The latter phenomenon furnishes a means of differentiating Ni from Co and Cu. The influence of electrolytes, such as NH_4 , Mg and Al salts, on the coloration produced by Cu salts and the reagent may be nullified by the addition of a sufficient amt. of dil. NaOH soln.; a blue coloration which has been changed to red by addition of NH_4Cl may thus be restored and the application of the test may, therefore, be extended to solns. which already contain electrolytes which influence the coloration. Co may be detected in glass, smalt or porcelain, for instance, by treating a small portion of the pulverized material with a mixt. of HF and H_2SO_4 (or fusing with Na_2CO_3 and K_2CO_3), evapg. and dissolving the residue in aqua regia (or dissolving the fused mass in HCl), evapg. to dryness on a H_2O bath, dissolving the residue in H_2O , adding a little NH_4OH and an excess of dil. NaOH soln., filtering and adding several drops of the reagent to the filtrate. Several drops of dil. NaOH soln. are added to another portion of the filtrate; intensification of the blue coloration (or appearance of the latter, if not already present) shows that an insufficient amt. of NaOH soln. was originally added. Co, Cu and Ni may then be differentiated by the means previously mentioned. Metals may be quickly tested by placing on them a drop of HCl or HNO_3 , absorbing the acid liquid with a strip of filter paper, rendering the absorbed liquid alk. with 1 or more drops of dil. NaOH soln. and testing with 1 drop of a modified Uhlenhuth soln. (0.5 g. 1,2-diaminoanthraquinone-3-sulfonic acid, 100 cc. conc. NH_4OH soln., 360 cc. H_2O , 40 cc. of 40° Bé. NaOH soln.) proposed by M. and N. The reactions employed for differentiating Ni, Co and Cu have the same value when applied to a soln. absorbed by bibulous paper. Cu, for instance, may be readily detected when present in minute amt. in alloys of Pb, Sn and Sb. A drop of the alk. modified reagent of M. and N. gives an intense blue coloration when placed upon a plate of Cu or Co, so that the test may be applied direct without previous soln. in acid; a drop of the reagent placed upon a plate of pure Ni gives a scarcely perceptible coloration. The tests for differentiating Cu, Co and Ni may be applied direct to the liquid upon the metal object or this liquid may be either removed by a jet of H_2O or absorbed by bibulous paper before applying the differentiating tests. The coloration produced by a drop of the reagent upon a Ni object is so slight that this test has no value in the presence of Co and Cu. The foregoing tests are of especial value in case it is desired to investigate the comp. of objects such as jewelry, etc., in which procedure by soln., etc., is to be avoided; the distribution of Cu and Co (and Ni in certain instances) in the object under exam. may be detd. by applying drops of the reagent to various portions of the surface. H. S. PAINE.

New reaction of vanadium. VICENTE GARCÍA RODEJA. Univ. Valladolid. *Anales soc. españ. fis. quim.* 12, 305-9(1914).—Acid solns. of vanadates of the alk. metals give with "cupferron" (the NH_4 salt of nitrosophenylhydroxylamine) a dark red ppt. which flocculates to a spongy mass when agitated; this reaction is quite sensitive and a reddish coloration instead of ppt. appears when the content of V is less than 0.01 mg. per cc. The ppt. (and especially the coloration) disappears rapidly by boiling and slowly by prolonged contact with air at ordinary temp., just as in the case of the corresponding ppts. of other metals (Fe, Cu, etc., although the ppt. produced by Ti salts is more stable in the presence of air). The ppt. is sol. in alk. solns. and is slightly sol. in H_2O (this may be shown by washing the ppt. with H_2O and acidulating the filtrate, whereupon a reddish coloration appears). The products of oxidation of cupferron cause the pptn. of V to be incomplete; this is shown by the fact that the pro-

portion of V pptd. from a H_2SO_4 soln. of NH_4 vanadate decreased progressively with the increase in the time which had elapsed since the prepn. of the cupferron soln. Analogous results were obtained with a HCl soln. of NH_4 vanadate; the incomplete pptn. of V is due to the solvent action of the products of oxidation of cupferron which increase as the latter soln. is kept. Cupferron may be kept unchanged in a closed vessel containing a few pieces of $(\text{NH}_4)_2\text{CO}_3$, thus creating a NH_3 atm. By means of cupferron it is possible to obtain a reddish coloration when V (NH_4 vanadate in a soln. containing an equivalent amt. of H_2SO_4) is present in the proportion of 0.000001 g. in 1 cc.; this coloration is transitory and slow in appearing and finally changes to green, while the cupferron is oxidized in acid soln. If more than 0.000001 g. V per cc. is present the coloration appears within 1 min. (with gentle shaking). If more than 0.00001 g. V per cc. is present a brick red ppt. is obtained instead of a red coloration, while in the case of 0.000005 g. V per cc. the fine particles producing the coloration may be flocculated by sufficient agitation; this ppt. may be kept unchanged for a considerable period. The above test for V is more sensitive than most of the others which have been proposed. The red color produced by the action of conc. acids and vanadates, and especially the blue coloration produced with KCNS , is not obtained when V is present in a proportion less than 0.00005 g. per cc. The rose coloration produced by the action of H_2O_2 on vanadates in acid soln. is more sensitive than the preceding tests but is less sensitive than the reaction given by cupferron, since the coloration is scarcely perceptible when the V content is 0.000005 g. per cc.

H. S. PAINE.

Separation of vanadium and phosphorus with cupferron. VICENTE, GARCÍA RODRÍGA. Univ. Valladolid. *Anales soc. españ. fis. quim.* 12, 379-82 (1914).—The pptn. of V by cupferron is not quant. when V is present as the vanadic salt, even though a freshly prepd. soln. of cupferron is used (cf. preceding abstr.); the loss amounts to 0.7-1.9%. When V is present as the vanadyl salt cupferron in acid soln. produces a greenish brown ppt. which changes to reddish brown and flocculates to a spongy mass; the pptn. of V is quant. even when the cupferron soln. employed has been altered by standing after being prepd. Since, in most analytical detns., V is usually present as a vanadate of an alk. metal, it should be reduced to the vanadyl salt (V_2O_4 compd.) before pptg. with cupferron. The following procedure is proposed: Take a sufficient amt. of the neutralized alk. metal vanadate soln. to contain 0.2-1.0 g. V, add 5 cc. H_2SO_4 (dild. 1:5 with H_2O) and an excess of satd. SO_2 soln. (to reduce V_2O_5 to V_2O_4), boil and expel SO_2 with a current of CO_2 . Allow the soln. to cool, complete the vol. to 50 cc. and ppt. with a 5% cupferron soln.; add the latter slowly with const. stirring until several drops produce a white ppt. (nitrosophenylhydroxylamine, which is liberated when the cupferron comes in contact with an acid medium). Then add 2-3 cc. more of the cupferron soln., filter and wash rapidly with acidulated H_2O (the filtrate becomes turbid owing to oxidation of cupferron); dry the ppt. for a while at 90° , calcine until all organic substance is destroyed and weigh as V_2O_5 . The following procedure for sepg. V and P possesses about the same degree of accuracy as that recommended by Treadwell and is much more rapid. Acidulate the soln. under exam. with H_2SO_4 , add a satd. SO_2 soln., boil and expel excess SO_2 with CO_2 ; after cooling ppt. the V with cupferron as indicated above and weigh as V_2O_5 . The filtrate is evapd. on a H_2O bath, H_2SO_4 is expelled and the products of decomp. of cupferron are eliminated as much as possible; the residue is dissolved in acidulated H_2O and P is pptd. as NH_4Mg phosphate (Schmitz procedure). P may be detd. directly in the filtrate with greater rapidity and nearly the same degree of accuracy; add approx. 20 cc. satd. NH_4Cl soln. to 150 cc. of the filtrate and an excess of magnesia mixt. and follow the Schmitz procedure.

H. M. LANCASTER.

Analysis of spelter. W. B. PRICE, *et al.* *J. Ind. Eng. Chem.* 7, 547-8(1915).—Report of sub-committee on the analysis of non-ferrous alloys of the Div. Industrial Chemists and Chem. Engineers of the Am. Chem. Soc. The methods of analysis are those of Elliott and Storer (*Mem. Am. Acad. Arts and Sci.* 8, I, May 20, 1860) and Price (*C. A.* 3, 992), whose work has been checked and elaborated by the members of the committee.

ISADOR MILLER.

Determination of copper sulfate in commercial copper vitriol. GEORG INCZE. Budapest. *Z. anal. Chem.* 54, 252-5(1915).—The method consists in reducing the Cu and pptg. as CuCNS by addition of excess of a standard $\text{Na}_2\text{S}_2\text{O}_3$ soln. (19.878 g. per l.) containing 8 g. NH_4CNS per l., and titrating the excess $\text{Na}_2\text{S}_2\text{O}_3$ with I soln. (1.0178 g. per l.), using starch. Fe does not interfere.

GEORGE W. MOREY.

The determination of arsenic in slag lead and lead shot by hypophosphorous acid. L. BRANDT. *Z. öffentl. Chem.* 31, 66-71(1915).—A record of the exptl. work, with tabulated results, which lead to the conclusion that the pptn. of elementary As by means of hypophosphorous acid as variously given in metal analyses can be advantageously employed in the detn. of this element in slag lead and in lead shot. H. A. LEPPER.

Assay of gold-bearing cyanide solution. D. M. LEVY AND H. JONES. Inst. Min. and Met.; *Bull.* 128.—Transfer 453.6 cc. ($1/2000$ ton) of the soln. to be assayed to a 1250 cc. flask and add 15 cc. silver soln. (5 cc. for poor solns. and wash waters). The silver soln. is made by dissolving 36 grains AgNO_3 in water, adding NaCN till ppt. just dissolves, and diluting to 2500 cc. Now add 10 cc. NaCN (10% soln.) and then 5 cc. of Na_2PbO_2 (to 65 g. Pb(OAc)_2 in water add NaOH soln. till ppt. just dissolves, then dil. to 2500 cc.) and shake. Add 20 g. Zn shavings and boil gently for 30 min., filter at once through a 9 in. paper, rejecting the clear filtrate. To the residual Zn shavings add a little (about 20 cc.) water, then 70 cc. com. HCl . After complete soln. of the Zn, pour through same filter, wash both flask and filter thoroughly, transfer wet to an assay crucible, place in furnace till carbonized, withdraw from furnace and add the following flux: Pb_3O_4 12.5 g., $\text{Na}_2\text{B}_4\text{O}_7$ 22.5 g., Na_2CO_3 12.5 g., NaCl 2.0 g., flour 2.0 g., powdered glass 2.0 g., KNO_3 2.0 g. Replace in furnace and run down in the usual manner (20 to 30 min.). Cupel the button in a magnesite cupel, roll the bead and part in the usual way.

E. G. R. ARDAGH.

Method of making mineralogical analysis of sand. C. W. TOMLINSON. *Bull. Am. Inst. Mining Eng.* 1915, 947-56.—The samples analyzed weighed 290-340 g.

By the method 4 samples can be analyzed simultaneously in 33 working hrs. (1) *Sizing*. Use nest of sieves, 10, 20, 40 and 100 mesh. (2) *Weighing of sizes*. If any group amounts to less than 1% of the whole, it may be neglected in the analysis. (3) *Preparation of heavy solution*. An excellent classification of the sand which passes the 20-mesh sieve may be made by means of heavy solns. A soln. of d. 2.9 will sep. practically all the dark silicate minerals from the others. The most satisfactory soln. to use is potassium mercury iodide in H_2O . Details of manipulation and discussion of results obtained with heavy solns. are given. (4) *Hand sorting*. This is done with the material which passes 20 mesh. (5) *Weighing of separates*. (6) *Microscopic analysis of heavy solution separates*. A good hand lens is sufficient for this purpose, and a black sheet with a square pattern in white makes a satisfactory background for quant. detn. (7) *Computation of analyses*. From the above detns. the % comp. is given as "igneous rocks, shale group, quartz group, dolomite group, feldspar, heavy minerals, and not examined." Tables of results of detns. and sample reports are given.

E. W. BOUGHTON.

Notes on the practical testing of working cyanide solutions. E. H. CROGHAN. *J. Chem. Met. Soc. S. Africa* 15, 271-6(1915).—In testing a working soln. the usual procedure is to add a little KI, titrate 50 cc. with standard $AgNO_3$ (6.253 g. per l.; 1 cc. = 0.01%) to turbidity for "free cyanide," then without filtering, to add phenolphthalein and det. "protective alkalinity" with standard acid. On another 50 cc. total cyanide is detd. by adding excess of NaOH containing KI and titrating with standard $AgNO_3$. Clennell's method (Chemistry of Cyanide Solutions) reverses the order of the tests. "Total cyanide" is detd. in the same manner. To another 50 cc. add about 0.2 cc. excess of $AgNO_3$, then a slight excess of $K_4Fe(CN)_6$ followed by phenolphthalein, and det. "protective alkalinity." To a third 50 cc. add the amt. of acid indicated, then 5 drops KI and titrate with $AgNO_3$ for "free cyanide." In the $AgNO_3$ titrations some take the end point as the appearance of a *white* turbidity; others continue the addition to the appearance of a *yellow* tinge. A table is given of results of the above tests on 22 working solns. In the ordinary method for "free cyanide" the white end point agrees pretty closely with the *yellow* end point in Clennell's method, while the *yellow* end point gives very nearly the "total cyanide," especially in weak solns. But carrying the addition of $AgNO_3$ in the ordinary method to the *yellow* end point reduces materially the amt. of "protective alkali" indicated. For "protective alkalinity" Clennell's method gives a result falling between those obtained with *white* or with *yellow* end point.

E. WALLER.

Reduction of copper oxide in alcohol vapor in reducing sugar determinations and copper analysis. A. WEDDERBURN. *J. Ind. Eng. Chem.* 7, 610-1(1915).—Collect Cu_2O on an alundum filtering crucible using Spencer's filtering funnels with suction. Wash thoroughly with hot H_2O followed by alc. Heat to redness to destroy org. matter and allow to cool until redness just begins to disappear and then immerse in an atm. of alc. vapor as follows: Place a pipe-stem or silica tripod in a 400 cc. beaker (metal) and put in strong alc. so as to cover the bottom for 1 cm. and cover the beaker with a watch glass. Heat the alc. to boiling and continue heating until the vapors begin to condense on the cover glass. Now place the hot crucible on tripod and replace cover glass. If the crucible be too hot, the alc. will ignite. Allow the alc. to continue to boil for a moment and then remove the source of heat. The crucible is kept in the covered beaker until it is cooled to a temp. a little above that of the alc. vapor (time, 3-4 min.). Remove and cool in a desiccator. The reduction to metallic Cu is almost instantaneous and complete.

ISADOR MILLER.

Quantitative determination of phosphine. H. RECKLEBEN. *Leipzig. Z. anal. Chem.* 54, 241-52(1915).—A comparison of the value of various solns. for the absorption

of PH_3 from H-PH_3 mixtures. The following give good results, and the amt. PH_3 can be detd. directly without intermediate absorption: 0.5 N I-KI soln., HClO soln., HBrO soln., concd. KIO_3 soln., 0.1 N AgNO_3 soln., and both Hg^+ and Hg^{++} salt solns. The following reagents also give as good results and in some cases a more rapid absorption: 0.16 N Cl soln. (too strong may cause explosion), satd. Br soln., acidified 0.2 N KBr-KBrO_3 soln., ammoniacal AgCl soln., acidified CuCl soln., acidified 0.5 N KMnO_4 soln.; with each of these a second absorbent is necessary to remove gas taken up from the soln. (Cl , Br , NH_3 , HCl , or O , resp.). Other reagents ($\text{K}_2\text{Cr}_2\text{O}_7$, FeCl_3 , CuSO_4 , Fehling soln., H_2SO_4 , HCl , etc.) tried did not give good results. G. W. M.

Determination of nitrogen according to Kjeldahl. ORTO NOLTE. Göttingen. *Z. anal. Chem.* 54, 259-62(1915).—In the detn. of N in organic substances by the Kjeldahl method, addition of sugar was found to be without influence on the result with some easily decomposable substances, i. e., aniline sulfate, betaine hydrochloride, $\text{K}_4\text{Fe}(\text{CN})_6$, hippuric acid, pyrrole, mustard oil, AgCNS , Me_3NHCl ; it caused a slight loss of N in some more difficultly decomposable substances, i. e., acetanilide, antipyrine, uric acid, caffeine, AgCN ; and gave much better results with some other decomposable substances, i. e., $(\text{C}_6\text{H}_5)_2\text{NH}$, methylindole, pyridine hydrochloride, Me_2NBr .

GEORGE W. MORREY.

The determination of selenium in organic compounds. H. BAUER. *Ber.* 48, 507-8(1915).—Heat 0.2-0.3 g. of the material with fuming HNO_3 in a sealed tube for 5 hrs. at 250° . In some cases longer heating is necessary. Transfer the contents of the tube to a 1 l. round-bottom Jena flask, washing out the tube with the smallest possible amt. of H_2O . Add 100 cc. of concd. HCl and some glass beads. Heat under a reflux condenser until no more nitrous fumes are noticeable and the liquid is colorless. This will require 1-3 hrs. Filter into a beaker, add 3 g. Na_2SO_3 and heat on the water bath until the Se has settled as a black ppt. If the soln. does not smell of SO_2 , add more Na_2SO_3 . Filter off the pptd. Se on a Gooch crucible, wash, dry at 110 - 120° and weigh.

E. W. BOUGHTON.

Bromine method of estimating phenol. W. VERSFELD. *Analyst* 40, 281-3 (1915).—V. recommends the following method: Place a portion of the soln. containing about 0.05 g. of phenol in a glass-stoppered flask of 500 to 1000 cc. capacity, and dil. with about 50 cc. water. Add 5 cc. strong HCl and 100 cc. hypobromite soln. (prepd. by satg. 100 cc. 0.5 N NaOH with Br water, boiling until quite colorless and dilg. to 1 l.), shake the flask well and allow to stand 15 min. Raise the stopper sufficiently to pour in about 20 cc. KI soln. (10%), shake the flask again, let stand for 5 min., dil. to 300 or 400 cc., and titrate with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$, using filtered starch as indicator. A control is carried out in the same way. The difference in cc. between control and test multiplied by 0.156746 = % phenol if 1 cc. was used. The $\text{Na}_2\text{S}_2\text{O}_3$ is standardized by adding 20 cc. 0.1 N $\text{K}_2\text{Cr}_2\text{O}_7$ to a mixt. of 10 cc. KI (10%) and 5 cc. strong HCl , and titrating the I liberated. Br water containing KBr is fairly permanent and may be used instead of the hypobromite soln.

P. B. DUNBAR.

The determination of methyl alcohol in the presence of ethyl alcohol. W. A. R. WILKS. Sudan Govt. Wellcome Tropical Research Labs., Khartoum, Chemical Section, *Bull.* 1, Oct., 1914.—An investigation of the standard method of detg. MeOH in presence of EtOH by weighing the CO_2 produced on oxidizing the MeOH by H_2SO_4 + $\text{K}_2\text{Cr}_2\text{O}_7$ (Thorpe and Holmes, *J. Chem. Soc.* 85, 1(1904)) led to the conclusion that the correction of 0.01 g. CO_2 for each g. EtOH present is not a constant. By using less H_2SO_4 , or adding borax to lessen the intensity of the reaction the correction factor may be decreased but never becomes a constant. W. recommends the following procedure by which the correction factor is reduced to 0.0040: Dissolve 30 g. $\text{K}_2\text{Cr}_2\text{O}_7$ in 150 cc. water, cool in a freezing mixt. paying no attention to the sepn. of $\text{K}_2\text{Cr}_2\text{O}_7$ crystals,

add 50 cc. of this aqueous alc. mixt., and then in small quantities at a time run in 20 cc. H_2SO_4 in 20 cc. H_2O , the acid mixt. having been first thoroughly cooled in ice and salt. The other usual details of procedure are presumably unchanged.

E. G. R. ARDAGH.

Detection of methyl alcohol in ethyl alcohol. UMBERTO PAZIENTI. Padova. *Ann. chim. applicata* 3, 279-81 (1915).—Most methods are based on oxidation of the 2 alcs. by appropriate means, fractionating the products and testing the different fractions. Schryver detects HCHO in the liquid without fractionating. But his test (a red color produced by the HCHO on adding to 10 cc. of the liquid containing it 2 cc. of 1% phenylhydrazine hydrochloride recently prepd. and filtered, and 1 cc. of a freshly made 5% $\text{K}_3\text{Fe}(\text{Cn})_6$ soln. and 5 cc. concd. HCl) loses its power when considerable quantities of HCHO are present. P. suggests the following modification: Dil. 5 cc. of the sample to 50 cc., put into a 250 cc. flask containing 3 g. $\text{Na}_2\text{S}_2\text{O}_8$ and 10 cc. 20% H_2SO_4 , close the flask with a ground-glass stopper carrying a tube joined to a reflux condenser. Bring to a boil, and when it begins to distil, collect in fractions of about 2 cc. By testing the 5th fraction with Schryver's reagent 0.001 part MeOH may be detected. Treating the distillate directly without fractionating, there may be detected 4% MeOH in the EtOH . If the color is not distinct, it is well to repeat the reaction upon the distillate more or less dild. with H_2O .

EDGAR T. WHERRY.

Solubility of magnesium carbonate in natural waters. ROGER C. WELLS. *J. Am. Chem. Soc.* 37, 1704-7 (1915).—Under atmospheric conditions it appears possible to attain practically the same equil. state in a soln. satd. with $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$, whether one starts with a soln. contg. an excess of $\text{Mg}(\text{HCO}_3)_2$ or with pure trihydrate and H_2O , but adjustment occurs very slowly. The soln. finally contains 0.36 g. Mg and 1.01 g. CO_2 per l. at 20° . The solubility of magnesite is much smaller, 0.02 g. Mg and 0.07 g. CO_2 per l. Certain natural waters exposed to the atm. appear to be supersatd. with respect to magnesite, but none approaches very closely the satn. point of $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$.

E. B. MILLARD.

Corundum: its occurrence, distribution, exploitation, and uses. A. E. BARLOW. *Canada Dept. of Mines Memoir* 57, 316 pp. (1915).—Aluminium is an essential constituent of all important rocks except sandstones and limestones, and because of its affinity for O, it is always found in nature in combination. Corundum-bearing rocks are widely distributed. Evidence points to the fact that all the deposits of corundum which are commercially valuable are primary crystns. from igneous magmas containing an excess of Al, confirming the results of Morozewicz (1889). The corundiferous rocks of eastern Ontario are of syenitic, dioritic, and gabbroic type and appearance. The feldspathic constituent varies from micropertthite to bytownite; nepheline and scapolite often accompany or replace the feldspars. The nepheline- and related alkaline-syenites with which the principal occurrences of corundum are associated show an extreme and rapid variation in comp. No other class of rocks show an equally great diversity of types within such short distances. The normal phase is a rock composed almost wholly of feldspar, chiefly a micropertthite, prevailing albitic. All the rocks in the corundum-bearing syenitic complex are differentiation products of one highly aluminous magma.

These rocks are usually very poor in Fe-Mg constituents and differ from the great majority of the occurrences of similar rocks in that the augite, which is usually present, is replaced by biotite or hornblende or both. The Ontario occurrences of corundum show clearly its development as a primary constituent from a highly aluminous silicate magma as one of the first products of crystn. Chem. analysis shows that the occurrences conform closely to the law of Morozewicz: that the development of corundum in the magma is dependent on the ratio of the Al_2O_3 to the sum of the other bases. In the neighborhood of belts of corundum-bearing rocks the limestones have been thoroughly metamorphosed and rendered cryst. and impure by the secondary development of silicates. 42 mineral species have been recognized among the products due to the direct action of the magmatic waters accompanying the intrusion of the Laurentian granite batholiths. Amphibolites have originated in 3 entirely different ways: (1) from the metamorphism and recrystn. of sediments; (2) by alteration of igneous intrusions and (3) by the metamorphic action exerted by the granite batholiths on the limestones through which they cut. A remarkable similarity was found in the chem. comp. of the corundum-bearing rocks occurring in such widely separated localities as Canada and Russia. Muscovite seems to have resulted from the alteration of corundum, this change being connected with some phase of pneumatolytic or vein action which immediately preceded the complete solidification of the enclosing rock from the molten magma. Corundum is one of the most unalterable of substances when subjected to ordinary processes of weathering. A detailed statement (107 pp.) of the distribution of corundum is given; it includes all the known deposits of the mineral occurring in amts. of economic and geological importance. The list shows that it is quite universally and plentifully distributed. A chapter on the production of artificial corundum as well as one on the mining and milling of corundum together with a compilation of statistics concerning the mineral is included. A complete bibliography of Canadian corundum is given.

R. L. SIBLEY.

The chemical composition of some minerals. I. FERRUCCIO ZAMBONINI. Univ. Turin. *Atti accad. sci. fis. nat. Napoli* [2] 16, 25 (1914).—On the basis of his own and other mineral analyses Z. concludes that the minerals of the nepheline group (except the chloride-sulfates and carbonate-silicates, which are characteristic of the cancrinite subgroup) contain the following individuals: $K_2Al_2Si_2O_8$, $Na_2Al_2Si_2O_8$, $CaAl_2Si_2O_8$, Na_2SiO_3 , and $NaAlO_2$. Similarly the constituents of augite (monoclinic pyroxene) were found to be $R^{II}SiO_3$, $R^{II}R^{III}_2O_4$ and $R^{II}R^{III}_2(SiO_3)_4$ in which $R^{II} = Ca, Mg, Fe, Mn$, and Na ; $R^{III} = Al, Fe^{III}$ and Cr^{III} . The rhombic pyroxenes (enstatite, hypersthene) consist of metasilicates of di- and trivalent elements and of an aluminate. The triclinic pyroxene babingtonite was found to be a polymorph of enstatite-hypersthene; Ca, which is of secondary importance in the latter, occurs in larger amts. in the former. Triangular diagrams are given for the individual minerals.

E. J. WITZEMANN.

Nephelite crystals from Monte Ferru, Sardinia. H. S. WASHINGTON AND H. E. MERWIN. *Geophys. Lab. J. Wash. Acad.* 5, 389-91 (1915).—Nephelite crystals occurring in miarolitic cavities in trachytic phonolite (described by W., *C. A.* 9, 1734) have the unusually high value $\epsilon = 0.841$ and the low values $\epsilon = 1.529$, $\omega = 1.532-3$. The comp., detd. on less than 0.2 g. and corrected for 7.51% insol. augite and titanite inclusions, is SiO_2 43.34, Al_2O_3 33.45, Fe_2O_3 2.60, CaO 0.87, Na_2O 16.28, K_2O 3.46, sum 99.99%, the corresponding mol. ratio being $SiO_2:Al_2O_3:Na_2O = 2.26:1:0.99$.

E. T. W.

Artificial crystals of gypsum. C. PERRIER. Univ. Turin. *Atti accad. Lincei* 24, I, 159-63 (1915).—Limestone kept for 2 yrs. in an $FeSO_4$ soln. was gradually converted into gypsum. Because of the slowness of the process the gypsum crystals were obtained in a large variety of forms, measurements of which are given.

E. J. WITZEMANN.

The monticellite-like mineral in meteorites and oldhamite as a meteoric constituent. GEORGE P. MERRILL. U. S. Nat. Mus. *Proc. Nat. Acad.* 1, 302-8(1915).—A colorless, biaxial, weakly birefringent mineral, first noted in chondritic meteorites by Tschermak in 1883, and referred by him doubtfully to monticellite, has been further examd. Its *ns.*, detd. by F. E. Wright, are $\alpha = 1.623$ and $\beta = 1.627$, birefringence less than 0.005. The only terrestrial mineral with these properties is francolite, $(\text{CaF})_2\text{-Ca}_3(\text{PO}_4)_2\text{-CaCO}_3 + \text{H}_2\text{O}$, although this is optically — while the unknown mineral is +. Microchem. tests showed that the mineral dissolves readily in acids, especially HNO_3 , and in the soln. Ca and P, but no other constituent, could be detected. After removing the metallic portion and H_2O -sol. constituents of a sample of the Alfianello meteorite, dil. HCl extd. 0.344% CaO and 0.08% P_2O_5 , which is a much higher ratio of Ca:P than in francolite. This mineral has been noted in at least 16 meteorites, and supposed occurrences of apatite in meteorites are probably the same mineral, which may be relegated doubtfully to francolite. To detect oldhamite (CaS) in meteorites powd. samples were b. in H_2O and tested qualitatively for Ca. Positive reactions were obtained in 19 cases, doubtful in 1 and negative in 3. While the presence of a sol. Ca compd. does not necessarily indicate the presence of oldhamite, the liberation of H_2S in some of these cases makes its presence more certain. Oldhamite is therefore to be regarded as a fairly common constituent of meteorites, although it may be irregularly distributed in a given fall, and may not be recognized because of alteration or loss during grinding of sections.

E. T. W.

To what extent is chalcocite a primary, and to what extent a secondary mineral in ore deposits? L. C. GRAYTON, J. D. IRVING, T. T. READ, F. L. RANSOME, W. LINDGREN AND J. F. KEMP. *Trans. Am. Inst. Mining Eng.* 48, 194-200(1915).—The chief problems, as stated by G., are to distinguish primary and secondary chalcocite and to determine the conditions under which secondary chalcocite is formed, especially the relation of the process to the ground water level. I., describing expts. of H. V. Winchell, points out that pyrite immersed in CuSO_4 soln. remains bright, but, if SO_2 is added, the pyrite becomes thickly coated with dense gray chalcocite. Read suggests that SO_2 is really an oxidizing rather than a reducing agent, because of the presence of so much O in it [apparently confusing quantity with quality. ABSTR.]. G. points out that the reaction between pyrite and CuSO_4 without SO_2 , though exhibiting no measurable progress in a few weeks, may advance to an important degree in the course of a short time measured in geologic units. By agitation and increasing the temps. it is possible to hasten such reactions, and the reaction has actually yielded chalcocite in the absence of SO_2 under such exptl. conditions. As no oxidation can take place without corresponding reduction, whether the formation of a given mineral is to be classified as either depends on the point of view. Sooty chalcocite, often considered as a criterion of the secondary nature of the mineral, is really decomposing and disintegrating material. Certain chalcocites previously described as primary have been found to contain bornite nuclei in such arrangement as to indicate their secondary character. Ransome confirms G.'s views as to the nature of sooty chalcocite. L. points out that primary chalcocite in fine crystals formerly occurred at Bristol, Ct., and K. calls attention to the occurrence of crystd. bornite in the same region.

E. T. W.

Geology and mineral deposits of the National Mining District, Nevada. W. LINDGREN. U. S. Geol. Survey, *Bull.* 601, 58 pp.(1915).—The principal point of interest in this district is the wonderfully rich shoot of the National mine. The veins of the district are essentially Ag veins of moderate tenor, but the very rich vein mentioned has furnished over \$3,000,000 in Au, which occurred as electrum, containing about 50% Ag. The origin of this Au remains a mystery, but the mineralization of the veins

seems to have been due to deposition by hot ascending waters during a thermal epoch following the eruption of rhyolite near which the veins are chiefly found. Stibnite and cinnabar have been noted in the quartz, but pyrite is scarce. Some marcasite has been deposited as a secondary mineral. R. C. WELLS.

Structure of the Cuyuna iron ore district of Minnesota. CHARLES A. CHENEY, JR. Madison, Wis. *Eng. Mining J.* 99, 1113-5(1915).—The principal factors in detg. the location of ore bodies in this district have been: on the north range, drag folding; on the south range, the original chem. comp., the degree of metamorphism, and the effects of preëxisting topography. The absence of greenalite, an Fe silicate present in the Biwabik formation of the Mesabi district, does not necessarily indicate that the Fe formations of the 2 regions are distinct; since pptn. of Fe as silicate or carbonate depends on the relative amts. of CO_2 present, the absence of the silicate in the Cuyuna region may merely indicate a difference in conditions of contemporaneous deposition of the same formation. E. T. W.

Mineralogical and petrographical investigations in the valley of the "Chisone" (Alpi Cozie). An interesting variety of gneiss from Prali. EMANUELE GRILL. Florence. *Atti accad. Lincei*, 24, I, 251-5(1915).—The rock has the appearance of quartzite, but the presence of a considerable amt. of alk. feldspar and mica characterize it as true gneiss, which G. calls a "microcrystalline muscovitic microclinal gneiss." E. J. WITZEMANN.

Manganese concretions in Mesozoic deep-sea deposits of Borneo, Timor and Rotti, their significance and mode of formation. E. A. F. MOLENGRAAF. *Verslag K. Akad. Wetenschappen* 23, 1058-73(1915).—Concretions of Mn oxides are found at the bottom of all oceans and are characteristic of abyssal deposits. The analysis of various specimens shows them to consist of about 60% MnO_2 , 10% MnO with varying amts. of Na_2O , CaO , BaO , CoO , Fe_2O_3 , Al_2O_3 and SiO_2 . The various places on land where these concretions have been found are listed, and their probable mode of formation is discussed at length. L. H. ADAMS.

Vapor pressure of arsenic trioxide. H. V. WELSH AND L. H. DUSEHAK. U. S. Bur. of Mines, *Tech. Paper* No. 81, 21 pp. (1915).—A knowledge of the vapor pressure of As_2O_3 is necessary for the proper design and management of equipment for its condensation, e. g., from metallurgical smoke. By the air satn. method of Regnault and Magnus, the v. p. of As_2O_3 was found to range from 0.000266 mm. at 110° to 89.1 mm. at 300° , corresponding to 0.000386 lbs. to 1441 lbs. of the oxide per 1000 cu. ft. gas. The "total heat of sublimation" decreases from 27,390 g. cal. (15°), at 110° , to 26,500 g. cal., at 290° , the "inner heat of sublimation" from 27170 g. cal., at 110° , to 25,380, at 290° . The probable error, both in this and the v. p. detns., is $\pm 1\%$. The m. p. of octahedral oxide is provisionally fixed at $251^\circ \pm 1^\circ$, that of the monoclinic variety at 313° . The latter is stable above 100° . Rather rich arsenical dust from the main flue of a Cu smelter showed a v. p. of about half that of the same amt. of pure material, either because the oxide was present in the monoclinic form, in solid soln. or in chem. combination with other constituents of the dust. W. B. J.

Smelting storage-battery sediment. W. C. SMITH. *Eng. Mining J.* 100, 18 (1915).—As a result of expts. that are outlined and briefly discussed the following procedure is recommended: Add 75 lbs. or less to each charge; wet charge thoroughly; heat sediment in roasting furnace or kettle until it turns yellow (to convert PbO_2 into PbO and O) and then charge into furnace as Pb ore. F. W. SMITHER.

Concentration of gold in bottoms in the copper converter. H. F. COLLINS. *Met. Chem. Eng.* 13, 446-7 (1915).—The method, devised for recovering the Au in converter Cu not rich enough to warrant electrolytic refining, depends on the incomplete oxidation of white metal to "pimple" metal and "bottoms," and sepn. of the latter before completing the oxidation. It has been adapted to 3-ton, acid-lined converters. The success of the operation depends on not losing too much time in skimming and not adding too much scrap after skimming, so that the reduced Cu is at a temp. above the m. p. of the pimple metal. It is necessary to hit the point of "white metal" with considerable nicety before the final skimming prior to commencing the blowing for bottoms. In practice it is easy to recover 70% of the Au originally existing in the charge in the form of bottoms, amounting to 9% of the total wt. of converter Cu produced, and 25 times as rich. F. W. SMITHER.

The testing of ores for the cyanide process. WELTON J. CROOK. *Chem. Eng.* 21, 256-7 (1915).—C. describes simple quant. tests to det. the "soluble" and "latent" acidity of an ore by titrating with standard $H_2C_2O_4$ and NaOH solns. By means of such tests the proper amt. of alkali necessary to neutralize the "cyanicides" present may be detd. Cyanicides are described as substances which decompose active cyanides, forming compds. which are not solvents of Au and Ag. L. A. TOUZALIN.

Preferential flotation. O. C. RALSTON. *Mining Sci. Press* 110, 980-4 (1915).—A review (largely a patent compilation) of proposed or operating preferential flotation processes. L. A. TOUZALIN.

Flotation tests on ores from Bisbee and Cobalt. H. J. FRENCH. *School of Mines Quart.* 36, 57-67 (1914).—Every ore capable of concn. by this method has its own set of optimum conditions. It seems probable that many of the points developed in the

expts. detailed are to some extent applicable in many other cases. Trials were made as to the kind of oil, its amt., the presence and proportion of acid, time of agitation, temp., and size of the particles. The conclusions were that the best in these cases is pine tar oil (sp. gr. approx. 0.98) with addition of 0.3% concd. H_2SO_4 reckoned on the wt. of the H_2O in the pulp, and agitation for at least 10 min. at a temp. of 65° . Material of 100- to 150-mesh worked satisfactorily. When coarser than 65-mesh the process was unserviceable. Agitating and skimming and again agitating and skimming without adding more oil was more effective than one agitation and skimming, using more oil at once.

E. WALLER.

Cyanidation of low-grade sulfide ores in Colorado. I. H. C. PARMELEE. *Met. Chem. Eng.* 13, 421-5(1915), cuts.—Conditions in Clear Creek and Gilpin counties, the location and construction of the Argo mill and the difficult problems presented are discussed and results of 18 months' operation reported in detail. A flow sheet shows the operations to be as follows: stamping with 1050 lbs. stamp in cyanide soln., primary concn. to remove Pb, Fe and Cu sulfides, regrinding the sand tailing in a tube-mill, agitation, secondary concn. to remove the sulfides unlocked in regrinding, thickening, filtration and pptn. on Zn. The tests conducted at the Argo mill indicate that the concentrates can be profitably cyanided, but at present the mill is not equipped for the work. The Ag recovery probably would not exceed 60%, but the Au extn. would be satisfactory. The value of the Au recovered as bullion would exceed its value in the form of concentrate, and the difference would be more than the cost of treatment. The residue from cyanide treatment would still form a low-grade shipping product. Balancing all the factors involved, the net result of cyaniding concentrates and shipping the residue to the smelter would show an increased profit as compared with the present practice of shipping direct. The successful operation of a custom cyanide mill like the Argo depends on exhaustive preliminary tests, both chem. and physical; attention to numerous details; a careful balancing of causes and effects to secure the most economical av. conditions; and an assured steady ore supply. (Cf. Pearce, C. A. 9, 192.)

F. W. SMITHER.

Notes on Homestake metallurgy. A. J. CLARK. *Bull. Am. Inst. Min. Eng.* 1915, 1381-1400.—Changes and comments on the method already described (C. A. 7, 960) are noted. The ore is exceptionally heavy, av. sp. gr. 3. Hornblende crystals make it difficult to crush, but aid in leaching. Inside amalgamation is practiced. The amalgam is retorted in oil-fired retorts 3 times per month, the bullion being melted in coke-fired furnaces. In cyaniding, protective alkali has been practically eliminated, only enough CaO being added to neutralize the ore. The "strong" soln. is strengthened in accordance with the detn. on the weak soln. to keep it up to its best working strength. The sand is leached in vats; at intervals air is forced into the false bottom, below the filter canvas. About 75 cu. ft. of O is absorbed to a ton of ore, before its reducing action is corrected. Air followed by a water wash shows $\text{Ca}_2\text{S}_2\text{O}_7$ in the effluent. Air followed by cyanide shows thiocyanate at first, and free cyanide does not appear for some time. After extn. the sand shows no oxidation. The slimes are treated in Merrill presses with double cloths—alternate leaching and aerating. Efficient extn. seems to depend more upon the vol. of the soln. passed through than upon its strength or period of contact. The working strength is detd. by the ability to ppt. the effluent. Pptn. is by Zn dust. Double cloths are used in filtering, the outer one being burned when the press is cleaned and the ashes sent to the refinery, so washing of cloths is eliminated. Treatment with acid is advocated as causing less danger of stack losses, insuring fluid slags, and requiring less time. Low grade ppt. is briquetted and charged in the blast furnaces. High grade is cupelled directly. E. WALLER.

Smelting methods at Magistral, Durango, Mex. R. W. BISSELL. *School of*

Mines Quart. 36, 22-9(1914).—The output of the group of mines is of 4 different kinds: (1) Quartz pyrite (about $\frac{1}{4}$ pyrite); (2) basic (in which these proportions are practically reversed); (3) red ore (siliceous, containing 25% Fe_2O_3 , and 20% calcite); (4) spar ore (a little more than half calcite and about 10% pyrite). All contain Cu, Au and Ag. Most of the Cu is in the basic ore, most of the Au in the quartz pyrite. Av. content of Cu is 0.9%, of Au 0.56 oz., of Ag 0.25 oz. Treatment is a partial pyritic smelting operation in steel water-jacket blast furnaces 40 X 168 in., the product being a mat containing the values; 15 or 16 tons are concd. to 1 ton mat, carrying 15 to 18% Cu, and \$160 to \$180 in precious metals. Cu recovery is 84.7%, Au recovery 89%. The coke charge varies; at times it has been as low as 5%, but the average is nearer 12%. Operations have been suspended because of political troubles. E. WALLER.

The British Columbia Copper Co.'s smelter, Greenwood, B. C. F. K. BRUNTON. *Bull. Am. Inst. Min. Eng.* 1915, 1401-18.—The plant has successfully smelted the lowest grade Cu ore in America, having an av. content 0.85% Cu. By mixt. of the sulfide ores, and addition of a low grade siliceous Au ore, mats containing 30-45% Cu were obtained. Treating this in converters yielded blister Cu carrying about 7 oz. Au and 30 oz. Ag per ton. Details are given of construction, power, labor, expenses, etc. E. WALLER.

Powdered coal as fuel for metallurgical furnaces. ANON. *Rass. min.* 42, 109-10 (1915).—A brief review. CHAS. A. ROULLER.

Oil-fired metallurgical and shop furnaces. F. B. DUNN. *Elec. Power and Gas* 34, 297, 317(1915); cf. *C. A.* 9, 523, 1389.—A brief review of furnaces for these purposes designed for oil firing. Designs are given for small smelting, refining and annealing furnaces. Data on one furnace at a rolling mill showed the consumption of oil per ton of Fe to be 35-47 gal. and the waste heat was sufficient to furnish steam for the engines to drive the rolls. Low pressure air has been found to be the best atomizing agent. The Riverall blast furnace using oil as fuel is described. A 50-ton smelter at Tropic, Cal., has been successfully demonstrated. The operation of the Dow oil smelting furnace is also described. Data on 3 furnaces located in different parts of the country show that it produces economically a better grade of pig than coke furnaces.

W. E. RUDER.

Influence of impurities on zinc. C. C. FREEMAN. *Monthly J. Chamber of Mines of West Australia*, Feb., 1915; *Engineering Mining J.* 99, 990(1915).—Although in many parts of the world Zn dust is to a large extent replacing shavings as a precipitant for precious metals from cyanide solns., the shavings are still almost universally used in Australia. In small mills the relatively low cost of the installation necessary for pptn. by Zn shavings would outweigh any advantages that would accrue from the use of Zn dust as the precipitant, and in the case of the larger plants which are already equipped with efficient units of the former type, it is a matter of expt. and calcn. to det. whether or not the advantages claimed for Zn-dust pptn. warrant a change to the latter system. Most of the English Zn smelters aim at the production of spelter suitable for making a good quality of brass, for which purpose little Pb is permissible, and such spelter cannot be conveniently rolled. Many of the Continental works treat Zn ores and concentrates containing appreciable amts. of Pb, and the resulting spelter, after refining, usually contains from 1 to 1.5% of Pb. The rolling qualities of spelter are affected to a marked degree by the impurities present. Moderate amts. of Pb render Zn malleable and ductile; amts. up to 1.5% permit good rolling. With more than 1.5% Pb, Zn becomes tender; and although it can be successfully rolled when it contains 3% of Pb, the sheets are very tender and liable to crack. Fe reduces the malleability of Zn and makes it harder and more brittle; up to 0.125% Fe is not injurious, but above this the bad effects become apparent; over 0.2% Fe seriously interferes with rolling.

If much ZnO is present the spelter will become brittle and difficult to work. Cd up to 15% does not interfere with rolling, while Cu, Sn and As render Zn hard and brittle. At ordinary temps. Zn is quite brittle, between 100° and 150° it becomes malleable and ductile, and above 150° it again becomes brittle, and at 200° can be reduced to a powder by pounding. The relatively coarse cryst. structure of cast Zn is destroyed by rolling or hammering, and the d. of the wrought metal is about 7.25, compared with 7.05 when cast. Wrought Zn heated to between 100° and 150° retains its malleability and ductility after cooling. The methods in use for producing Zn shavings and Zn ribbon are briefly discussed.

F. W. SMITHER.

Microscopic examination of steel. ANON. U. S. Ordnance Department Document No. 1961(1915); illus.—As a guide for ordnance inspectors, a clear, concise explanation is given of the important characteristics of steel, including its thermal and mechanical treatment, its structural compn., the impurities likely to be present and the common defects. The cause of failures that are likely to occur in service are discussed in detail, especially with reference to the following typical examples of which photographs are shown: 10-in. rifle, crack in tube caused by a fold in forging; 14-in. gun lever, fracture due to improper heat treatment, the photomicrograph showing segregated ferrite and an abundance of slag; 12-in. gun, fracture due to a zone of streaked metal and slag in the original ingot.

JULIAN S. GRAVELEY.

The hardening of metals. R. HADFIELD. *Trans. Faraday Soc.* 10, 207-11(1915).—The opening address before the Faraday Soc., Nov. 23, 1914, in a general discussion on the hardening of metals. A specimen of ancient Indian steel was shown which contained 0.7% C with low Si, S, P and Mn. The steel was soft and of pearlitic structure when found, but it was possible to harden it exactly as in the case of a piece of modern steel.

W. T. HALL.

The hardening of metals by quenching. C. A. EDWARDS. *Trans. Faraday Soc.* 10, 248-50(1915).—The theory advanced by Carpenter and Edwards (*C. A.* 8, 3000) that in the operation of quenching the normal heat of the carbide, or other similar change, is retained in the rapidly cooled material and, when the heat change is suppressed in this way, very severe internal strains are produced in the material as is evidenced by an exceedingly large number of twin lamellae, is defended with particular reference to the criticisms of Rosenhain and the views of Humfrey and of Desch.

W. T. H.

The hardening of steel. J. O. ARNOLD. *Trans. Faraday Soc.* 10, 272-4(1915).—The theory is explained according to which the hardness of steel is assumed to be due merely to the inherent nature of certain chem. compds. such as hardenite, $21\text{Fe}_3\text{C}$. For the alloy steels, definite chem. compds. such as V-hardenite and W-hardenite are assumed.

W. T. H.

The hardening of metals. G. T. BEILBY. *Trans. Faraday Soc.* 10, 212-5(1915).—The amorphous theory, which accounts for the hardness of steel, is explained.

W. T. H.

The hardening of steel. R. HADFIELD, *et al.* *Trans. Faraday Soc.* 10, 275-93 (1915).—A discussion of the papers by Hadfield, Edwards, Arnold and Beilby (cf. preceding abstracts), Cohen (*C. A.* 8, 2295; 9, 1565), Humfrey (*C. A.* 9, 436), Desch (*C. A.* 9, 437), McCance (*C. A.* 8, 2998, 3773) and Howe (*C. A.* 9, 589). HADFIELD feels that the most important question to study is that relating to the combinations between Fe and C and has offered, through the Iron and Steel Institute, a prize of £200 for the best paper representing a general study of the carbides of Fe and in Fe alloys. J. E. STREAD points out the similarity between C and P in producing hardness, when in a solid soln. Twinning of itself is no indication of hardness. He also believes that more emphasis

should be laid upon the condition of the C. Ni steel with apparently the same structure under the microscope may be either hard or soft. A. McCANCE calls attention to the fact that hardness may be produced by pressure without permanent deformation and indicates the difficulties involved in explaining the magnetic properties of strained α and strained γ -Fe. Has it been shown that the amorphous state is actually harder than the crystalline state of the same substance at the same temp.? T. TURNER points out that the hardness of pure metals is proportional to the d. $\div$ at. wt., which indicates that hardness is due to molecular structure and anything that brings the mols. nearer together will produce hardness. He prefers to explain nearly all the changes that take place in various steels as due to soln. or pptn. of carbides and as the solid solns. vary in character and conc. different degrees of hardness result. W. H. HATFIELD shows that the amorphous theory does not entirely account for the hardness of steel. He believes that the hardness of quenched steel is due to the inherent hardness of the solid soln. which is trapped by the quenching. The so-called amorphous phase, whether in cold-worked metals or in quenched metals is "ultramicroscopic." W. ROSENHAIN points out that the twinning theory, as advanced by Carpenter and Edwards, rests on two separate assumptions which are opposed rather than supported by exptl. evidence. He regards the amorphous theory as probably offering the best working hypothesis at present and points out the similarity between it and the β -Fe theory and suggests that " β -Fe was buried too soon." T. G. Elliot, F. J. Brislee, T. K. Rose, G. T. Beilby and C. A. Edwards also took part in the discussion and H. L. Heathcote showed some simple devices for testing hardness. W. T. HALL.

Hardness tests made with a hand apparatus. F. TURPIN. *Rev. métal.* 12, 104-12 (1915).—A hand app. is described, consisting essentially of a steel sphere of 10 mm. diam. mounted at the end of a percussor within a hollow cylinder, so arranged that, on striking the percussor a sharp blow with a hammer, an imprint is made on the metal to be tested and also upon a ring of standard metal which is placed between the percussor and the steel sphere. The degree of hardness is detd. by measuring the diams. of the respective imprints and comparing these in an empirical formula with Brinell's scale of hardness. For ease of comparison, a slide rule has also been devised. The standard metal consists of a cylinder of steel 16 mm. diam. and 10 mm. high, well annealed so as to ensure as perfect homogeneity as possible. The slide rule is so constructed as to read off directly the (indentation) hardness number on the lower scale and the resistance in kg. per sq. mm. of section on the upper scale. An especial celluloid rule for measuring the diam. of the imprint is described. A discussion and résumé of the errors in measurement made with this instrument are given. The mean error of 250 tests controlled with Brinell's test was less than 6 kg. per sq. mm.

L. T. FAIRHALL.

The thermomagnetic study of steel. S. W. J. SMITH. *Imperial College Sci. Proc. Phys. Soc. London* 25, 77-81 (1913).—In the case of a simple ferromagnetic substance, magnetizing fields can generally be found in which the permeability variation with temp. is comparatively small except near the critical temp. In such fields there is a very clearly marked peak in the permeability-temp. curve. The peak is exhibited by cementite and in a particular steel (0.85 C) was sharply marked at 210°. It is suggested that the % C in steel could be detd. by some such thermomagnetic method.

PAUL D. FOOTE.

Thermomagnetic study of the eutectoid transition point of carbon steels. S. W. J. SMITH AND J. GUILD. *Trans. Roy. Soc. London (A)* 215, 177-204 (1915); cf. *Proc. Phys. Soc. London* 24, 62-9, 342-9 (1911) and preceding abstr.—The steels contd. from 0.15 to 1.53% C, about 0.2% Mn, 0.15% Si, and traces of S and P. Intensity of magnetization has been measured for all the specimens over the temp. range 670-800°.

In all of the steels a sudden loss of magnetization begins at the same temp. This accords with the view that the eutectoid patches detected by the microscope have always the same compn., and it suggests that this const. temp. is the true transition temp. between the eutectoid and the homogeneous soln. But when a very gradual heating was employed, a lower transition temp. was obtained in one specimen. The cooling curves show that the rapid return of magnetism in the eutectoid was no longer at a const. temp. except perhaps in the hyper-eutectoid steels. In the hypo-eutectoid steels the temp. of rapid return appears to become continuously lower as the % C falls. Methods are given for eliminating hysteresis in strong fields. A thermomagnetic method of estg. the % compn. of the eutectoid was outlined, but it could not be applied to steels rich in C. The effect of diffusion and the possible effect of pressure are discussed, and evidence of the relative unimportance of diffusion in low-C steels was presented. An hypothesis as to the mode of crystn. based on the assumption that the surface energy between the solid soln. and Fe is greater than that between it and the carbide has been worked out. The lag in pptn. of the eutectoid would be terminated by the crystn. of some of the Fe which it contains, but the sudden pptn. of Fe would increase temporarily to a very high value the concn. of the carbide in soln. in its immediate neighborhood and the crystn. of one constituent would induce the appearance of the other.

E. B. MILLARD.

Measurement of the temperature coefficient of Young's modulus for metallic wires, with special application to nickel. E. P. HARRISON. *Calcutta. Proc. Phys. Soc. London* 27, 8-38(1914).—Young's modulus for Ni decreases slowly with increasing temp., the relation being parabolic up to 300°. An anomalous change in the temp. coeff. of the modulus occurs at the same temp. as the magnetic, thermoelec., resistance and expansion crit. points, *i. e.* 365 to 425°. When the temp. is const. and elastic after-effects are absent or corrected for, load-elongation graphs are linear, showing (a) that no appreciable irreversible effects are produced on loading and then unloading, (b) that the elastic temp. coeff. is the same for all loads used. The value $\alpha d\alpha/dT$, where α is the coeff. of expansion under tension T , is deduced from the thermal coeff. of Young's modulus.

PAUL D. FOOTE.

The elastic strength of metals. FRANK C. THOMPSON. *Sheffield Univ. Trans. Faraday Soc.* May 11, 1915 (13 pp.) (*advance proof*).—When 2 similar plates are sepd. by a film of liquid which wets them, the force which holds them together is $2AT \div d$ dynes where A is the area of the plate, T is the surface tension of the liquid, and d is the thickness of the film. Ordinarily the pressure is derived from that of the atmosphere but in the case of the amorphous cement surrounding the crystals of a metal, the pressure arises from the vectorial forces of crystallization. Such attractions may attain very considerable magnitudes and the strength of the junctions, and therefore of a metal, may be regarded as being due to these attractions between all adjacent faces in the mass. Since the attraction between the crystals is inversely proportional to the distance between them, the very thinness of the films is the source of their greatest strength. Acting on this assumption, the effect of strain on metals is explained and the theory is applied not only qualitatively but quantitatively in an exptl. study of the elastic limit, max. stress and elongation of Cu, Zn, Sb, Ni, Pb, Sn, Ag, annealed Fe, normalized Fe and Fe which has been quenched and tempered. The effect of temp. on the mechanical properties of metals and the elec. cond. is also interpreted in the light of the amorphous cement theory. As regards the actual thickness of the film of amorphous cement, it is probably nearly within the range of microscopic vision, *i. e.*, not far from 10^{-8} cm.

W. T. HALL.

Observations relative to the annealing of metals. G. MÉKER. *Rev. metal.* 12, 101-3(1915).—Expts. show that in order to obtain properly annealed pieces of steel

or other metals having a sound surface, it is best to grease the pieces with a lubricating substance containing only hydrocarbons or natural fats without mineral matter. Lubricants containing fixed salts impart a rough surface to the metal in the process of annealing.

L. T. FAIRHALL.

Cerium-magnesium alloys. RUDOLF VOGEL. Göttingen. *Z. anorg. Chem.* 91, 277-98(1915).—Alloys of Ce and Mg were prepd. by heating the 2 metals in C tubes; the considerable difficulty encountered in obtaining homogeneous melts because of the great difference in d. of the 2 components was overcome by use of an iron stirrer, and by repeated fusions. The following compds. are formed: Ce_2Mg , m. 632° , decomp. on cooling to 497° into Ce and CeMg ; CeMg , m. 738° , hardness almost 5, strongly pyrophoric, burns violently on heating, stable in air, less rapidly acted on by dil. acids than Ce; CeMg_2 , m. 780° , hardness 4, brittle, not pyrophoric, more stable than CeMg ; CeMg_3 , decomp. at 622° and 91% Mg, forming CeMg_2 + melt, hardness 3, brittle, breaks up on standing some weeks, probably due to transition into a polymorphous form, more stable than CeMg_3 . Ce m. 840° ; the Ce- Ce_2Mg eutectic and the Ce_2Mg - CeMg eutectic are both at about 632° and near Ce_2Mg in compn. CeMg and CeMg_3 are miscible in the solid state between the limits 50-62% Mg, with a temp. minimum in the m. p. curve at 54% Mg and 700° . The CeMg_2 -Mg eutectic is at 585° and 93% Mg; Mg m. 661° .

GEORGE W. MORREY.

The behavior of vanadium toward silicon, nickel, copper and silver, and the behavior of boron toward nickel. HANS GIEBELHAUSEN. Göttingen. *Z. anorg. Chem.* 91, 251-62(1915).—Some fusion curves in binary systems have been detd. and supplemented by microscopical exam. In the system V-Si, which was followed from 0 to 60% V, the compd. VSi_2 , m. 1655° , is formed; the Si- VSi_2 eutectic is at 1411° and 5 wt. % V. No indication of miscibility in the solid state was observed; the alloys are brittle, and the compd. VSi_2 scratches Si. In the region 0-36% V, Ni and V form solid solns. with a point of minimum temp. at 1326° and 21% V. The alloys increase in hardness up to 12% V, after which the hardness remains sensibly const.; addition of V also lowers the magnetic critical temp. of the Ni. In the systems Cu-V and Ag-V two liquid layers are formed, each of which consists practically of a pure component. In the system Ni-B the compds. obtained were Ni_2B , m. 1225° , Ni_3B_2 , m. about 1160° (read from curve), which exists in 2 forms with inversion temp. at 1050° , and Ni_2B_3 . The Ni- Ni_2B eutectic is at 4 wt. % B, 1125° ; the Ni_2B -NiB eutectic is at about 1080° 12.5 wt. % B (read from curve). Cooling curves of melts containing Ni_2B_3 as primary phase show several breaks, probably due to the above inversion taking place sluggishly and incompletely. The fusion curve rises rapidly on addition of B to the compd. NiB, and was only followed to a little over 18% B and about 1240° ; in this region mixed crystals of NiB and Ni_2B_3 separate; they unmix at 965° . The thermal data for this system are not given, so exact information is not available. B is not dissolved appreciably by Cu, Ag, Ti, Bi, Pb or Sn at 1500 - 1600° , nor does boiling Zn affect it; molten Al dissolves noticeable amts. of B, and molten Mn and Cr at least 10-20%. CaF_2 and BaF_2 dissolve B, which gives, on cooling, well formed crystals; B and CdF_2 at 1000° to 1200° react energetically with evolution of BF_3 and Cd. G. W. MORREY.

Tests on the combined bending and torsional strength of cast iron. TSURUZO MATSUMURA and GENJIRO HAMABE. *Mem. Coll. Engineering, Kyoto Imp. Univ.* [2] 1, 47-53(1915).

W. T. H.

The influence of wire drawing on the properties of mild steel wire. HERMANN ALTPETER. *Stahl u. Eisen* 35, 362-73(1915).—The structure of the cross sections of wire in the various stages of drawing down from 13.85 mm. confirmed the researches of Heyn on the appearance of the ferrite grains. The solubility of the unannealed wire in 1% H_2SO_4 was found to increase with the reduction in cross section. Tests

with the Shore scleroscope showed that the hardness of a cross section increased from the edge to the center. Logarithmic plots of the breaking loads of hard-drawn and annealed wired, resp., showed that the points fell on parallel lines. This was also true of the results obtained in breaking the wire by bending. These curves have practical value in that having detd. one value the other figures for a given wire may be predicted.

CARLE R. HAYWARD.

Influence of nickel on the mechanical properties of copper. W. STAHL. *Metal* u. *Ers* 3, 179(1915).—Ni has been shown to be sol. in Cu in all proportions. Cu with about 10% Ni has high tensile strength accompanied by high ductility and reduction of area. It withstands heat well.

CARLE R. HAYWARD.

Prevention of rapid corrosion of galvanizing pans. C. DIEGEL. *Z. Ver. deut. Ing.* 59, 362-3(1915).—A series of expts. was conducted to det. the cause of rapid corrosion of galvanizing pans. The results indicate that irregular structure increases the solubility of Fe in Zn. High C content does not increase solubility; in superheated baths it decreases it appreciably. Differences in P content from 0.025 to 0.09% do not noticeably affect the solubility at the usual temp. of the Zn bath; in superheated baths a high P content acts unfavorably. Increasing the Si content appreciably increases the solubility of the Fe. The temp. of the bath exerts a greater influence on the solubility than all the above causes. The Fe dissolved in a unit time at 500° may be 9 times and at 530° 30 times the solubility at temps. below 490°. If the Zn bath is retained at a temp. of 500° and more, a quick destruction of the pan must result. Rapid corrosion is in general due to the use of baths at too high a temp. or to repeated heating and cooling.

Methods for determining the galvanizing process and the thickness of the zinc coating of galvanized iron objects. O. BAUER. *Mitt. kgl. Materialprüfungsamt.* 32, 448-74(1914); through *Chem. Zentr.* 1915, I, 811-2.—The galvanizing processes and the metallographic characteristics of the different products are briefly discussed. B. gives a method for differentiating hot or fire galvanizing and electrolytic galvanizing based on the difficult dissolving of Fe in dil. H_2SO_4 containing As_2O_3 , while Zn, as well as fire galvanized objects, owing to the intermediate Fe-Zn alloy layer, readily dissolve with vigorous evolution of H. Such a layer is not present in electrolytic galvanized Fe. Two % H_2SO_4 containing 2 g. of As_2O_3 per l. is used for the test. On treating the galvanized object with $As_2O_3-H_2SO_4$ the Zn is dissolved in a few seconds (the end of reaction being sharply indicated by cessation of H evolution), and the object immediately removed from the soln. If the soln. contains Fe, it is from the Zn coating or the Fe-alloy layer which forms in fire galvanizing; at the same time any Pb present in the Zn used adheres partly to the test piece and seps. partly as flocks in the soln. in the case of fired objects. With electrolytic objects the soln. is clear, free from Fe and no Pb seps. out. The amt. of the Zn coating may be detd. by loss in wt. Since the soln. of the Zn in the $As_2O_3-H_2SO_4$ can be masked by the reduced As, a soln. of NH_4NO_3 (200 g. per l.) is recommended for use instead; in this case some Pb remains as a spongy residue adhering loosely to the Fe or in flocks in the soln.

F. W. SMITHER.

Protection of metal structures. FREDERIC H. FAY. *Proc. Eng. Soc. Western Penn.* 31, 115-222(1915).—Paper and symposium. F. limits the subject to the corrosion of the metal work of bridges, and enumerates as the principal causes, (1) exposure to locomotive gases, (2) exposure to sea water, (3) exposure to surface water leaking through bridge floors, and (4) over-stress of the metal by which corrosion has been hastened. He discusses the merits of paints, wooden ceilings, sheet lead coverings, asphalt coatings, and concrete as means of protection. A complete bibliography on the subject of corrosion of metals is included.

According to the principal process, the materials used to prevent the action of rust, besides graphite, were Fe_2O_3 and MnO_3 , as well as other substances yielding O. Instead of Fe oxides, or in addition thereto, the oxides of Cu, Ni and Co may be used. These oxides are converted, with acids or alkalis, into a paste in order that they may be applied. Upon burning, the graphite and the other carboniferous materials act first upon the oxides of Cu, Ni, and Co to reduce them, whereupon the resulting metals penetrate deeply into the molten layer of Fe formed at the same time. By the oxidizing action of the MnO_3 the metals formed at first are reconverted into oxides and, either by themselves or in conjunction with Fe_2O_3 , and the MnO resulting from the reduction of the MnO_3 , constitute a protective coating.

Ger., 282,131, Oct. 8, 1913. F. LANGGUTH. Separating the sulfur compounds of lead and zinc from other ores. By the known flotation process, only the sepn. of the ores from the gang can be effected, not the sepn. of the several kinds of ore. This process is dependent upon the observation that the various ores, especially after the addition of oil, behave differently towards aq. ZnCl_2 soln. acidified with HCl. The sulfides of Zn and Pb do not float in this soln., while the other ores have the same property of flotation as in solns. free from ZnCl_2 . Therefore, after sepn. in the known manner from the gang, the ores are treated with ZnCl_2 soln. containing HCl, whereupon the S compds. of Pb and Zn settle, while the other ores rise and are thus sepd. The process can be repeated in treating the particles which have floated off in order to sep. the Zn and Pb particles carried over mechanically. Preferably, a soln. of 2% or more of ZnCl_2 is used. Instead of the HCl, other acids which do not decompose the ZnCl_2 may be employed. Impure ZnCl_2 solns., containing NaCl, CaCl_2 , FeCl_3 , etc., may be employed also. Cf. U. S., 1,144,481 (*supra*).

Ger., 282,137, June 18, 1913. AKTIEBOLAGET GRONDÄLS PATENTER. Agglomerating fine ore (Fe ore) by mixing it with somewhat more coal than corresponds to the equation $25\text{Fe}_2\text{O}_3 + 72\text{C} = 75\text{Fe} + 44\text{CO} + 28\text{CO}_2$, i. e., with somewhat more than 0.205 part by wt. of C to 1 part of Fe. The moistened ore-coal mixt. is charged into a converter upon the floor of which rests a layer of coal. After the charging, the material is packed solid and perforated so that canals, regularly spaced, lead to the layer of coal. After the combustion of the coal has been started, a slow current of air is conducted through the layer of coal for the purpose of producing gas rich in CO which passes through the canals and reduces the ore mixt. in the walls of the canal to FeO, which slags readily with the SiO_2 in the ore mixt. and coats the walls of the canals with a layer of slag which prevents the penetration of the CO_2 in the hot gas into the ore mixed with coal. The current of air is then increased and the temp. is thereby increased. In the sealed ore mixt. an energetic reduction takes place under these conditions. In order to facilitate the slag formation on the surface of the perforations, a readily fusible dressing may be applied.

Ger., 282,228, May 29, 1913. E. DREVES. Sealing the upper from the lower portions of a tunnel furnace for heating and chem. treating ores and the like.

Ger., 282,328, Dec. 4, 1913. A. LANG. Mfg. rust-proof articles from aluminium and heavy metals, by applying to the exposed parts a layer of oxide or sulfide which is

not attacked by dil. acids or alkalis (PbS , Cr_2S_3 , etc.). *E. g.*, if a vessel is made of Al and Ni, the Al is oxidized in the known manner and the Ni portion is converted superficially into NiS. By warming these layers become denser, and may be manipulated further. The oxides and sulfides of other metals can be used also.

Ger., 282,509, July 31, 1912. GES. ZUR AUSBEUTUNG VON CHEM. UND TECH. ERFINDUNGEN v. J. T. WESTERMANN. A lining for crucibles, furnaces, and the like, for m. metals, consists of a mixt. of graphite, Al Mg hydrosilicate, and Al powder, with an addition of pure asphalt dissolved in turpentine, petroleum, or the like, of wood tar, H_2O , or other liquids. The dressing can be applied repeatedly, as required. The Al powder is added as a strong reducing agent. The addition of asphalt soln. and wood tar serves to keep out moisture. About 45% graphite, 45% Al Mg hydrosilicate, and 10% Al powder, with a 10–20% asphalt-turpentine soln. or asphalt-petroleum soln., or pure H_2O as binder.

Ger., 282,600, Aug. 30, 1912. J. P. DOANIDES. Mfg. articles from lead slag.

C. A. ROUILLER.

Synthesis of benzo- γ -pyrones and flavones. I. SERGE JACOBSON AND BRO-JENDRANATH GHOSH. *J. Chem. Soc.* 107, 424–34 (1915).—By condensing phenols in the cold with $\text{MeC}(\text{OH})\text{:C}(\text{CH}_3\text{Ph})\text{CO}_2\text{Et}$, in the presence of sufficient H_2SO_4 , J. and G. prepd. benzo- γ -pyrones, all of which developed marked bluish or greenish fluorescence in concd. H_2SO_4 . The crude pyrones were usually contaminated with methylindenecarboxylic acid, which was removed by dissolving the mixt. in dil. NaOH and reprecip. the pyrone by means of CO_2 . The following γ -pyrones and their derivs. have been synthesized: 7-Hydroxy-3-benzyl-2-methylbenzo- γ -pyrone (A),
 $\text{HOC}_6\text{H}_4\text{.O.CMe:C}(\text{CH}_3\text{Ph}).\text{CO}_2\text{.}^1\text{H}_2\text{O}$ (derived from resorcinol), yellowish needles

from EtOH, m. 186° ; acetate (B), silky needles, m. 168° ; benzoate, long needles, m. 150° ; methyl ether, needles from AcOH, m. 119° ; ethyl ether, thin needles from EtOH, m. 145° ; both ethers develop fluorescence in concd. H_2SO_4 . If resorcinol and $\text{MeC}(\text{OH})\text{:C}(\text{CH}_3\text{Ph})\text{CO}_2\text{Et}$ are condensed in the presence of comparatively small amts. of H_2SO_4 , 7-hydroxy-3-m-hydroxyphenoxy-3-benzyl-2-methylbenzo- γ -pyrone, yellow prisms, m. 224° , is formed instead of (A) but yields (B) on acetylation. When decompd. with alkali, (A) yielded $\text{Ac}(\text{CH}_2)_2\text{Ph}$ (identified by means of its semicarbazone, m. 142°) and β -resorcylic acid, m. $202\text{--}3^\circ$. The thio derivative of (A), $\text{HSC}_6\text{H}_4\text{.O.CMe:C}(\text{CH}_3\text{Ph}).\text{CS}$,

brick-red prisms, m. 198° (decompn.), was synthesized by fusing (A) with P_2S_5 . 3-Benzyl-2,7-dimethylbenzo- γ -pyrone (derived from *m*-cresol), needles, m. 117° , probably identical with the "coumarin" described by Fries and Klostermann (*Ann.* 362, 27). On attempting to prep. a compd. m. 87° (described by Fries) from *m*-cresol and $\text{MeC}(\text{OH})\text{:C}(\text{Et})\text{CO}_2\text{Et}$, J. and G. obtained an additive compound, $\text{C}_{20}\text{H}_{20}\text{O}_3$, m. 130° . 3-Benzyl-2-methyl-1,4, α -naphthapyrone (from α -naphthol), yellow needles from EtOH, m. 187° , is converted, on hydrolysis with alkali, into $\text{Ac}(\text{CH}_2)_2\text{Ph}$ and 1-naphthol-2-carboxylic acid (cf. Schmidt and Burkard, *Ber.* 20, 2699), whose acetate m. 143° . 7,8-Dihydroxy-3-benzyl-2-methylbenzo- γ -pyrone (from pyrogallol), m. 185° ; acetate, prisms, m. 172° ; benzoate, needles, m. 184° . 7-Hydroxy-3-benzyl-2,5-dimethylbenzo- γ -pyrone, needles from AcOH, m. $177\text{--}8^\circ$; acetate, needles, m. 169° ; benzoate, m. $119\text{--}20^\circ$. 5,7-Dihydroxy-3-benzyl-2-methylbenzo- γ -pyrone, needles from AcOH, m. $218\text{--}9^\circ$; acetate, silky needles, m. 154° .

LOUIS E. WISE.

Conversion of racemic acid into a mixture of racemic and *d*-tartaric acids by means of *l*-malic acid. ALEXANDER MCKENZIE. Univ. Coll. Dundee. *J. Chem. Soc.* 107, 440-3(1915).—In an attempt to resolve a *dl*-acid by combining it with a *different* optically active acid, McK. neutralized 1 mol. of pure *dl*-tartaric acid with aq. KOH and added 1 mol. *l*-malic acid. The cryst. product which sepd. was *slightly but distinctly d-rotatory* and consisted of a mixt. of *dl*-KH tartrate and *d*-KH tartrate. In control expts. in which *dl*-KH tartrate was crystd. from H₂O, without addition of *l*-malic acid, the $[\alpha]_D$ of the product was invariably $\approx 0^\circ$. Van't Hoff's idea regarding the possibility of activating an inactive compd. by crystg. it from an active solvent has apparently been experimentally realized.

LOUIS E. WISE.

Configuration of the stereoisomeric diphenylsuccinic acids. HENRY WREN AND CHARLES J. STILL. Municipal Tech. Inst., Belfast. *J. Chem. Soc.* 107, 444-51(1915).— α -Diphenylsuccinic acid (A), m. 183° , and, after resolidification, rem. $220-1^\circ$ (cf. Franchimont, *Ber.* 5, 1050; Reimer, *Ibid* 14, 1802, *et al.*), was conveniently prepd. by the following method: Powdered EtONa (containing 8 g. Na) was suspended in 49.2 g. PhCH₂CO₂Et in 100 cc. Et₂O and to the mixt. were gradually added 38.1 g. I in 200 cc. Et₂O. After standing at room temp. for several hrs., Na₂S₂O₃ was added to the soln. to remove the excess of I, the flocculent Et β -diphenylsuccinate removed by filtration, the filtrate extd. with Et₂O, and the ext. dried, evapd. and finally heated under reduced pressure to remove unchanged PhCH₂CO₂Et. The residue was hydrolyzed with aq. alc. KOH, the EtOH removed by evapn. and the soln. filtered. The Ba salt of (A), pptd. from the filtrate, yielded 18.8 g. (A) upon acidification. By the repeated fractional crystn. of its brucine salt, (A) was resolved into its 2 optically active components: the *d*-isomer, microneedles, m. to a pasty liquid $179-80^\circ$, resolidifying and rem. $212-4^\circ$, $[\alpha]_D^{15}$ in acetone 397.3° , $[\alpha]_D^{15}$ in EtOH 369.5° , $[\alpha]_D^{15}$ in MeOH 369.2° , in AcOEt 403° ; *l*-isomer, m. $176-7^\circ$, resolidifying and rem. $211.5-14^\circ$, $[\alpha]_D^{15}$ -368.9° . β -Diphenylsuccinic acid (C) m. $229-30^\circ$, $[\alpha]_D \approx 0^\circ$ (cf. Chalanay and Knoevenagel, *Ber.* 25, 285; Reimer, *et al.*), prepd. from its Et ester (B) by hydrolysis with aq. HCl in sealed tubes or from diphenylsuccinonitrile by hydrolysis, could not be resolved into its optically active components. (A) is therefore the *dl*-mixt. and (C) the *meso* acid.

LOUIS E. WISE.

Formation of dialkyloxyanilines in reduction processes. EUSTACE E. TURNER. Goldsmith's Coll., London. *J. Chem. Soc.* 107, 469-74(1915).—2-Nitroresorcinol di-Et ether, pale green needles, m. 106.5° (cf. de Pay, *Ber.* 39, 2723 (1906), footnote), formed by heating a mixt. of 10 g. 2-nitroresorcinol and 20 g. EtBr in EtOH with 7.2 g. KOH in 24 cc. H₂O, in a closed vessel for 6 hrs., was reduced by Sn and HCl to 2-aminoresorcinol diethyl ether (A), needles from petroleum, m. 57° . The hydrochloride and chloroplatinate, reddish yellow needles, were prepd. from (A). The diazo deriv. of (A) coupled with β -naphthol gives rise to 2,6-diethoxybenzeneazo- β -naphthol, red plates with a green reflex from glacial AcOH, m. 104° . Evidently the so-called "2-aminoresorcinol di-Et ether," m. 124° , described by Pukall (*Ber.* 20, 1136) is another compd., probably [4,3,5-H₃N(EtO)₂C₆H₃] (its formation being due to a benzidine rearrangement). Kauffmann (*C. A.* 2, 272) in reducing 2-nitroresorcinol di-Me ether always obtained a mixt. of the corresponding NH₂ deriv. (B) and a Cl-containing product (C). While the purification of (B) presented no difficulties, (C) which was present always in small amt., tended to form very stable mixed crystals with (B), which m. 36° and contained 54.8% C and 5.97% H. The sepn. of (B) and (C) was effected by distg. the mixt. under 15 mm., (B) distg. completely at 140° and leaving pure (C) as residue. (C) was shown to be a chloro-2-aminoresorcinol dimethyl ether, needles, m. 50° , whose hydrochloride may be readily diazotized and coupled with β -naphthol, forming a hydroxyazo compd. The chloroplatinate of (C) forms rosettes of needles.

The hydrochloride of (B) forms long needles; the chloroplatinate nearly colorless needles, becoming orange-yellow on exposure to light. When the diazo deriv. of (B) was treated with a large quantity of 50% H_2SO_4 and K_2SO_4 and distd. in a current of superheated steam, a product (D), probably pyrogallol di-Me ether, was obtained. On treatment with CrO_3 in glacial AcOH , (D) yielded cerulignone, which gave the "corn flower" blue coloration with concd. H_2SO_4 .

LOUIS E. WISE.

Action of aldehydes on the Grignard reagent. II. JOSEPH MARSHALL. Leeds. *J. Chem. Soc.* 107, 509-23 (1915); cf. *C. A.* 8, 1957.—A new explanation of Sabatier and Murat's results (*C. A.* 8, 1088) is offered. Instead of obtaining Ph_2CHOH in quantity by the action of BzH and PhMgBr , S. and M. obtained largely $(\text{Ph}_2\text{CH})_2$, together with smaller amts. of BzPh and Ph_2CH_2 . M. has shown that in the formation of PhMgBr from PhBr , a certain amt. of Mg always remains undissolved, hence when an "equimol." amt. of BzH is added to the Grignard reagent, there is in reality an excess of BzH present, which may react further with the addition product $\text{Ph}_2\text{CHOMgBr}$, to form a compd. which on hydrolysis yields some BzPh . H , which is also liberated during the reaction owing to the soln. of the excess of Mg , reduces $\text{Ph}_2\text{CHOMgBr}$ or Ph_2CHOH to $(\text{Ph}_2\text{CH})_2$ or to Ph_2CH_2 . When the excess of Mg was removed from the Grignard reagent and the true equimol. amt. of BzH was used, 55% of Ph_2CHOH was obtained. PhMgBr , containing an excess of Mg , when acted upon by BzPh , did not lead to the formation of $(\text{Ph}_2\text{C})_2$ but yielded solely Ph_2COH (in 60% yield). When < 1 mol. BzH acted upon $p\text{-MeC}_6\text{H}_4\text{MgI}$ (A), the chief product was $p\text{-MeC}_6\text{H}_4\text{CPhOH}$. If 2 mols. BzH were used in the reaction, PhCH_2OH and $p\text{-MeC}_6\text{H}_4\text{Bz}$ were formed. p -Ditolyl was formed in considerable quantity in both reactions. The reaction between BzH and MeMgI (previously reported) was repeated and the reaction products more carefully examd. 2 fractions were obtained: (a) b_{18} below 150° , yielding largely PhAc , and (b), b_{18} $200\text{--}25^\circ$, yielding PhCH:CHBz (obtained in the form of the hydrochloride, m. 112°) and Bz_2CH_2 , m. $80\text{--}1^\circ$ (readily converted into 1,3-diphenylisooxazole, m. 141°). A reaction mixt. containing 1.5 mols. BzH and 1 mol. EtMgBr in Et_2O , after being gently heated for 24 hrs., sepd. into 2 layers. The upper Et_2O layer yielded only small amts. of BzH ; the lower viscous layer was sepd. into 2 fractions: (c), b_{18} $90\text{--}155^\circ$, and (d), $b_{18}(?)$ $160\text{--}240^\circ$. (c) yielded largely PhCH_2OH and BzH and a mixt. of PhCH_2EtOH and BzEt . (d) yielded solely Bz_2CHMe , m. $84\text{--}5^\circ$ (cf. Abell, *ibid* 79, 929), which was readily converted into N:PhC.CMe:CPh.NH , m. 233° ,

by the action of N_2H_4 ; into 1,3,5-triphenyl-4-methylpyrazole, silky needles, m. 125° , by the action of PhNHNH_2 ; into 3,5-diphenyl-4-methylisooxazole, plates, m. 127° , by the action HONH_2HCl ; and into bromodibenzoylthane, prisms, m. 65° , by the action of Br in CCl_4 . 1.5 mols. BzH acting upon 1 mol. of PrMgI yielded principally Bz_2CHEt , m. 87° (cf. Auger, *Ann. chim. phys.* [6] 22, 351), which could be converted into bromodibenzoylpropane, Bz_2CEtBr , hexagons, m. 52° ; 1,3,5-triphenyl-4-ethylpyrazole, needles, m. $84\text{--}5^\circ$; and 1,3-diphenyl-2-ethylisooxazole, needles, m. 93° . A similar reaction with iso- PrMgI yielded a mixt. of iso- PrPhCHOH , iso- PrBz and an unidentified substance, m. 110° . BzH reacting with PhCH_2MgBr (which invariably contains a large excess of uncombined Mg and which must, therefore, be treated with $<$ an equimol. amt. of BzH) gave rise to a mixt. from which only the component of highest b. p., dibenzoylphenylmethane, needles, m. 149° , was isolated. The following derivs. of this compd. were prepd.: 1,3,4,5-tetraphenylpyrazole, needles, m. 167° ; bromodibenzoylphenylmethane, prisms, m. 147° ; dibenzoylphenylmethane oxime, needles, m. 153° , which when heated above its m. p. is converted into 3,4,5-triphenylisooxazole, needles, m. 212° . BzH acting upon Me_2CHMgI yielded chiefly PhCH:CHAc , identified by its conversion into the oxime, m. 116° , and into the phenylhydrazone, m. 156° ,

which readily forms 1,5-diphenyl-3-methylpyrazoline, needles, m. 114° , to whose pure solns. (which are not fluorescent) may be imparted a vivid magenta color upon the addition of traces of NaNO_2 . 4 mols. of AcH reacting with PhCHEtMgBr yielded largely BzMe , some impure MeCH:CHBz(?) , and BzCH_2Ac , m. $59-60^{\circ}$, characterized by the formation of its deriv., phenylmethyloxazole, m. $68-9^{\circ}$. AcH reacting with iso-PrMgI gave rise to AcMe , iso-PrOH and a small amt. of impure ethylideneacetone, yielding 1-phenyl-3,5-dimethylpyrazoline when treated with PhNHNH_2 . In an expt. in which BzH was allowed to react with $\text{Ph}_2\text{CMeMgBr}$, Ph_2CMeOH and BzCH_2 were the only products formed. BzMe reacting with Ph_2CHMgBr yielded some compd., which on hydrolysis regenerated nearly all of the BzMe together with some benzhydryl ether, m. 110° . AcOEt and PhCHMeMgI gave rise to PhMeCH-OAc , b₁₆, $105-8^{\circ}$. Similarly Ph_2CHMgBr and AcOEt yield Ph_2CHOAc . Numerous equations are given to explain the mechanism of some of the above reactions.

LOUIS E. WISE.

Dihydric alcohols obtained by the reduction of substituted dihydroresorcinols. ARTHUR W. CROSSLEY AND NORA RENOUF. Kings Coll., London. *J. Chem. Soc.* 107, 602-10(1915).—By reducing dimethyldihydroresorcinol in EtOH with Na , C . and R . obtained a mixt. of 1,1-dimethylcyclohexane-3,5-diol (*A*) (cf. Zelinskii and Uspenskii, *C. A.* 7, 3600), nacreous scales, m. 147° (66-8% yield) and 1,1-dimethylcyclohexan-3-ol, b₁₆ $102-3^{\circ}$ (7-10%); *o*-nitrobenzoate, flat needles, m. 62° . Dibenzoate of (*A*) needles, m. $135-6^{\circ}$. By heating slightly more than 1 mol. of $\text{AcCH}_3\text{CO}_2\text{Et}$ with 1 mol. EtONa in EtOH and adding 1 mol. Et crotonate to the mixt., heating on a H_2O bath for 7 hrs., dissolving the residue in H_2O , removing the EtOH by evapn., adding 2 mols. KOH , dilg. the soln. so as to contain 10% alkali, heating in an open flask, acidifying and finally boiling until the evolution of CO_2 had ceased (to insure decompn. of the corresponding resorcylic acid), C . and R . obtained a 67% yield of methylidihydroresorcinol, m. (after crystn. from AcOEt) 128° , which upon reduction with Na in EtOH yielded a mixt. of crude 1-methylcyclohexane-3,5-diol (*B*) and 1-methylcyclohexan-3-ol (the latter being sepd. by steam distn.); *o*-nitrobenzoate, rhombs, m. 54° . Pure (*B*) obtained in 43% yield by repeated Et_2O extns. of the crude product, crystd. from the Et_2O exts. in rhombs, m. $74-5^{\circ}$, and from AcOEt in needles. Its *dibenzoate*, hexagonal plates, m. 81° . The Et_2O mother liquor from (*B*) yielded a very small amt. of an isomeric diol(?), nacreous flattened needles, m. 143.5° . 1,1,2-Trimethylcyclohexane-3,5-diol, flat needles, m. 150° ; *dibenzoate*, needles, m. 97° , was obtained in 70% yield by the reduction of trimethyldihydroresorcinol. Trimethylhexan-3-ol, a by-product of the above reaction, was identified by means of its *o*-nitrobenzoate, m. 114° (cf. *C. A.* 5, 3559). By a similar reaction, 40% of the theoretical yield of 1-isopropylcyclohexane-3,5-diol, flat needles (*C*), m. 124° , was obtained, after repeated Et_2O extn. of the crude product. The volatile by-product, 1-isopropylcyclohexan-3-ol (*o*-nitrobenzoate, m. $48-9^{\circ}$) was sepd. from (*C*) by distn. with steam. *Dibenzoate* of (*C*), needles, m. 84° . By the usual reduction of phenyldihydroresorcinol (cf. Vorländer, *Ber.* 27, 2054), a mixt. of 1-phenylcyclohexane-3,5-diol, leaflets from AcOEt , m. 160° (*D*) (cf. Knoevenagel, *Ann.* 289, 167) and 1-phenylcyclohexan-3-ol, needles from light petroleum, m. 81° , sepd. from (*D*) by steam distn. The Et_2O mother liquors from which (*D*) had been crystd. in the process of purification on evapn. yielded an isomeric (*cis?*)-1-phenylcyclohexane-3,5-diol (*E*), scaly needles from AcOEt or H_2O , m. 134° , whose *dibenzoate*, silky needles from EtOH , m. 117° , regenerated (*E*) quant. on hydrolysis with alc. KOH . (*D*) yields a *dibenzoate*, needles from abs. EtOH , m. poorly $110-27^{\circ}$, and containing 0.5 mol. of EtOH which could not be removed by heating to 100° or by keeping *in vacuo*. The *dibenzoate* regenerated (*D*) quant. when sapond. with alc. KOH .

LOUIS E. WISE.

Alkylated *p*-phenylenediamines and derivatives. Quinoneimide-ammonium compounds. RAPHAEL MELDOLA AND WILLIAM F. HOLLELY. City and Guilds Tech. Coll., Finsbury. *J. Chem. Soc.* 107, 610-22 (1915).—The main object of the research was to prep. quinoneimide-ammonium compds. with special reference to derivs. of the type $p\text{-HN:C}_6\text{H}_4\text{:Nabc}$ (in which *a*, *b* and *c* are different radicals) which should be resolvable into optically active isomers. M. and H.'s results are as yet inconclusive. In the present paper they describe the prepn. and properties of the parent alkylated *p*-phenylenediamines and their derivs. The synthesis of *p*-methylethylaminoacetanilide (A), $\text{EtMeNC}_6\text{H}_4\text{NHAc}$, silky needles, m. 92° , may be outlined as follows:

$\text{PhNMeEt.HCl} \xrightarrow{\text{NaNO}_2} p\text{-NO deriv.} \xrightarrow{\text{Sn + HCl}} p\text{-NH}_2 \text{ deriv.} \xrightarrow{\text{Ac}_2\text{O}} \text{(A)}$. At ordinary temp. but more rapidly on heating, (A) adds alkyl iodides (excepting iso-PrI) to form quaternary NH_4 iodides, cryst. H_2O -sol. products which dissociate readily on attempted recrystn. from H_2O or EtOH, and which on treatment with Ag_2O form alk. syrups which rapidly absorb CO_2 from the air, giving rise to uncrystallizable carbonates. *Methylethylpropyl-4-acetaminophenylammonium iodide* (B) and the corresponding *allyl iodide* were especially studied. Acid hydrolyzing agents readily remove the Ac group with the formation of corresponding quaternary NH_4 salts, but attempts to form quinoneimide- NH_4 compds. and their NO_2 derivs. were unsuccessful. The hydrolysis of (B) with HBr lead to the formation of a *dibromide*, $4\text{-HBr.H}_2\text{NC}_6\text{H}_4\text{-NBrMeEtPr}$, colorless tablets. (A) in cold glacial AcOH, when treated with fuming HNO_3 yielded *3,5-dinitro-1-acetaminophenyl-4-methylnitrosoamine* (C), $(\text{ONMe})(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{NHAc}$, colorless prisms, tablets, or scales, m. $152\text{--}3^\circ$. When boiled with abs. PhOH (C) loses its NO group and passes into *3,5-dinitro-4-methylamino-1-acetanilide* (D), $(\text{O}_2\text{N})_2(\text{MeNH})\text{C}_6\text{H}_3\text{NHAc}$, or more probably possessing the "inner salt"

structure $\text{AcHN} \begin{array}{c} \text{NO}_2 \\ \diagup \quad \diagdown \\ \text{C}_6\text{H}_3 \\ \diagdown \quad \diagup \\ \text{:N-O} \\ \vdots \\ \text{O} \end{array} \text{:NMe}$, scarlet needles, m. $196\text{--}7^\circ$, which in turn passes

into *3,5-dinitromethyl-*p*-phenylenediamine* (*3,5-dinitro-4-methylaminoaniline*), $(\text{O}_2\text{N})_2(\text{MeHN})\text{C}_6\text{H}_3\text{NH}_2$ (or the corresponding "inner salt" structure), dark purple needles with green reflex, m. $186\text{--}7^\circ$, whose diazo deriv. is readily decompd. with EtOH with the formation of *2,6-(O}_2\text{N})_2\text{C}_6\text{H}_3\text{NHMe}* (E), orange needles, m. $106\text{--}7^\circ$ (cf. Bamberger, *Ber.* 30, 1257). (E) was also obtained directly from (C), by heating the latter with alc. HCl. The *nitroso derivative* of (E), needles, m. $115\text{--}6^\circ$. Fuming HNO_3 acted further upon (C) with the formation of a corresponding *nitroamine*, $4,3,5\text{-(O}_2\text{NMeN)-}(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{NHAc}$, needles, m. $183\text{--}4^\circ$, passing into (D) when heated with PhOH, giving the Franchimont-Bamberger reaction with $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ and Zn and being reconverted into (C) by treatment with H_2SO_4 (Reverdin's reaction). By a method analogous to that used in the synthesis of (A), M. and H. prepd. $p\text{-Me}_3\text{NC}_6\text{H}_4\text{NHAc}$ (F), needles, m. $132\text{--}3^\circ$ (Beilstein, IV, 588, gives 130°), which combines readily with MeI, forming the *methiodide* (G), prisms readily dissociating on attempted recrystn., which when treated with Ag_2O formed the *free base* which quickly absorbs CO_2 but which yielded a *picrate*, $\text{AcHNC}_6\text{H}_4\text{NMe}_3\text{OC}_6\text{H}_3(\text{NO}_2)_3$, yellow scales, m. $206\text{--}8^\circ$, and a *ferrocyanide*, $[\text{AcHNC}_6\text{H}_4\text{NMe}_3]_2\text{H}_2\text{Fe}(\text{CN})_6 \cdot 2\text{H}_2\text{O}$, which does not lose its H_2O at 100° . (G) when treated with AgNO_3 formed a *nitrate*, $\text{HNAC}_6\text{H}_4\text{NMe}_3\text{NO}_3$, flat needles, decomp. over a wide temp. range, reaching finally 225° , which could be nitrated in a cold mixt. of fuming HNO_3 and concd. H_2SO_4 , the appearance of a yellow deposit indicating the completion of the reaction. The product was shown to be *2,3,5-trinitro-4-trimethylammonium-1-benzoquinoneimide* (H), whose structure is probably represented by either (I) or (II), golden-yellow scales from EtOH, decomp. $200\text{--}20^\circ$.

(H) is probably the first true quinoneimide- NH_4 deriv. synthesized. Its properties have not been fully detd. and no derivs. have been prepd. It is unstable and its acid solns. when heated decomp. with gas evolution and the formation of an unidentified compd. volatile with steam. (H) dissolves in HCl forming a colorless soln. from which (H) can be regenerated on treatment with alkali. When nitrated (F) also yields (C). When allowed to react with HNO_3 , (F) forms a compound (containing 19.3% N, and apparently not a nitrosoamine), stumpy red prisms, m. $132-3^\circ$. On methylation $4\text{-O}_2\text{NC}_6\text{H}_4\text{NHCH}_2\text{Ph}$ yielded *benzylmethyl-p-nitroaniline*, silky yellow needles, m. $68-9^\circ$, which does not form quaternary NH_4 derivs. but which on reduction with Sn and HCl yields the corresponding *benzylmethyl-p-phenylenediamine* (I), whose *acetyl derivative*, slender needles, m. $110-1^\circ$, forms no quaternary NH_4 iodides, but on nitration gives rise to (C). A *disulfo* derivative of (I), $4\text{-(MeC}_6\text{H}_4\text{SO}_2)_2\text{NC}_6\text{H}_4\text{N-MeCH}_2\text{Ph}$, scales, m. 217° , was also prepd.

LOUIS E. WISE.

Walden Inversion. I. Influence of the solvent on the sign of the product in the conversion of phenylchloroacetic acid to phenylaminoacetic acid. GEORGE SENTER and HARRY G. K. DREW. Birkbeck Coll., London. *J. Chem. Soc.* 107, 638-42 (1915). —*d*- $\text{PhCHClCO}_2\text{H}$ was prepd. from mandelic acid and PCl_5 (cf. Bischoff and Walden, *Ann.* 279, 122) and resolved by means of its morphine salt (cf. McKenzie and Clough, *C. A.* 2, 2236). The isomers, crystd. from petroleum, m. 61° , $[\alpha]_D^{16}$ (3% PhH soln.) $\pm 185^\circ$. The influence of solvents on the reaction between NH_3 and these isomers was investigated. H_2O and MeCN were chosen as solvents since they form homogeneous solns. with the NH_4 salt and excess of NH_3 . In aq. soln. the reaction is attended by considerable racemization and the resulting $\text{PhCH}(\text{NH}_2)\text{CO}_2\text{H}$ always has the *opposite* sign to that of the $\text{PhCHClCO}_2\text{H}$ taken. A soln. of 0.75 g. *l*- $\text{PhCHClCO}_2\text{H}$ in 15 cc. H_2O was satd. with NH_3 and kept in a sealed Jena glass tube at 9° for 19 days. 2 crops of $\text{PhCH}(\text{NH}_2)\text{CO}_2\text{H}$ were isolated: 1st crop (0.25 g.), $[\alpha]_D^{16}$ 83.5° ; 2nd crop (0.02 g.), $[\alpha]_D^{16}$ 135.5° . (The pure *d*- and *l*- NH_2 acids have $[\alpha]_D^{16} \pm 157.9^\circ$). With MeCN as solvent, the reaction is also attended by appreciable racemization, but the sign of the resulting active NH_2 acid is invariably the same as that of the original Cl acid. The proportion of active NH_2 acid formed in MeCN appears to be practically independent of the temp. at which the reaction is carried out, being about the same at 9° as at 52° . 4 g. *l*-Cl acid in 70 cc. MeCN were satd. with dry NH_3 and kept for 24 hrs. at 52° . The product, after washing with a small amt. of H_2O to remove NH_4 salts, yielded 2 crops of crystals: 1st crop (2.25 g.), $[\alpha]_D^{16}$ (in 0.984 N HCl) -8.7° ; 2nd crop (0.2 g.), $[\alpha]_D^{16}$ -67° . An expt. carried out in MeCN, in which the *d*-Cl acid was used, yielded (in the 2nd crop) a product containing about 80% of *d*- NH_2 acid.

LOUIS E. WISE.

Salicylates. Lead and copper salicylates. W. O. DE CONINCK. *Bull. soc. chim.* 17, 164-7 (1915); cf. *C. A.* 9, 2058.—By gradually adding PbCO_3 to aq. $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$, kept at $70-5^\circ$, and allowing the mixt. to cool slowly, de C. obtained a *lead salicylate*, $(o\text{-HOC}_6\text{H}_4\text{CO}_2)_2\text{Pb} \cdot 2\text{H}_2\text{O}$ (A). Cahours (ref. not given) has described a monohydrate. When (A) is treated with NH_4OH , it is *not* converted into the pure basic salt $(\text{C}_6\text{H}_4\text{O}_3)_2\text{Pb}_3\text{PbO}$, which other investigators (not named) claim is produced when NH_4OH acts upon Pb salicylate. Instead, a mixt. of unidentified basic salts was obtained. In attempting to prep. the basic salicylate $\text{O.C}_6\text{H}_4\text{CO.O.Pb}$ (B), by gradually

heating (A) with PbO, de C. obtained a mixt. of (B) and smaller amts. of a Pb hydroxyisophthalate (no formula given). By treating a Ca salicylate soln. with an equivalent amt. of CuSO_4 , a normal *copper salicylate*, with 2 H_2O , was prepd. (Previous investigators have reported a tetrahydrate; ref. not given.) When heated with H_2O , EtOH, or even with Et_2O (at their resp. b. ps.?) (C) is converted into $\text{O.C}_6\text{H}_4\text{CO.O.Cu}$

and $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$. de C. bases the following general conclusions in part on the results of his previous investigations on Ba, Cd, Hg, Ca, Sr salicylates. Normal salicylates of divalent metals (M'') are apparently complexes of the basic salt and the free acid: $[(\text{O.C}_6\text{H}_4\text{CO.O.M}'')(\text{HOC}_6\text{H}_4\text{CO}_2\text{H})]$, which may be stable, decomp. only at

fairly high temps. into $\text{O.C}_6\text{H}_4\text{CO.O.M}''$, PhOH and CO_2 , or unstable, as in the case

of (C), decomp. very readily into the free acid and the basic salt. LOUIS E. WISE.

Dehydration and esterification of cyclohexanol and *p*-methylcyclohexanol by means of oxalic acid. A. JUÉRY. Boucicaut Hosp. *Bull. soc. chim.* 17, 167-75 (1915).—J. finds that the best conditions for dehydrating the cyclohexanols are obtained when 1 mol. of the hexanol is heated with 3 mols. of $(\text{CO}_2\text{H})_2$, *p*-methylcyclohexanol (A) yielding 50-5% of *p*-methylcyclohexene (B) and cyclohexanol (C) yielding 70-5% of cyclohexene (D). Unchanged (A) and (C) were the only other reaction products recovered. If <3 mols. of $(\text{CO}_2\text{H})_2$ are used, normal oxalates may also be formed. Thus, 1 mol. of (A), when heated with 1 mol. of $(\text{CO}_2\text{H})_2$, yielded roughly 25% of (B) and 25% of a mixt. of 2 isomeric *p*-methylcyclohexyl oxalates (E), needles, m. 98° , b₂₇ $192-3^\circ$, and (F), oil, b₁₈ $198-9^\circ$, d₄ 1.044, possessing an aromatic odor and failing to cryst. in ice- CaCl_2 mixt. When 0.5 mol. $(\text{CO}_2\text{H})_2$ is heated for 12 hrs. with 1 mol. of (A), very little dehydration takes place, but the yield of esters increases. Ordinarily the ester mixt. obtained above contains 33% of (E) and 66% of (F). Both (E) and (F) on sapon. with dil. NaOH yield (A), readily identified by means of its phenylurethan, m. 125° . 1 mol. of (C) when heated with 0.25 mol. of $(\text{CO}_2\text{H})_2$ yields largely unchanged (C), practically no (D) and a very appreciable amt. of *cyclohexyl oxalate*, needles, m. 45° , b₁₈ $190-1^\circ$. No isomeric liquid oxalate was obtained in this case.

LOUIS E. WISE.

Aspirin. II. Formation of aspirin. D. E. TSAKALOTOS AND S. HORSCH. Univ. Athens. *Bull. soc. chim.* 17, 186-90 (1915); cf. C. A. 9, 787.—T. and H. have detd. the rate of formation of aspirin from Ac_2O and $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ in PhH, at 25° , 30° , and 50° . The course of the reaction, which is of the 2nd order, was followed by detg. the change in acidity of the mixt., by titrating aliquot portions with 0.02 N $\text{Ba}(\text{OH})_2$ at frequent intervals. The velocity const. K was detd. by the solution of the equation: $[\log a_t + \log (a_0 - a_f) - \log a_0 - \log (a_t - a_f)]/a_f t = 0.4343 K$, where a_0 = the initial titer of the mixt. in terms of 0.02 N alkali, a_t = titer at the end of a time interval t , and a_f = the titer at equil. The following mean values for K were found at 25° , 30° , and 50° , resp.: 0.000148, 0.000246, 0.00115. The increase in the rate of formation of aspirin with rising temp. reaches its limit at 90° , above which aspirin itself undergoes decompn. with the formation of Ac_2O and $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$.

LOUIS E. WISE.

Nitration of dimethyl-*m*-phenetidine. FRÉDÉRIC REVERDIN. Univ. Geneva. *Bull. soc. chim.* 17, 190-6 (1915).—*m*- $\text{EtOC}_6\text{H}_4\text{NMe}_2$ (A), b. 256° , was obtained in 86% yield, by the action of Me_2SO , on $\text{EtOC}_6\text{H}_4\text{NH}_2$. 2 g. (A) in 20 cc. Ac_2O , when treated with 10 cc. HNO_3 (d. 1.52) at room temp., yielded 4,6-dinitro-3-methylnitroamino-1-ethoxybenzene (B), $(\text{O}_2\text{N.NMe})(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{OEt}$, colorless prisms, m. $137-8^\circ$, which, when heated on a H_2O bath with alc. KOH and the resulting product decompd. with HCl, yielded

3,4,6-(MeHN)(O₂N)₂C₆H₃OH, m. 182° (cf. *Ibid* [4] 3, 126). When heated at 70° until fumes were evolved, a mixt. of 3 cc. of (A) in 25 cc. AcOH and 10 cc. HNO₃ (d. 1.4) yielded 4,6-dinitro-3-nitrosomethylamino-1-ethoxybenzene (C), nearly colorless needles, m. 113-4°. If the above reaction is allowed to proceed at about 12°, and the mixt. poured into H₂O as soon as the evolution of brown fumes is noted, 4,6-dinitro-3-dimethylamino-1-ethoxybenzene (D), yellow needles, m. 172°, and small amts. of (C) are obtained. (C) in Ac₂O was converted into (B), on treatment with HNO₃ (d. 1.5) on the H₂O bath. When heated with boiling, fairly concd. HCl for an hr., (C) is converted in 4,6-dinitro-3-monomethylamino-1-ethoxybenzene, yellow needles, m. 210°, also formed by heating (B) with PhOH. R. also prepd. (from dimethylanisidine) 4,6-dinitro-3-methylnitrosoamino-1-methoxybenzene, lemon-colored needles, m. (poorly) about 115°, by a reaction similar to the one giving rise to (C), but carried out at 45°.

LOUIS E. WISE

Molecular rearrangements of triphenylmethane derivatives. J. STIEGLITZ WITH ISABELLE VOSBURGH, AGNES F. MORGAN, BERT A. STAGNER AND JAMES K. KUHN SENIOR. Univ. Chicago. *Proc. Nat. Acad. Sci.* 1, 196-210(1915); cf. *C. A.* 8, 1276, 3785.—The following rearrangements are recorded: Ph₃CNHBBr to Ph₃C:NPh (a) in the presence of NaOH, Ca(OH)₂ or MeONa. (p-ClC₆H₄)₂PhCNHCl to a mixt. of (ClC₆H₄)₂C:NPh and (ClC₆H₄)PhC:NC₆H₄Cl; (BrC₆H₄)(ClC₆H₄)PhCNHCl underwent a similar change. Ph₃CNCl₂ to (a) with explosive violence under the influence of heat alone. (Ph₃CNMeCl is not rearranged either by bases or heat.) Ph₃CNMeOH, previously described as rearranging only slightly, to Ph₃C(OH)NMePh (or its chloride) by the action of PCl₅ on the Et₂O soln. ClC₆H₄Ph₃CNMeOH to a mixt. of Ph₃C(OH)N-MeC₆H₄Cl and ClC₆H₄PhC(OH)NMePh. Ph₃CN₂ to (a) when heated at high temp.; ClC₆H₄Ph₃CN₂ to mixt. of ClC₆H₄PhC:NPh and Ph₃C:NC₆H₄Cl. Ph₃CNHNH₂ could not be rearranged by either acids or ZnCl₂, while (Ph₃CNH), under the influence of ZnCl₂ gave a product from which PhNH₂ was obtained, indicating that a rearrangement had taken place; this behavior, corresponding to that of NH₂OH derivs., is the 1st such rearrangement to be observed in the (NH₂)₂ series. The above changes are used by S. as further support for his theory that such rearrangements are to be explained by a consideration of the electron valencies and the great tendency of the unstable Cl⁺ and OH⁺ to go over into their common stable negative forms. This paper, which contains only brief exptl. data, is apparently a preliminary report.

NORMAN A. SHEPARD.

Constitution of organic compounds in relation to their absorption of light. E. C. C. BALY. Liverpool. *J. Soc. Chem. Ind.* 34, 393-9(1915); cf. *C. A.* 9, 1577.—Exptl. evidence, in the nature of absorption curves, is here introduced to support B.'s theory that color change, or change in absorption of light, is due not to a change in structure, but to an opening up of the mol. fields of force. The curves for PhOH in neutral and in alk. soln. are given, showing an absorption of different wave lengths in the different solvents. According to B., 3 different stages of the opening up of the force field of PhOH are to be considered, with powers of absorbing wave lengths of approx. 2900, 2720 and 2400, resp., as shown by the absorption bands. The curves for diphenyl-violic acid and some of its salts are included to explain the wide variation in color of these salts; curves for p-nitroaniline and p-nitrophenol in different solvents are also given.

Action of nitrous acid on the amines. PANCHANAN NEOGI. Rajshahi, India. *Chem. News* 111, 255(1915); cf. *C. A.* 8, 3024; see also *C. A.* 6, 593; 7, 338, 2925.

NORMAN A. SHEPARD.

Difflavone group. I. Difflavone. HUGH RYAN AND PAULINE O'NEILL. Univ. Coll., Dublin. *Proc. Roy. Irish Acad.* 32, 48-56(1915).—Difflavone may be synthesized

by two methods from diacetoresorcinol (a). 2.0 g. (a) di-Me ether (b), prepd. by the action of Me_2SO_4 on (a) in the presence of KOH, condenses readily with 2 cc. BzH when warmed for a short time in 25 cc. alc. with 1 cc. 50% NaOH, forming *o,o*-dibenzylidenediacetoresorcinol dimethyl ether, $1,5,2,4\text{-C}_6\text{H}_2(\text{OMe})_2(\text{COCH:CHPh})_2$ (c), light yellow prisms from C_6H_6 , insol. in dil. KOH, m. $156\text{--}7^\circ$. (c) may be demethylated by HI, but the product is oily; boiled in $\text{C}_6\text{H}_5\text{Me}_2$ with AlCl_3 , *o,o*-dibenzylidenediacetoresorcinol (*o,o*-dihydroxydichalcone) (d) is formed, but the yield is poor. (d) seps. in yellow cubes, m. $196\text{--}8^\circ$; it may also be prepd. by allowing (a) to stand with BzH in very dil. NaOH for 5 weeks. 1.0 g. (c) in 10 cc. CHCl_3 with 0.85 g. Br, sepd., on addition of alc., the *dihydroxydichalcone dimethyl ether tetrabromide*, $\text{C}_6\text{H}_2(\text{OMe})_2(\text{COCHBrCHBrPh})_2$ (e), prisms from MePh, m. $185\text{--}6^\circ$ (decompn.). Heated in $\text{C}_6\text{H}_5\text{Me}_2$ with AlCl_3 , (e) did not give diflavone. *Dihydroxydichalcone diacetate tetrabromide*, $\text{C}_6\text{H}_2(\text{OAc})_2(\text{COCHBrCHBrPh})_2$ (f) is formed on boiling 1.0 g. (d) with 1.0 g. AcONa and 10 cc. Ac_2O , pouring into H_2O , sepg. the oil, after washing in Et_2O with Na_2CO_3 , and then adding 0.8 g. Br to the CHCl_3 soln. at ordinary temp.; it seps. from MePh in needles, m. $176\text{--}8^\circ$. 0.5 g. (f), dissolved in 7.8 cc. 0.5 *N* alc. KOH, sepd. *diflavone* $\text{O.CPh:CH.CO.C}_6\text{H}_2\text{CO.CH:CPh.O}$ (g), on short warming, faintly yellow needles

from MePh. It was not quite pure, being contaminated with a little dibenzylidenedicoumarone; it was obtained in purer condition by the following method: 10.0 g. (b) condensed with 100 cc. BzOMe in the presence of 4.2 g. Na gave 5.0 g. *dibenzoylaceto*resorcinol dimethyl ether, $\text{C}_6\text{H}_2(\text{OMe})_2(\text{COCH}_2\text{Bz})_2$ (h), light yellow plates from C_6H_6 , sol. in aq. KOH, m. $200\text{--}1^\circ$. While (h) is not affected by boiling with HI (d. 1.5), it is converted on heating 1 hr. at 135° with HI (d. 1.7) into *2-benzoylacetato-3-methoxyflavone*, $\text{MeO(BzCH}_2\text{CO)C}_6\text{H}_2\text{CO.CH:CPh.O}$ (i), faintly yellow prisms, m. 238° .

Heated for 5 hrs. with HI (d. 1.7) under the same conditions, (h) gives (g), yellow needles, softens 275° , m. $281\text{--}2^\circ$; sol. in concd. H_2SO_4 with a faint yellow color and brilliant blue fluorescence. Neither of the above methods of prepn. is as smooth as in the monoflavone series.

NORMAN A. SHEPARD.

Condensation of aldehydes with β -diketones. HUGH RYAN AND J. M. DUNLEA. Univ. Coll., Dublin. *Proc. Roy. Irish Acad.* 32, 57-64(1915); cf. *C. A.* 9, 75.

NORMAN A. SHEPARD.

Betaines and quaternary salts. ALBERT B. WEINHAGEN. Kgl. Sächs. Tech. Hochschule, Dresden. *Separate*, 55 pp.—The behavior of several heterocyclic bases of the type of pyridine (a) and quinoline (b) toward $\text{PhCHClCO}_2\text{H}$ (c) was investigated with the expectation of forming new betaine derivs. While (b) added (c) normally and (a) also gave an addition product, in the latter case CO_2 was evolved and no betaine was obtained. The same behavior was noted with $\text{MeCHClCO}_2\text{H}$ and (a). The action of (c) on different derivs. of both these bases was then studied; $\alpha\text{-C}_6\text{H}_4\text{NMe}$ (d) did not react at all, while $\alpha\text{-C}_6\text{H}_4\text{NMe}$ (e) behaved like (a). $2,4,6\text{-C}_6\text{H}_2\text{NMe}_3$ (f) did not add directly, nor was CO_2 evolved, but HCl was removed from (c) with the formation of (f)-HCl. The non-formation of addition products in the cases of (d) and (f) may be due to steric hindrance according to W. since both *o*-positions to the N are occupied. To further support this view, he finds that neither (d) nor (f) gives addition products with $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Cl}$. The fact that (f) is a very much stronger base than any of the other bases employed is proposed to explain its behavior in removing HCl from the α -halogen acid. In these reactions the components were usually heated together at 100° without solvents for 2-3 hrs., the base being in slight excess. Where no cryst. product sepd., the excess of base was distd. with steam and the addition product then pptd. and identified by means of some double salt. *Benzylpyridinium*

chloroaurate, from (a) and (c), yellow needles, m. 107-9°. (b) and (c) gave *quinoline-phenylbetaine hydrochloride*, $\text{C}_{10}\text{H}_7\text{CHPhCO}_2\text{H}$; the salts are all unstable in hot H_2O ; *chloromercurate*, pptd. cold, shrinks 56°, m. 140°; *perchlorate*, bright orange, m. 120° (decompn.); the dichromate, chloroplatinate and -aurate are all unstable. (e) with (c) evolved CO_2 with the formation of *benzyl- α -picolinium chloride*; *chloroaurate*, m. 133-4°; *chloroplatinate*, fine flesh-colored crystals from H_2O , m. 212-3°; *dichromate*, oil, crysts. on standing, m. 129°; *chloromercurate*, oil. Collidine-HCl, obtained from (f) and (c) and previously described by Möhler as having no m. point, partially m. 55-7°, solidifies, darkens 240° and finally m. 266-8° (decompn.). Nicotine (g) heated with (c) gave *monobenzylnicotininium chloride*, $\text{C}_{10}\text{H}_{14}\text{N}_2\text{C}_7\text{H}_7\text{Cl}$ (h), which was identified through its *chloroplatinate*, pink crystals, m. 236° (decompn.); *chloroaurate*, m. 178° (decompn.) and seps. Au on boiling with H_2O ; NH_4 picrate ppts. a *picrate*, $\text{C}_{10}\text{H}_{14}\text{N}_2\text{C}_7\text{H}_7\text{C}_6\text{H}_3(\text{NO}_2)_3\text{O}$, as an oil, crysts. on standing. It partially decomps. 99°, m. 122°. For comparison the behavior of PhCH_2Cl (i) toward (g) was investigated. With 2 mols. (i) a hygroscopic product was formed, whose salts analyzed for dibenzylnicotininium chloride; *chloroaurate*, m. 170-83° (decompn.), is decompd. by hot H_2O ; *chloroplatinate*, shrivels 205°, m. 211° (decompn.); *picrate*, $\text{C}_{10}\text{H}_{14}\text{N}_2(\text{C}_7\text{H}_7)_2\text{C}_6\text{H}_3(\text{NO}_2)_3\text{O}$, m. 122° (cf. Ber. 25, 1433). One mol. each of (g) and (i) gave (h). (a) heated with $\text{MeCHClCO}_2\text{H}$ gave ethylpyridinium chloride, with the evolution of CO_2 ; *chloroaurate*, m. 190° (decompn.). *o*-Nitrobenzylpyridinium chloride, from *o*- $\text{NO}_2\text{C}_6\text{H}_4\text{CH}_2\text{Cl}$ (j) and (a), previously prepd. by Lellmann and Pekrun (Ann. 259, 57), gave a *chloromercurate*, colorless plates, m. 145°; *dichromate*, m. 172°; *perchlorate*, $\text{C}_{15}\text{H}_{11}\text{N}_2\text{O}_3\text{ClO}_4\text{H}_2\text{O}$, m. 154°; *chloroplatinate*, m. 223°, decomps. 228°; *picrate*, needles from H_2O , m. 148°. (j) forms *o*-nitrobenzyl- α -picolinium chloride with (e), pptd. from alc. by Et_2O , m. 115°; *chloroaurate*, small crystals from H_2O , m. 132-3°. *o*-Nitrobenzylquinolinium chloride; *dichromate*, chars 190-200°. *o*-Nitrobenzylnicotininium chloride; *chloroplatinate*, m. 227-9°; *chloroaurate*, m. 192-4° (decompn.); *dichromate*, m. 110°. *m*-Nitrobenzylpyridinium chloride, $(\text{C}_6\text{H}_5\text{NCICH}_2\text{C}_6\text{H}_4\text{NO}_2)_2\cdot 3\text{H}_2\text{O}$, fine leaves, m. 97-9°; *chloromercurate*, needles, m. 117-9°; *dichromate*, m. 189° (decompn.); *perchlorate*, needles, m. 142°; *picrate*, yellow needles, m. 142°; *chloroplatinate*, m. 213-5°. *m*-Nitrobenzyl- α -picolinium chloride, pptd. from alc. by Et_2O , fine needles, m. 118°; *chloroaurate*, small yellow crystals, m. 159°. *m*-Nitrobenzylquinolinium chloride; *dichromate*, m. 190° (decompn.). *m*-Nitrobenzylnicotininium chloride; *chloroplatinate*, m. 204-5° (decompn.); *chloroaurate*, m. 185° (decompn.) and seps. Au when suspended in cold H_2O . *p*-Nitrobenzylpyridinium chloride, $(\text{C}_6\text{H}_5\text{NCICH}_2\text{C}_6\text{H}_4\text{NO}_2)_2\cdot 3\text{H}_2\text{O}$, m. 64-6°; *chloromercurate*, needles or plates from H_2O , m. 137°; *perchlorate*, needles from H_2O , m. 131°; *dichromate*, m. 73-5°; *picrate*, yellow needles, m. 171°; *chloroplatinate*, leaves from H_2O , m. 210-1° (decompn.). *p*-Nitrobenzylnicotininium chloride; *chloroaurate*, m. 80° (decompn.); *chloroplatinate*, m. 223°. *p*-Nitrobenzyl- α -picolinium chloride, hygroscopic yellow crystals, decomps. in the air; *chloroaurate*, m. 159°, is decompd. by long boiling with H_2O ; *chloroplatinate*, needles, m. 217°; *chloromercurate*, clusters of needles, m. 139-40°. *p*-Nitrobenzylquinolinium chloride; *dichromate*, m. 176°. (f) heated with a small excess of PhCHO for 3 hrs. is converted into 2,4-dimethyl-6-benzalpyridine, yellow oil, which cannot be distd. without decompn.; *chloromercurate*, $\text{Me}_2(\text{CH}:\text{CHPh})\text{C}_6\text{H}_2\text{N}\cdot\text{HCl}\cdot\text{HgCl}_2$, green, m. 226°; *chloroplatinate*, $(\text{C}_{15}\text{H}_{15}\text{N}\cdot\text{HCl})_2\text{PtCl}_4\cdot\text{H}_2\text{O}$, yellow powder, m. 236-8°. MeCHO and $\text{NO}_2\text{C}_6\text{H}_4\text{CHO}$ do not condense with (f), while CCl_3CHO apparently forms an extremely unstable substance (cf. Ann. 265, 208). Basic collidine *chloromercurate*, $\text{C}_8\text{H}_{11}\text{N}\cdot\text{HgCl}_2$, m. 155°; collidine *perchlorate*, m. 233°. Cautiously heated with concd. HNO_3 , pyridinebetaine (k) is converted into pyridinebetaine nitrate (J. prakt. Chem. 43, 280); heated for 4-5 hrs. with concd. HNO_3 at 180° in a closed tube, (a) is obtained. (k) heated at 250° with P + HI also gave (a). Sn + HCl also failed to reduce (k). In an attempt to prep. α,α' -tetramethylpyrrolidine (l) from $(\text{HOCMe}_2$

$(CH_3)_2$, $ZnCl_2 \cdot NH_3$ was used, heating at 200° for 2 hrs.; the amt. of (I) was very small, for another compd. accompanied it, which was probably α, α' -tetramethyltetramethylene oxide, $CH_3 \cdot CMe_2 \cdot O \cdot CMe_2 \cdot CH_3$.

NORMAN A. SHEPARD.

Preparation of methylamine. II. S. ISONO. *J. Pharm. Soc. Japan* 1915, No. 397, 209; cf. *Ibid* 1911, No. 356, 678.— $MeNH_2$ is formed in 60% yield on heating $NH_4CH_2SO_3H$ (a) at 180 – 190° . The melt is dissolved in H_2O , the soln. filtered from S, made alk. with NaOH and then distd. into HCl. The HCl soln. is evapd. to dryness and the $MeNH_2 \cdot HCl$ extd. with abs. alc. This amine is also obtained, in the form of $MeNH_2SO_3H$, when a concd. soln. of $HOCH_2SO_3NH_4$ is heated with NH_4HSO_4 at 145 – 50° . (a) is also formed and is considered as the primary product of the reaction. (a) was isolated in two distinct cryst. forms: hexagonal prisms, m. 192 – 3° , previously described (cf. *Chem. Zentr.* 1905, I, 990), and groups of rhombic leaves, m. 182 – 3° . In a finely pulverized state, both forms m. 177 – 8° . When either $(CH_3)_3N_4$ or a mixt. of HCHO and NH_4Cl are shaken with Pt black and H_2 , Me_3N is chiefly formed (60%), with a little $MeNH_2$ and Me_2NH (together about 10%).

NORMAN A. SHEPARD.

Preparation of formic and oxalic acids. SHOSAE MON KEIMATSU AND BUNJI IKEDA. *J. Pharm. Soc. Japan*, 1915, No. 399, 499.— HCO_2Na is formed in 79% yield when CO acts on 1 part each of pulverized NaOH and MgO at high temp., even when the gas is not applied under pressure. NaOH-MgO has the advantage over soda-lime that it does not cake at high temps., thus allowing the interruption of the process at will, a thing impossible in the soda-lime process, where the stirring must be continuous. After complete absorption of the CO, it is only necessary to treat with H_2O , filter from the MgO, and evap. to dryness. Where $(CO_2H)_2$ is to be prepd. from this product, crude NaOH may be used in prepg. the HCO_2Na , but the MgO must be first removed, for with the HCO_2Na -MgO mixt. the formation of $(CO_2H)_2$ is very incomplete.

NORMAN A. SHEPARD.

Commercial chrysarobin. ROBERT EDER. *Zurich. Arch. Pharm.* 253, 1–32 (1915).—The investigation was confined to expts. with oxidation products of chrysarobin (A). Fifty g. Merck's (A) triturated with a little 1% NaOH was washed into a cylinder with 1000 cc. of the same soln. Air was then passed through the mixt. some hrs. at the ordinary temp., whereby a large part of (A) dissolved with a deep red color. The presence of H_2O_2 could be detected in the liquid. The mixt. was next filtered and the insol. portion again treated with fresh 1% NaOH and air, followed by filtration as before. This procedure was continued until only faintly reddish caustic liquors resulted. The sol. portion of oxidized (A) proved to be frangula emodin (about 0.2%) and methoxylated chrysophanic acid (about 32%), of which some 29% consisted of emodin mono-Me ether and 71% chrysophanic acid. Triacetylemodin m. 197° . That portion of oxidized (A) insol. in cold 1% NaOH consisted of 28% dark violet to brownish amorphous secondary oxidation products and 18% dehydroemodinanthranol

mono-Me ether (B), $HO \cdot C_6H_3 \cdot \begin{array}{c} \diagup C \\ \diagdown O \end{array} \cdot C_6HMe(OMe)OH$, isolated by acidifying

the insol. portion of oxidized (A) and subsequent washing and triturating with 10% Na_2CO_3 , evapg. to dryness on the steam bath and extg. the residue with C_6H_6 . On concn., the orange-yellow C_6H_6 soln. yielded (B), as light yellow felted needles darkening 230 – 45° , m. 250 – 6° to a shiny black green mass, sol. in 230 parts boiling C_6H_6 and 350 parts boiling AcOH, very slightly sol. in alc., ligroin and C_6H_6 , somewhat more so in acetone, easily sol. in cold concd. H_2SO_4 with orange-red color, which is unaffected by the addition of $B(OH)_3$, but on standing, or more quickly on warming, becomes green.

Solns. of (B) in C_6H_5N , $PhNH_2$, $PhNO_2$ also become green. HI converts (B) into emodinanthranol, nascent H ($Zn + AcOH$) into emodinanthranol mono-Me ether, m. $186-7^\circ$, $BzCl$ into a dibenzoate. Tutin and Clewer's statement to the effect that (B) darkens in soln. could not be verified. It is unaffected by Me_2SO_4 as well as hot concd. aq. NH_3 ; insol. in cold 1-2% $NaOH$, sol. in cold 5% $NaOH$ with yellow color, gradually becoming brown in contact with the air. Emodinanthranol mono-Me ether, likewise insol. in 1% $NaOH$, assimilates O on treatment with air in alk. suspension, passing thereby into emodin mono-Me ether, sol. in the alk. liquid with a red color. On similar treatment, (B) remains unchanged but is oxidized by CrO_3 to emodin mono-Me ether. The dibenzoate of (B), $C_{30}H_{30}O_6$, forms aggregates of needles from $C_6H_6 + benzine$, sinters 182° , softens 185° and remains thus without melting up to 210° , easily sol. in alc., C_6H_6 and $AcOH$, only slightly so in Et_2O , ligroin and petr. ether; reduced by Zn and boiling $AcOH$ to the emodinanthranol mono-Me ether dibenzoate, which, however, could not be prepd. in cryst. form; converted into dibenzoylmodin mono-Me ether by CrO_3 in $AcOH$, faintly yellow felted needles, m. 228° . Attempts to convert (B) into dehydroemodinanthranol by means of demethylation were unsuccessful. From the fact that (B) is a normal constituent of (A) and unaffected by air oxidation in 1-2% $NaOH$, it is found in the non-oxidized portion sep'd. by filtration. The original (A) likewise contains emodin, emodin mono-Me ether and chrysophanic acid as such or perhaps in partly reduced form as easily oxidizable anthranols. Finally, other unidentified substances very likely occur in minute quantity in the original material and later appear as dark amorphous products after the alk. treatment with air. The substances, chrysophanic acid Me ether and chrysarobol, reported by Hesse as being constituents of (A), were not found in the products of oxidation. The presence of dichrysarobin Me ether reported by Jowett and Potter is questioned. W. O. E.

2-Hydroxy-3-methoxybenzaldehyde. E. RUPP AND K. LINCK. Univ. Koenigsberg. *Arch. Pharm.* **253**, 33-41 (1915).—The aldehyde (a) recrystd. from ligroin forms bright greenish yellow needles m. $44-5^\circ$, dissolves in alk. carbonates and caustic alkalis with an intense yellow color and imparts an intense coloration to animal tissue. *Oxime*, needles, m. 121° . *Asine*, $[HO(MeO)C_6H_3CH:N]_3$, yellow needles, m. 196° . *Anilide*, $HO(MeO)C_6H_3CH:NPh$, orange needles, m. 84° . *Phenylhydrazone*, yellow needles, m. 128° . *2,3-Dimethoxybenzaldehyde*, from (a), Me_2SO_4 and $NaOH$, needles, m. $54-5^\circ$. *2-Benzoyloxy-3-methoxybenzaldehyde*, needles, m. 90° . *2-Benzsulfuryloxy-3-methoxybenzaldehyde* (b), $PhSO_3(MeO)C_6H_3CHO$, leaflets, m. 121° . *Acetoxymethoxybenzaldiacetate*, $AcO(MeO)C_6H_3CH(OAc)_2$, light yellow crystals, m. 83° , from (a) and a large excess of Ac_2O and a few drops of concd. H_2SO_4 . There is also formed in much smaller quantity an insol. compd. m. 236° , which, however, constitutes the chief product when the principal reacting substances are employed in equimol. proportions. *5-Nitro-2-hydroxy-3-methoxybenzaldehyde*, by the action of 65% HNO_3 , bright yellow needles, m. 142° . *5-Bromo-2-hydroxy-3-methoxybenzaldehyde*, yellow needles, m. 127° . Toward oxidizing agents, (a) shows great stability; if reacting at all it is usually through the OH group. *2,3-Hydroxymethoxybenzoic acid*, by the action of $KMnO_4$ on (b) in the presence of $MgSO_4$ and subsequent sapon. of the resulting *benzsulfuryloxymethoxybenzoic acid* (leaflets, m. 195°) with 3% $NaOH$, leaflets, m. 148° . *Silver salt*, white ppt. *Methyl ester*, crystals, m. $67-8^\circ$. On fusion with KOH , (a) yields quant. at about 215° the acid above. With Et_2O and $AcONa$ at $180-200^\circ$, (a) gives as the main product *2-hydroxy-3-methoxy- β -phenylacrylic lactone*, $MeOC_6H_3CH:CH.CO.O$, needles,

m. 89° . Na-Hg converts the lactone into *2-hydroxy-3-methoxy- β -phenylpropionic lactone*, needles, m. 107° . The *dibromo derivative*, $C_{10}H_5O_2Br_2$, satiny needles, m. 165° .

W. O. E.

Ephedrine and pseudoephedrine. ERNST SCHMIDT. Univ. Marburg. *Arch. Pharm.* **253**, 52-61 (1915).—I. **Phenylmethaminopropane.** According to a previously enunciated assumption and in harmony also with views entertained by Gadammer, the reversibility of the reaction involved in the change of ephedrine (I) into pseudo-

ephedrine (II) is conditioned upon a mol. rearrangement. This view finds further substantiation in the behavior of phenylmethaminopropane toward HCl. The hydrochloride $\text{C}_{10}\text{H}_{15}\text{N} \cdot \text{HCl}$ of this slightly *d*-rotatory base (from either ephedrine or pseudoephedrine) becomes stable after heating with 10 vols. 25% HCl 12 hrs. in a tube at H_2O bath temp., leaflets or plates from boiling acetone, m. 172° , $[\alpha]_D^{25} 17.8^\circ$ (0.2766 g. in 25 cc. H_2O); chloroplatinate, large reddish yellow needles from dil. HCl, m. $208-9^\circ$; aurate, large shiny needles from dil. HCl, m. 126° . II. **Methylephedrine methohydroxide.** Former expts. demonstrated that this compd. (a) on distn. suffers decompn. in accordance with the equation: $\text{PhCH(OH)CHMeNMe}_2\text{OH} = \text{NMe}_3 + \text{C}_9\text{H}_{10}\text{O} + \text{H}_2\text{O}$. The product, $\text{C}_9\text{H}_{10}\text{O}$, proved to be a mixt. of EtBz and phenylpropylene oxide, most of the latter, however, taking up H_2O with the formation of phenylpropylene glycol. On taking up the investigation anew, Eberhard found that even at the ordinary temp. (a) in aq. soln. yields some methylephedrine according to the equation: (a) = $\text{MeOH} + \text{PhCH(OH)CHMeNMe}_2$, while distn. of the aq. soln. favors the reaction in much greater degree. Under the influence of aq. vapor, methylephedrine thereupon passes into ephedrine and MeOH : $\text{PhCH(OH)CHMeNMe}_2 + \text{H}_2\text{O} = \text{PhCH(OH)CHMeNHMe} + \text{MeOH}$. This reaction takes place also when methylephedrine is repeatedly evapd. on the H_2O bath with HCl. A portion of ephedrine thus regenerated unites with phenylpropylene oxide (formed as above) to yield the very stable addition product, $\text{C}_{11}\text{H}_{18}\text{O}_2\text{N}$, the amt. of which is very small compared with that of NMe_3 , methylephedrine and ephedrine. III. **Methylephedrine methiodide.** Eberhard studied the action of Na-Hg on the hot concd. soln. of this compd. and found that partial demethylation takes place with the formation of methylephredine and ephredine and at the same time decompn. into NMe_3 and phenylpropylene oxide, the latter product uniting for the most part with a portion of ephedrine to form the above-mentioned addition product, ephedrinephenylpropylene oxide, $\text{C}_{11}\text{H}_{18}\text{O}_2\text{N}$. It is not improbable that this compd., which was also prepd. directly from its components, is a mixt. of the isomers (III)

and (IV), for the reason that the m. p. of the H_2O -sol. hydrochloride lies between 142 and 148° . Ephedrinephenylpropylene oxide is a tertiary base containing 2 OH groups, crystg. from alc. or Et_2O in plates, m. 125° , very slightly sol. in H_2O and having an alk. reaction, stable towards 25% HCl and Na-Hg . The hydrochloride, $\text{C}_{11}\text{H}_{18}\text{O}_2\text{N} \cdot \text{HCl}$, cubical or plate-like crystals sintering $146-8^\circ$, m. $155-6^\circ$ (feeble effervescence). The aurate, $\text{C}_{11}\text{H}_{18}\text{O}_2\text{N} \cdot \text{HCl} \cdot \text{AuCl}_3$, pale yellow needles, m. $144-5^\circ$. W. O. E.

The anhydrohydroxylamino compounds of unsaturated ketones. L. FRANCESCONI AND G. SANNA. *Ist. chim. farm., Cagliari. Gazz. chim. ital.* **45**, I, 35-41 (1915).—Pulegonehydroxylamine (a) gives, by the loss of H_2O , as was shown by Semmler (*Ber.* **37**, 950), anhydropulegonehydroxylamine, to which S. assigned the formula of an NH base (I). Similarly, Harries (*Ber.* **31**, 1380) obtained an anhydro compd. from

diacetonehydroxylamine which he considered to be trimethyldihydroisoxazole, $\text{NH.CMe}_2\text{CH:CMe.O}$. Since santolinone, the constitution of which is similar

to that of pulegone (*Gazz.* 44, II, 150), gives an NH base under similar conditions, it seems to be a general property of the NHOH compds. of α,β -unsatd. ketones, the double bond of which is outside of the nucleus, to give anhydro bases. Moreover, it was found that such anhydro bases may also be prepd. by H.'s method and that his isooxazole is an NH base. Likewise it was found that several NHOH compds. undergo a mol. rearrangement under the action of HCl in Et_2O to give a ketoxime. (a) was prepd. according to Bekmann's method by heating pulegone in Et_2O -EtOH with the calcd. amt. of $\text{NH}_2\text{OH.HCl} + \text{NaHCO}_3$ for 2 hrs., m. 157° . (a) treated in Et_2O with dry HCl gas gives a small amt. of the base obtained by Semmler as was shown by its index of refraction, its solubility, its odor, its picrate, etc. A secondary reaction also takes place. When the action of HCl is more prolonged the anhydro base is no longer obtained but a mixt. of oily bases, a solid and the free ketone. The pulegone was removed by distn. and the red-brown residue in EtOH sepd. crystals, m. $117-8^\circ$, which, decompd. with NaHCO_3 , gave crystals m. 157° , and finally some prismatic crystals, m. 141° , which do not reduce Fehling soln. except after treating with HCl, which does not give a NO compd. with HgO like hydroxylamines and hydroxylamino oximes, and which seems to be the normal pulegone oxime (II). This compound will be discussed further in a later paper. Camphorophorone in Et_2O -EtOH boiled with $\text{NH}_2\text{OH.HCl} + \text{NaHCO}_3$ gave camphorophoronehydroxylamine (b), m. 20° . (b) in Et_2O with HCl gas gives anhydrocamphorophoronehydroxylamine (III), an oil with the odor of conine, more sol. in cold than hot H_2O , sol. in org. solvents, reduces Fehling soln. only on heating, shows many reactions of alkaloids, does not react with HgO and is optically inactive; hydrochloride, non-cryst.; picrate, crystals with difficulty. Trimethyldihydroisoxazole has therefore by analogy not the formula given above but is an NH base, anhydrodiacetonehydroxylamine, $\text{NH.CMe}_2\text{CHAc}$. On standing with H_2O (III) goes over apparently

into camphorophorone oxime, m. 115° ; oxalate, m. 170° .

E. J. WITZEMANN.

The formula of santolinone. L. FRANCESCONI AND N. GRANATA. Univ. Cagliari. *Gazz. chim. ital.* 45, I, 167-81 (1915).—It was shown that α -santolinone is optically inactive through racemism (*C. A.* 9, 1040). In the proof of this the behavior of the hydroxylamine oxime and oxime with dil. acids was utilized. The action of acids on these derivs. has been used for reobtaining the ketone for the majority of hydrocyclic ketones. The NH_2OH is first eliminated from the double bond and then by hydrolysis the ketone is regenerated from the oxime. With α -santolinonehydroxylamine oxime (a), however, this action takes place quite differently and is similar to the effect on pulegonehydroxylamine. Of the simple ketones, $\text{C}_{10}\text{H}_{16}\text{O}$, the NH_2OH deriv. of pulegone alone is known. It is a bicyclic base, more sol. in cold than hot H_2O , is a weak base and its hydrochloride loses HCl easily and reduces Fehling soln. and AgNO_3 in the cold. The decompn. of (a) is gradual, thus:

and an oily imine is formed. When the intermediate imine oxime is treated further with acid, the nucleus to which the oxime group is attached is opened and a mol. of H_2O is eliminated with the formation of an anhydrohydroxylamine oxime, which has ordinary reducing powers and which is probably a nitrileimine, $CH_3:C(CHMe)_2CH_2CH_2-$

A careful comparison of the properties of the various derivs. of pulegone and those of α -santolinenone (b) confirms the similarity of these compds. and the structure previously assigned (l. c.). This structure, $Me_2CHCH \begin{array}{c} \diagup CH_2CH_2 \\ \diagdown CH_2CO \end{array} C:CH_2$,

takes into account the facts (1) that (b) gives a NH_2OH deriv. directly and must therefore have a double bond in the α,β -position with respect to the CO. (2) it gives an oxime and must have the double bond in a position which is stable to the action of alkali, as in pulegone, which gives isopulegone oxime instead. (3) The hydroxylamine oxime compd. must have the CO in the nucleus according to Harries' rule so that (b) is a ketone and not an aldehyde. (4) The NH_2OH compd. gives a colorless oxime by oxidation and must have the $NHOH$ group on a primary or secondary C atom, and since it is not eliminated directly it must be outside of the nucleus which is in accordance with the analogous behavior of the same deriv. of pulegone. (5) It does not give the NH_2OH compd. directly; so the C outside of the ring is not tertiary but secondary or primary, which agrees with (4). (a), $C_{10}H_{17}:(NOH)NHOH$, forms transparent, hexagonal prisms, m. 190° with evolution of gas and partial crystn. It m. again about 260° . In the fusion simultaneous oxidation and reduction occur and an amino oxime and a dioxime are formed. The aq. soln. reduces Fehling soln. slightly but the EtOH soln. more energetically. (a) in EtOH + Et_2O with $(CO_2H)_2$ in Et_2O ppts. slowly the oxalate of (a), m. 222° (decompn.). 0.70 g. (a) in 100 cc. of 12% KOH + BzCl sepd. the dibenzoyl derivative of (a), $C_{24}H_{28}O_4N_2 \cdot 0.5H_2O$, m. $127-9^\circ$ or, anhydrous, 134° ; sapond. by alkalis to give BzOH + (a). α -Santolinenoneaminooxime (c), $H_2NC_{10}H_{17}NOH$, and α -santolinenone dioxime (d), were obtained on heating (a). They were sepd. by treating with cold EtOH from which (d) seps. On concg. the EtOH soln. and treating with Et_2O (c) was sepd. as large crystals, m. 155° ; it forms a hydrochloride, m. 246° (decompn.), for which analytical data lie between those of the mono- and dihydrochloride. (d), $C_{10}H_{16}(NOH)_2$, m. 260° ; its dibenzoyl derivative, m. $157-8^\circ$. (a) in alc. reduces HgO and gives a dioxime identical with (d). It was thought that on treating (a) with acids the ketone or oxime would be readily obtained but the result was not so simple. 5 g. (a) + 50 cc. concd. HCl + 50 cc. H_2O were heated for 14 hrs. under a reflux condenser; the yellow soln. was concd. *in vacuo*, dissolved in Et_2O , treated with Na_2CO_3 , distd. with steam and the residue extd. with Et_2O , which sepd. prismatic crystals of what was found to be α -santolinenonenitrileimine (e), $C_{10}H_{16}N_2$. It instantly reduced Fehling soln., $NH_3 \cdot Ag_2O$ or HgO soln. in the cold. With Na phosphomolybdate it gives a green and shortly afterwards a blue coloration, which is obtained at once in the presence of NH_3 . When (e) was sepd. by treating the soln., concd. *in vacuo*, with a little H_2O , then treated with Na_2CO_3 and extd. with Et_2O , the last Et_2O exts. concd. and taken up with H_2O , α -santolinenoneiminoxime, $C_{10}H_{18}ON_2$, sepd. as small granules or cruciform crystals, m. $169-72^\circ$, reduces Fehling soln. with difficulty, but readily even in the cold if previously treated with HCl; it is not pptd. with Na phosphomolybdate nor does it give any color, but on adding NH_3 a blue coloration is produced. Its reducing powers are weaker than those of the hydroxylamine oxime or of the anhydrohydroxylamine oxime. When 3 g. (a) were heated 6 hrs. with 1 cc. of 50% HCl α -santolinenoneimine, $O:C_{10}H_{17}:NH$, was obtained as a yellow oil which in aq. soln. showed the characteristic odor of nicotine bases. Gentle warm-

ing of the cold satd. soln. even by the hand causes the liquid to become milky, the base sepg. in colorless oily drops having a d. almost the same as that of the soln. As the soln. cools the turbidity disappears and the drops redissolve. It reduces AgNO_3 , HgO and with difficulty hot Fehling soln. and shows many characteristic alkaloid reactions. The base formed by the action of acids on pulegonehydroxylamine shows similar properties.

E. J. WITZEMANN.

Pentahydroxyflavone. G. BARGELLINI AND LYDIA MONTI. Univ. Rome. *Gazz. chim. ital.* 45, I, 64-9(1915).—By a method analogous to that used in the transformation of chalcones into hydrochalcones (*C. A.* 9, 447) B. and M. have tried to convert flavones into flavanones. But neither in the case of 1,3,3',4',5'-pentahydroxyflavone (II), which was mainly studied, nor with the other flavones was a positive result obtained. It is hoped that (II) may be converted into myricetin, the flavanol corresponding to (II), and its synthesis will be attempted later on by the use of trimethylgallic aldehyde. (II) was obtained by demethylating 2,3,6,3',4',5'-hexamethoxybenzoylacetophenone (I) and by the loss of 1 H_2O from the corresponding hexa-HO deriv. 2,4,6-(MeO) $_3$ - $\text{C}_6\text{H}_3\text{Ac}$ + Me trimethylgallate with metallic Na at 140° , gave (I), $\text{C}_{21}\text{H}_{24}\text{O}_8$, as white

crystals from dil. EtOH, m. $102-4^\circ$, after drying at 100° m. $136-8^\circ$, sol. in EtOH, C_6H_6 and CHCl_3 , gives a red coloration with FeCl_3 and gives (II) on warming with strong HI. (II), purified by way of its Ac deriv., was obtained as a cryst. powder from dil. EtOH, contains H_2O of crystn., which is only lost completely at 110° , blackens and decomps. above 270° , insol. in C_6H_6 , acetone, Et_2O , etc., gives an orange-red soln. in NaOH, a yellow soln. in concd. H_2SO_4 , a green-brown color in FeCl_3 soln., apparently gives the tri-Me ether with $\text{MeI} + \text{KOH}$. The pentaacetyl derivative, $\text{C}_{24}\text{H}_{20}\text{O}_{12}$, sepd. as white needles from EtOH, m. $216-8^\circ$, sol. in EtOH and C_6H_6 . E. J. WITZEMANN.

Constitution and synthesis of scutellarein. G. BARGELLINI. Univ. Rome. *Gazz. chim. ital.* 45, I, 69-80(1915).—Scutellarein occurs in plants of the genera *Scutellaria*, *Galeopsis* and *Teucrium*. Goldschmidt and Zerner (*C. A.* 5, 1750) found it as $\text{C}_{21}\text{H}_{18}\text{O}_{12}$, yellow needles which in 30-40% H_2SO_4 give by hydrolysis scutellarein (a), $\text{C}_{18}\text{H}_{16}\text{O}_8$, and glucuronic acid. (a) gives yellow crystals m. about 300° (decompn.) which, heated with KOH at 200° , gives $p\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ and a phenol that gives the pine reaction for phloroglucinol. Thus (a) seems to be 1,3,4-trihydroxyflavanol and since it is not identical with camphorol G. thought that (a) might be (I). G. and Z. were able to prep. the tetra-Ac (m. $235-7^\circ$), tri-Me ether (m. $189-90^\circ$), the acetyl tri-Me ether (m. $167-9^\circ$) and the tetra-Me ether (m. $158-60^\circ$) derivs. Heating (a) with 12% KOH gave $p\text{-HOC}_6\text{H}_4\text{Ac}$ almost quant. which shows (a) to be a flavone. The poly-OH compd. formed at the same time was thought to be 1,2,3,5- $\text{C}_6\text{H}_3(\text{OH})_4$ (b) so that (a) is thus (II) or (III). (b) gives the pine chip reaction of phloroglucinol.

(a) gives a green color with $\text{Ba}(\text{OH})_2$. B. observed that 2,5,1,3- $\text{C}_6\text{H}_3(\text{OH})_3(\text{OMe})_2$ gives a green color with alks. and became interested in the synthesis of (a). By apply-

ing v. Kostanecki's synthesis of flavones to 2,3,4,6-(MeO)₄C₆HAc and Me anisate plus Na, B. obtained 2,3,4,6,4'-pentamethoxybenzoylacetophenone (c) which was demethylated with HI and by loss of H₂O gave the tetrahydroxyflavone which, acetylated, purified as such and, sapond., gave the flavone identical with (a). The tetra-Ac derivs. of the natural and synthetic products are identical. B. tried to obtain the derivs. in pure form but could not do so owing to the lack of material. It was shown that (a) is either (II) or (III). It is possible that both are formed but only one has been isolated.

(III)

(IV)

B. oxidized apigenin (1,3,4'-trihydroxyflavone) with CrO₃ (cf. Nierenstein-Wheldale, C. A. 6, 751) and obtained a red substance, probably an oxidation product (IV) (analogous to chryson and quercetone obtained by N. and W. from chrysin and quercetin) which he hopes to convert by acetylation to the tetrahydroxyflavone deriv. and thus det. whether (II) or (III) represent the constitution of (a). 5 g. 2,3,4,6-(MeO)₄C₆HAc + 10 g. Me anisate + 1 g. Na gradually were heated at 125-35° 15-30 mins. The product in H₂O acid with AcOH was extd. with aq. NaOH (15 g. per 400 cc.), CO₂ was passed through and a pasty red-yellow ppt. was formed. This, boiled in EtOH with animal charcoal, gave on adding H₂O, 4 g. of pure yellow crystals of (c), m. 104-6°, insol. in H₂O, sol. in C₆H₆, acetone and EtOH, gives a red color with alc. FeCl₃. 2 g. (c) + 20-25 cc. HI (d. 1.7) heated under a condenser seps. the flavone. After 2 hrs. the whole is thrown into NaHSO₃, filtered and washed. (a) thus obtained could not be recrystd. from organic solvents. 1 g. crude (a) + 2 g. NaOAc + 10 g. Ac₂O boiled 2 hrs. sepd. the tetraacetyl derivative of (a), recrystd. from AcEt as white needles, m. 235-7°. 1 g. of this sapond. by heating with 10 cc. HI sepd. the flavone which, after treating as before, was dissolved in MeOH and gave some impure yellow crystals. Better results were obtained by dissolving in AcOH and pptg. with H₂SO₄ as the sulfate which, washed on the filter, was decompd. and, recrystd. from MeOH, gave yellow laminas of (a). The tetrahydroxyflavone thus obtained showed all the characteristics of natural scutellarein as previously described by Molisch, G. and G. and Z. The sulfate is C₁₆H₁₀O₈.H₂SO₄. The formation of these salts is characteristic of colored org. substances and especially flavones containing 2 adjacent OH's in the same C₆H₄ nucleus.

E. J. WITZEMANN.

Derivatives of 1,2,3,5-tetrahydroxybenzene. G. BARGELLINI. Univ. Rome. Gazz. chim. ital. 45, I, 85-90(1915).—In continuing the earlier expts. (C. A. 5, 3806) on the C₆H₂(OH)₄ derivs. B. has prepd. some derivs. of 1,2,3,5-C₆H₂(OH)₄ in the hope that compds. of the apiole type could be obtained from these. The latter were not obtained but B. thinks compds. similar to those obtained may still occur in plants. 1,2,3,5-C₆H₂(OMe)₄ (a) (b. 270-1°, m. 47°) was obtained by converting 1,2,3-C₆H₂(OMe)₃ into dimethoxyquinone and reducing to dimethoxyquinol under conditions previously described (l. c.). This with PrCl + AlCl₃ in CS₂ gives both 2,3,4,6-tetrahydroxypropiophenone trimethyl ether (b), C₁₂H₁₆O₈, yellow prismatic crystals, m. 124-6°, sol. in alkalis, insoluble in H₂O, sol. in EtOH and C₆H₆, gives a yellow-brown color with FeCl₃, sol. in concd. H₂SO₄ with yellow coloration and warming gives a dark violet color; and 2,3,4,6-tetramethoxypropiophenone, C₁₂H₁₆O₈, white crystals, m. 55-6°, is formed from the preceding with Me₂SO₄, insol. in H₂O and alkalis, sol. in org. solvents, sol. in concd. H₂SO₄ with yellow, and, on warming, dark violet

coloration. The *acetyl derivative* of (b) was obtained as white needles, m. 73-4°. (a) in CS₂ with BzCl + AlCl₃ gives both 2,3,4,6-tetrahydroxybenzophenone trimethyl ether (c), C₁₈H₁₈O₈, and 2,3,4,6-tetramethoxybenzophenone (d), C₁₇H₁₈O₆. (c) was obtained as needles from EtOH or ligroin, m. 87-9°, sol. in alkalis, gives a red-brown coloration with FeCl₃, a red, then green color with concd. H₂SO₄, which on warming is first green, then dark violet. (d) sepd. from dil. EtOH as white crystals, m. 125-6°, insol. in alkalis, concd. H₂SO₄ gives a red, then yellow soln., but on warming it is dark green. The *acetyl derivative* of (c), C₁₈H₁₈O₈, sepd. from EtOH as crystals, m. 130-2°.

E. J. WITZEMANN.

Coumarin. G. BARGELLINI AND LYDIA MONTI. Univ. Rome. *Gazz. chim. ital.* 45, I, 90-8(1915).—It is known that when persulfate acts on PhOH in alk. soln. in the cold a new OH enters the ring to give *p*-C₆H₄(OH)₂, but if the *p*-position is occupied it goes into the adjoining position. The latter was observed a number of times by B. and Aureli (*C. A.* 6, 992) with peonol. B. and M. have now studied the action of persulfates on coumarin in which the OH is combined with the CO₂H, but since in alk. soln. the lactone is opened the action is really on the alkali salt of *o*-hydroxycinnamic acid. Thus coumarin should give 2,5-(HO)₂C₆H₃CH:CHCO₂H or the corresponding coumarin (a). In the same conditions 4-methoxycoumarin (b) gives 4-methoxy-5-hydroxycoumarin (c), which is identical with the monomethyl ether of aesculetin (d), m. 184°, which was obtained by Tiemann and Will (*Ber.* 15, 2075(1882)) by partial methylation of (d). Scopoletin is also a monomethyl ether of (d) but since it is not identical with (c) it must be 4-hydroxy-5-methoxycoumarin. 5 g. coumarin in 15 cc. of 40% KOH dild. to 150 cc. + 1 g. FeSO₄ in H₂O and 15 g. powdered K₂S₂O₈ gives a red-brown soln. after 24 hrs. at room temp., which, acidified with dil. H₂SO₄, extd. with Et₂O, etc., gave (a) as yellowish needles from HCl-H₂O, m. 248-50° (decompn.); *acetyl derivative*, C₁₁H₈O₄, white needles from dil. EtOH, m. 147-8°. 1 g. (a) + 0.4 g. KOH in 25 cc. MeOH + 3 g. MeI heated for 2 hrs. gave, when thrown into H₂O, 5-methoxycoumarin, white flat needles, m. 102-3°. Umbelliferone + MeI + KOH as above gave (b), leaves from H₂O or dil. EtOH, m. 114-5°. When oxidized with persulfate, etc., as above, (b) gives (c) as yellow-white crystals from H₂O, m. 184°; the aq. soln. gives no coloration with FeCl₃; the *acetyl derivative* of (c), C₁₁H₁₀O₆, was obtained as white needles from dil. EtOH, m. 164-5°. (c) treated with MeI + KOH gave 4,5-dimethoxycoumarin as white needles, m. 142-3°.

E. J. WITZEMANN.

The constitution of phenyl-*m*-nitroindone. M. BAKUNIN AND T. ANGRISANI. Univ. Naples. *Rend. accad. sci. fis. mat. Napoli* 20, 181-4(1915); *Gazz. chim. ital.* 45, I, 160-4(1915).—Phenyl-*m*-nitroindone (a), m. 118°, was prepared from phenyl-*m*-nitrocinnamic acid, m. 195°, by the action of P₂O₅ on its CHCl₃ soln. The constitution was detd. as before (*C. A.* 7, 78) by treating it with O₃ in CHCl₃ (free from EtOH). A Siemens-Halske ozonizer (type O.T.W.3) and O₂ containing 7% O₃ were used. 3 g. (a) were used and the rose soln. became pale yellow. The soln. was turbid owing to the presence of a small amt. of a substance that m. above 300°, and which is insol. in ordinary solvents and is not changed by H₂O or Na₂CO₃. The residue from the CHCl₃ soln. gave the calcd. amt. of a syrupy mass. This, boiled with Na₂CO₃, dissolved in part and in the insol. part the substance that m. above 300° was found. The soda soln. acidified with HCl, evapd. and extd. with petr. ether, gave BzOH, m. 121°. The C₆H₅ ext. gave crystals from H₂O, m. 133-4°, which were shown to be 2,4-OHC(O₂N)-C₆H₃CO₂H (b) by oxidizing with KMnO₄ to 4-nitrophthalic acid, m. 161°. The BzOH and (b) are evidently produced by the hydrolysis of the ozonide of the indone (I) and

(a) has the constitution (II). In order to isolate the products of ozonization the product was treated with boiling H_2O . Both $BzOH$ and (b) were sepd. The compd. that m. above 300° was isolated (comp. = (a) + H_2O_2), as well as a 2nd more sol. compound, needles, m. 214° (C 57.06, and H 3.3%, which correspond closely with the comp. of the perozonide of (a)). Another compd., amorphous powder, m. 180° (not sharp), was isolated of which the comp. corresponded to the ozonide of (a) or (I). The ozonide and perozonide were not satisfactorily isolated. E. J. WITZEMANN.

The constitution of phenyl-*p*-nitroindone. M. BAKUNIN AND A. KOSSINOVA. Univ. Naples. *Rend. accad. sci. fis. mat. Napoli* 20, 178-81 (1914); *Gazz. chim. ital.* 45, I, 164-7 (1915).—Phenyl-*p*-nitroindone (a), prepd. from phenyl-*p*-nitrocinnamic acid, m. 147° , by the action of P_2O_5 in $CHCl_3$, rhomboidal red laminas, m. 217° . Its small solubility in solvents made mol. wt. detns. impossible. The presence of the double bond was detd. as before by prepg. the ozonide. 30 g. (a) suspended in $CHCl_3$, treated 30 hrs. with O_3 and evapd., gave a syrupy substance. By treating again with $CHCl_3$, 15 g. of an easily sol. substance was sepd. which proved to be 2,5-OHC(O_2N) C_6H_4 CHO (b), m. 161° (Wegscheider, *Monatsh.* 24, 805), as was shown by oxidizing it in 20% Na_2CO_3 with 0.66 mol. of 6% $KMnO_4$ to 4-nitrophthalic acid. Another portion of the ozonization product contained $BzOH$ which was sepd. with petr. ether and then with C_6H_6 . More (b) was isolated from the part less sol. in C_6H_6 . The portion of the syrupy residue more sol. in C_6H_6 contained a compd. of the comp. of the ozonide as was shown by analyses and by boiling a short time with H_2O which gave a mixt. of $BzOH$ and (b) which were isolated. This ozonide could not be obtained as a solid like that of the *o*-deriv. It was thus shown that (a) is $(5)O_2NC_6H_4(2)CH:CPh.CO$, which indicates the

manner of its formation. Another portion of the ozonized indone was gently boiled with Na_2CO_3 and gave *p*- $O_2NC_6H_4CO_2H$ and *p*- $O_2NC_6H_4CHO$ (m. 105°), besides the compds. isolated above. E. J. WITZEMANN.

Symmetrical diaminotetrazine. IV. G. PONZIO AND C. GASTALDI. Univ. Sassari. *Gazz. chim. ital.* 54, I, 181-3 (1915).—The prep. of $N:(H_2N)C:N:N.C(NH_2):N$

(a), from aminoguanidine-HCl (b), $CH_2N_4.HCl$, has been described (*C. A.* 8, 80, 2691). The prepn. of (a) by the decompn. of aminoguanidine bicarbonate (c), $CH_2N_4.H_2CO_3$, by heat is described. 1 mol. (c) = $(H_2N)_2C:NNH_2 + H_2O + CO_2$. 2 mols. $C(NH_2)_2:NNH_2$ give 1 mol. *N-v-dihydro-C-diaminotetrazine* (d), $N:C(NH_2).NH.NH.C(NH_2):N$,

and (d) by the action of atm. O is oxidized to (a). For this purpose (b) was mixed with excess $NaHCO_3$ in a mortar and warmed in a dish on the H_2O bath. After 1 hr. the product was treated with dil. AcOH and on the addition of HNO_3 the nitrate of (a), $C_2H_4N_6.HNO_3.0.5H_2O$, seps., m. $180-2^\circ$. By adding NH_3 the free base (a), m. $204-5^\circ$, was obtained. The yield of (a) is small because most of the aminoguanidine (e) remains unchanged. When the bicarbonate of (e) was heated at 100° the yield was less than when (b) + $NaHCO_3$ were used. A cold concd. soln. of (a) treated with HBr gives the *hydrobromide*, yellow laminas, decomp. in the air, explodes at 120° . A concd. aq. soln. of $KHCO_3$ treated with a soln. of a salt of (a) ppts. the *bicarbonate* of (a), $C_2H_4N_6.H_2CO_3$, yellow laminas, decomp. 100° to give (a) + CO_2 . It is better obtained by passing CO_2 into a cold aq. soln. of (a).

E. J. WITZEMANN.

Action of nitroso derivatives on unsaturated compounds. LUIGI ALESSANDRI. Florence. *Atti accad. Lincei* 24, I, 62-7 (1915).—In an earlier study (Angeli, *et al.*, *C. A.* 4, 2457) of the action of $PhNO$ on unsatd. compds. its action on saffrole was studied. $CH_2O_2C_6H_4CH:CH.CH:N(:O)Ph$ (a) was obtained. This is the *N-Ph*

ether of $\text{CH}_2\text{O}_3\text{C}_6\text{H}_5\text{CH}:\text{CH}:\text{CH}:\text{NOH}$ which is formed by the action of NH_2OH on safrole. From this oxime piperonalacrolein is easily obtained and from this + PhNHOH the compd. (a) was likewise obtained. It is thought that dimol. PhNO acts on safrole to give the addition compd. $\text{CH}_2\text{O}_3\text{C}_6\text{H}_5\text{CHCH}:\text{CH}:\text{N}:(\text{O})\text{Ph}$ which then gives (a) +

PhNHOH and the latter reacts with PhNO to give azoxybenzene which was found in the products. In extending the expts. in order to det. how general the reaction is A. treated estragole, myristicin and methyleugenol with PhNO and obtained 3 yellow products that m. 165° , 180° and 154° , resp., the structure of which is like (a); they decomp. in the sunlight. Apiole (from parsley) treated with PhNO similarly gives a yellow compd., m. 137° (decompn.), unstable to KMnO_4 and contains no N. This deriv. reacts with NH_2OH to give a compd. (b), $\text{C}_{12}\text{H}_{12}\text{NO}_5$, m. 172° . The product, m. 137° , may be apiolacrolein, $\text{CH}_2\text{O}_3(\text{MeO})_2\text{C}_6\text{HCH}:\text{CHCHO}$, of which the oxime would correspond to (b). The facts that the acid $\text{CH}_2\text{O}_3(\text{MeO})_2\text{C}_6\text{HCH}:\text{CHCO}_2\text{H}$ was identified and that a colorless compd. m. about 100° , which was probably apiolaldehyde, was extd. as the bisulfite compd., lend support to this view. The explanation is further confirmed by expts. on aromatic derivs. with propenyl side chains. Asarone + PhNO give a cryst. yellow compd. (c) similar in every way to the allyl derivs. (l. c.) and with KMnO_4 it evolves PhNO . (c) seps. with solvent of crystn. which it loses completely at 125° and shows the comp. $\text{C}_{11}\text{H}_{11}\text{NO}_4$. (c) treated with NH_2OH gives a colorless oxime, m. 137° , probably identical with asarylaldoxime (Fabinyi, *Z. physik. Chem.* 12, 578). Likewise (c) hydrolyzed with dil. acid gave a product, m. $112-3^\circ$, having the properties of asrylic aldehyde. The latter reacts with PhNHOH to give back (c). Thus (c) is the N-Ph ether of asarylaldoxime, $(\text{MeO})_2\text{C}_6\text{H}_5\text{CH}:\text{N}:(\text{O})\text{Ph}$. Among the secondary products asrylic aldehyde and azoxybenzene were found. Fabinyi found a similar reaction when treating asarone with alkyl nitrite + HCl . The final product was in all cases either asarylaldoxime-HCl or asaryl aldehyde and in the latter case the N_2O evolved corresponded to the azoxybenzene found by A. in the prepn. of (c). A. believes that the PhNO may reduce some of the allyl chain to the propenyl group and thus gives rise to other side reactions and it was for this reason in part that in the case of isosafrole the N-Ph ether of piperonal could not be isolated. From the above it appears that the reaction is not always simple and that the variable yield is due to these causes. The unsuccessful expts. with rubber (l. c.) were taken up again. Powdered rubber was placed in C_6H_6 with PhNO and when the mixture became rose-yellow the liquid, sepd. by decantation and dild. with ligroin, gave amorphous yellow flocks which were taken up with ligroin and gave a friable mass, sol. in CHCl_3 , less sol. in C_6H_6 and very little sol. in CS_2 , ligroin and Et_2O , insol. in H_2O , softens with decompn. $135-40^\circ$. The product, pptd. several times from ligroin with CHCl_3 , had a comp. equiv. to that calcd. for the condensation of 1 mol. rubber with 2 mols. PhNO . It also evolved PhNO and isonitrile with KMnO_4 but seemed insensible to light. Further details on all of the above will be published later. E. J. WITZEMANN.

The constitution of triphenylaminoethyl alcohol obtained by the action of light. LYDIA MONTI. Univ. Rome. *Atti accad. Lincei* 24, I, 143-6 (1915); *Gazz. chim. ital.* 45, I, 359-62 (1915).—Paternò recently described a compd. $\text{C}_{20}\text{H}_{19}\text{ON}$ (*C. A.* 8, 2687) obtained by the action of light on a mixture of BzPh and PhCH_2NH_2 to which, on the basis of analogy, he assigned the constitution of a triphenylaminoethyl alcohol (a), $\text{Ph}(\text{NH}_2)\text{CHCPh}_2\text{OH}$. The correctness of this supposition was proved by treating some of it with NaNO_2 and AcOH to obtain the known anhydride of triphenylglycol (b), $\text{PhCH}:\text{CPh}_2\text{O}$. 2 g. (a) in 25 cc. AcOH treated in the cold with 2 g. NaNO_2 in a little

H₂O evolved gas and sepd. yellowish white crystals of (b), recrystg. from EtOH as white needles, m. 134-6°. The compd. (b) was further identified by prepg. the *acetyl derivative*, m. 101-3°. Sometimes in treating (a) with NaNO₂ + AcOH other products, m. 217-9° and 232-3°, were formed but were not studied further. Presumably the first is the *monoacetyl derivative* of (a) obtained by Paternò by the action of PhBz on PhCH₂OAc in the sunlight. The 2nd is probably a hydrocarbon obtained by Biltz (*Ber.* 26, 1957; *Ann.* 296, 242).

E. J. WITZEMANN.

Action of hydrochloric acid gas upon carbohydrates. XV. THEODOR PANZER. *Z. physiol. Chem.* 94, 10-72(1915).—A study was made of the action of HCl gas upon finely pulverized galactose, grape sugar, levulose, sucrose, maltose, lactose, starch, sol. starch and dextrin. All these seem to take up HCl and bind it chemically. By the action of H₂O upon these chem. compds. the bound Cl is easily and completely given off as HCl. The amts. of HCl taken up by the various carbohydrates are very different. In levulose and cane sugar there is a deep-seated decompn. which leads to carbonization. In the case of the other carbohydrates, aldoses and their di- and polysaccharides, the reaction seems to be comparatively simple. *In vacuo* the reaction products give up a part of the bound Cl as HCl, but a part is retained. Besides the HCl, H₂O is also probably given off *in vacuo*. This might result from the action of the HCl upon the HO groups. This needs proof, however, for oxidation processes may also be produced by the action of the HCl in the presence of O, and volatile org. or Cl-contg. compds. might then be given off *in vacuo*.

G. M. MEYER.

Action of ultraviolet rays on glycerol. HENRY AND RANC. *Giorn. farm. chim.* 62, 73(1913).—Ultraviolet rays cause the decompn. of glycerol with production of CH₂O and traces of other substances of an aldehyde nature. The decompn. takes place more readily in the presence of H₂O.

H. S. PAINE.

Simplified representation of cyclic compounds. ENRIQUE V. ZAPPI. *Anales soc. quim. Argentina* 2, 119-23(1914).—Bonds are represented by a succession of lines which limit a polygon, the number of sides of the latter being equal to the number of elements which form the ring. C is not indicated and is considered to be present at each angle of the polygon; if the compd. is heterocyclic, the extraneous elements are indicated at the proper position in the ring. Valences which are not indicated as being satisfied mutually or by substitution are considered to be satisfied by H without further representation, the valences of S and O being 2, and N and C 3 and 4, resp. in cyclic compds. Substitutions are indicated at the side of the proper angle of the polygon. When the angles of the figure become less prominent in the case of more complicated cyclic compds. certain elements may be suppressed and their existence

indicated by short lines in simpler figures, thus

cycloheptene and

camphor. If another element is present in place of C it is

sufficient to intercalate it without adding a line, thus tropine and tropidine may be

represented, resp. by

—OH and

The following examples of simplified representation will serve to illustrate the above system:

Mercury glycerophosphate. G. PRUNIER. *Boll. chim. farm.* 53, 697(1914).—Mercury glycerophosphate was prepd. by the reaction of a soln. of Hg nitrate containing HNO_3 with a 50% soln. of Na glycerophosphate. When HgNO_3 was employed a Hg' glycerophosphate containing 70.07% Hg and 5.40% P was obtained. A Hg' glycerophosphate with 54.29% Hg and 8.21% P was produced from $\text{Hg}(\text{NO}_3)_2$. Hg' and Hg'' glycerophosphates have the following formulas, resp.: $(\text{HgO})_2\text{P}(\text{:O})\text{OCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$; Hg  $\text{P}(\text{:O})\text{OCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$.

Electrolytic reduction of the quinoline alkaloids. J. A. W. BREDENBERG. *Svensk Kem. Tidskrift* 27, 5-8(1915).—An elec. current passed through H_2SO_4 solns. of the cinchona alkaloids (quinine, cinchonine, and cinchonidine) causes them to take up 2 mols. H per mol. alkaloid. B. notes in the case of cinchonine that part of the product formed in this reaction is cryst. The cryst. part has the same comp. as the amorphous part. The substance after reduction is sol. in Et_2O , by which property it is removed from the reaction mixt. The moisture is removed with fused KOH and the Et_2O distd., leaving a semi-liquid residue in which crystals formed on standing. The crystals were insol. in Et_2O and by this solvent completely sepd. from the amorphous part. Cryst. yield, 50%; m. p. 135° . B. designates it as dihydrodesoxycinchonine.

A. R. ROSE.

Chromoisomeric salts of acetoacetic ester-like phenol and enol derivatives. A. HANTZSCH. *Ber.* 48, 785-97(1915); cf. *C. A.* 9, 2095.—Sym. compds., $(\text{RCO})_2\text{CH}_2$, never form chromoisomeric enol salts while unsym. compds., $\text{RCOCH}_2\text{COR}'$, often do, forming structural isomers, $\text{RC}(\text{OM}) : \text{CHCOR}'$ and $\text{RCOCH} : \text{C}(\text{OM})\text{R}'$, which with residual affinities can be represented as "conjugated" enol salts with 6-membered rings, (I) and (II). The existence of such chromoisomers can be shown only if the

absorption of the most strongly absorbing series, at least, extends to the visible spectrum, giving a colorless form absorbing only in the ultraviolet, and a yellow form absorbing in the violet, or, if the absorption of the acid ion is sufficiently great, a more weakly absorbing yellow and a more strongly absorbing red form. In the case of a compd. like succinylsuccinic ester (a), there exist colorless and yellow monometallic and yellow and red dimetallic salts. *p*-Dihydroxy-*p*-phthalic (b) and dihydroxy-quinonedicarboxylic ester (c) likewise form yellow and red dimetallic salts; these compds. contain the structurally isomeric complexes $(\text{MO})\text{C} : \text{C} \cdot \text{CO} \cdot \text{OR}$ and $\text{O} : \text{C} \cdot \text{C} : \text{C} : \text{C} \cdot (\text{OM}) \cdot \text{OR}$ and may be designated as enol and ethoxyenol or benzoid (phenol) and quinoid (enol) salts, resp., the former being the more weakly absorbing forms. They should form 3 series of salts: dibenzoid, least absorbing or yellow; benzoid-quinoid, with medium absorption or orange; diquinoid, most strongly absorbing or red. In general, however, only the yellow and red forms have been isolated. When the chromo-

isomerism cannot be proved by direct isolation of 2 forms, it can be shown indirectly by taking advantage of the fact that all alkali and alk. earth salts of a colored acid of unchangeable constitution are "monochromic" in the solid state and give almost isospectric solns. (C. A. 8, 10); if, therefore, an acid gives alkali or alk. earth salts differing in color, this affords proof of chromoisomerism; another indirect proof is afforded if the hydrate of such an alkali or alk. earth salt differs in color from the corresponding alcoholate or other solvate; again, if the anhydrous salt differs from its solvate; and, finally, if the solid salt differs from its solns. in color. *Salts of (a)* (cf. Herrmann, *Ann.* 211, 327(1882)). The pure monoalkali salts are pptd. from an Et_2O soln. of (a) by barely 1 atom, the dialkali salts by a good 2 atoms of alc. alkali; they must be filtered and dried as quickly as possible, protected from the air. The much more stable alk. earth salts are obtained by shaking the freshly pptd. alkali salts, still in Et_2O - EtOH suspension, with the aq. alk. earth chlorides at 0° . All the monoalkali salts are colorless (Herrmann describes them as pink) but dissolve in H_2O and alc. with intense yellow color. *Dilithium salts: dialcoholate*, crimson, loses its alc. at 90° ; *dihydrate*, yellow; *anhydrous*, brick-red. *Barium: dihydrate*, light crimson; *anhydrous*, yellow. *Calcium: dihydrate*, yellow; *anhydrous*, yellow. *Magnesium: dihydrate*, red; *anhydrous*, yellow. *Salts of (b)* (obtained by Herrmann only in cinnabar-red forms): *Dilithium: dialcoholate*, cinnabar-red; *solvent-free*, yellow. *Barium: dihydrate*, red; *anhydrous*, yellow. *Calcium: anhydrous*, red. *Magnesium: dihydrate*, red; *anhydrous*, yellow. The indications in the literature that the salts of the free acid corresponding to (b) are sometimes colored are erroneous; the yellow to brownish colors observed were due to impurities, produced by rapid oxidation of the acid in alk. soln. *Salts of (c)*: Gradual neutralization of (c) gives red solns. of the monometallic salts changing to yellow solns. of the dimetallic salts; in the solid state all the salts of colorless inorg. bases, NH_4Me , NHMe , PhNH_2 , piperidine, NPr_4OH are yellow; those of NMe_3 , NPr_3 , $\text{C}_6\text{H}_5\text{N}$ and PhNMe_2 only when crystd. from H_2O alc. or Et_2O , sepg. from CHCl_3 or C_6H_6 in red solvated form. *Diammonium salt: Trimethylammonium; solvent-free*, yellow; *with 1 C}_6\text{H}_6*, red; *with CHCl}_3*, orange. *Pyridine salt, (c).2.5C}_6\text{H}_5\text{N}*, red, goes over at 60° into the *monopyridine salt, (c).C}_6\text{H}_5\text{N}*, yellow. *Tetramethylammonium salts; yellow*, pptd. in cryst. form by Et_2O from concd. alc. (c) cautiously neutralized with 33% aq. NMe_2OH ; on long standing under the liquid from which it is pptd. or after a few sec. under C_6H_6 it goes over into a *red form* which is converted back into the yellow form on warming gently or, slowly, on standing in the air. Both dissolve in H_2O with yellow color and neutral reaction.

CHAS. A. ROULLER.

Resolution of the phenylglyceric acid melting at 141° into its optically active components. C. N. RIBBER. Drontheim. *Ber.* 48, 823-31(1915).— $\text{PhCH:CHCO}_2\text{Me}$ is obtained in 97% yield from 20 g. acid in 130 cc. H_2O neutralized with solid KOH , shaken 2 hrs. with 40 cc. Me_2SO_4 (which has been washed with H_2O to remove free H_2SO_4), poured off from the aq. liquid, treated with H_2O and heated 0.5 hr. on the H_2O bath. From 20 g. of the ester in 1500 cc. alc. treated at -40° in the course of 4 hrs. with 24 g. KMnO_4 in 800 cc. H_2O is obtained 15 g. inactive phenylglyceric acid, m. 141° . To 6.0 g. morphine in 700 cc. boiling acetone is added 7.3 g. of the acid in 200 cc. acetone and the soln. concd. *in vacuo* over H_2SO_4 to 0.5 its vol.; the cryst. warts (8.8 g.) which gradually sep. are dissolved in dil. H_2SO_4 , extd. with 25 vols. Et_2O , dried with Na_2SO_4 and evapd.; the resulting acid (3.4 g.) is shaken several hrs. at 20° with 22 parts H_2O , whereby the inactive portion dissolves; the residue, after 2 crystns. from H_2O in a vacuum desiccator, gives the pure *l*-acid, while the acetone mother liquors, similarly treated, yield the *d*-acid. The *l*-acid, m. 164° ; $[\alpha]_{\text{D}}^{20}$ -39.63° , -31.42° , -30.90° for the lines D, C, E, resp., (p 3.16% in H_2O); $[\alpha]_{\text{D}}^{20}$ -40.10° (p 1.26% in

H₂O), -30.48° (p 6.28% in 97.7% alc.), -36.43° (p 7.36% in acetone). *d*-Acid, m 164°, [α]_D²⁰ 39.57° (p 3.39% in H₂O). 100 g. H₂O at 20° dissolves 9.00 g. of the *d*- and 4.10 g. of the *d*- or *l*-acid. The crystals of the active acids are monoclinic-sphenoidic with concordant angles but enantiomorphic development, $a : b : c = 2.1875 : 1 : 2.0794$, β 93°53'; observed forms, referred to the *d*-compd., a (100), m (110), m' (110), c (001), d (101), q' (112), r (102), p (102), frequent; q (112), π (212), γ (312), seldom; M (120), uncertain. The inactive crystals, which are very similar in habit, are apparently monoclinic-prismatic. The sp. gr. (1.451) is the same as that of the active forms. The inactive form is therefore probably only apparently racemic, being built up of active parts which, as indicated by the etchings obtained with alc., are larger than mol. in size. This is confirmed by the fact that addition of the active to the inactive acid in increasing amts. produces a continuous rise in the m . p., never a fall. Again, if to a satd. aq. soln. of the inactive form the *d*-acid is added, the concn. of the soln. does not change and it remains inactive, and a soln. satd. with both the *d*- and *l*-acids has the same concn. and sp. gr. as one satd. with the inactive acid. C. A. R.

Condensation of γ -ketonic acids with aldehydes. II. W. BORSCHÉ. Univ. Göttingen. *Ber.* 48, 842-9 (1915); cf. *C. A.* 8, 2164.—Unlike compds. of the type of HOCPh : CHCH₂CO₂H or its Na salt, Na levulinate (*a*) with aromatic aldehydes and Ac₂O does not give MeC : CH.C (: CHR).CO.O, but 2 mols. condense with 2 mols.

of the aldehyde with loss of 3 mols. H₂O. Thus, after several hrs. warming with BzH is obtained (in very poor yield, however) *dimolecular α -acetonylcinnamic anhydride*, [O.CO.C (: CHPh).CH₂.CMe-]₂O, yellow needles from MeOH, m . 108-9°. From

28 g. dry (*a*) heated 12 hrs. on the H₂O bath with 56 g. Ac₂O and 28 g. anisaldehyde, stirred up while still warm with 150 cc. H₂O, kneaded next day with 50 cc. alc., washed repeatedly with cold alc., finally boiled up with 50 cc. alc. and cooled, there is obtained 8.5 g. (the mother liquors yield 1.1 g. more) of the *condensation product*, C₂₂H₂₀O₇, long yellow needles from CHCl₃-EtOH, m . 137-8°; 6 g. boiled with 6 g. soda in 80 cc. alc. and 100 cc. H₂O until a clear soln. results and heated 15 min. longer on the H₂O bath gives 3.7 g. α -anisallevalulinic acid (Thiele, *Ann.* 319, 180 (1901)) and 2.2 g. of its Et ester whose *semicarbazone*, leaflets from AcOH-H₂O, m . 203-4°. From piperonal and 28 g. (*a*) is obtained 10-1 g. of the *compound* C₂₂H₂₂O₈, orange-yellow needles from CHCl₃-EtOH, m . 187°; 6 g. with soda in aq. alc. 0.5 hr. on the H₂O bath yields 2.7 g. α -piperonylidenevalulinic acid, faintly yellow prisms from C₆H₆, m . 125-6°, and 1.8 g. of its *ethyl ester*, yellowish crystals from ligroin, m . 84-5°, whose *semicarbazone*, leaflets from AcOH-H₂O, m . 212° (decompn.). The acid condenses with piperonal in alk. soln., forming α , δ -dipiperonylidenevalulinic acid, pptd. by HCl as a dark yellow amorphous tar which is quickly converted by boiling alc. into a yellowish white cryst. powder, m . 201°; when heated above its m . p., with Ac₂O containing H₂SO₄ etc., it gives 1,4-dipiperonylideneangelicalactone, red-brown needles from PhNO₂, m . 260-1°, sol. in H₂SO₄ with blue-red color; this lactone is better prepd., however, with piperonal and Ac₂O from the Na salt of δ -piperonylidenevalulinic acid, yellowish crystals from alc., m . 150°, which is obtained from 11.6 g. levulinic acid and 15 g. piperonal in 100 cc. alc. warmed a short time with 160 cc. of 5% NaOH. From 28 g. (*a*) with PhCH : CHCHO is obtained 10-2 g. of the *product* C₂₂H₂₀O₈, yellow-red needles from 80 parts alc., m . 166°, b , 166° in small amts. without appreciable decompn.; 6 g. with soda in aq. alc. after 2 hrs. on the H₂O bath gives 4 g. α -cinnamallevalulinic acid, yellowish white needles from 10 parts C₆H₆, m . 154-5°, and 0.7 g. of its *ethyl ester*, flat yellowish spears from ligroin, m . 62-3°. The acid with anisaldehyde or, better, 1-cinnamal-4-anisangelicalactone boiled 12 hrs. with soda in aq. alc. give α -cinnamal- δ -anisallevalulinic acid, light yellow needles from AcOH, m . 233-4°.

CHAS. A. ROULLER.

Cholesterol. XX. Oxidation of cholesterol acetate with chromic acid. A. WINDAUS AND C. RESAU. Innsbruck. *Ber.* 48, 851-7(1915); cf. Mauthner and Suida, *Monatsh.* 17, 594(1896).—Oxycholesterylene (*a*), prepd. by M. and S.'s method, when treated 3 days in Et₂O with Pt sponge and H, yields β -cholestane, indicating that (*a*) is a doubly unsatd. ketone containing the same C skeleton as cholesterol, whereas with Na in boiling alc. it takes up 4 atoms H, forming a new alc., *pseudocholesterol* (*b*), C₂₇H₄₆O, sepg. on the addition of H₂O to turbidity and slow cooling in needles, m. 116°, distinctly adds Br, gives the Liebermann-Burchard cholesterol test but forms no difficultly sol. digitonin addition product; *benzoate*, with BzCl in C₆H₅N, microscopic felted needles from Et₂O-alc., m. 155-6°. Converted in the usual way with PCl₅ into the non-cryst. chloride and reduced with Na and alc., (*b*) gives M.'s pseudocholestene (*C. A.* 2, 659), so that in the formation of (*b*) there must be a rearrangement or shifting of the double bonds. The acid products formed together with β -oxycholesteryl acetate in the oxidation of cholesteryl acetate with CrO₃ were distd. *in vacuo*; CO₂ and AcOH are split off and at 320° (temp. of the air bath) under 25 mm., there passes over a faintly yellow oil crystg. in the receiver; washed in Et₂O with dil. KOH, freed from Et₂O and repeatedly crystd. from alc., it yields a doubly unsatd. *hydrocarbon* (*c*), C₂₆H₄₀, needles, m. 76°, gives in the L.-B. test only a yellow-red color gradually changing to red-brown, $[\alpha]_D^{20}$ -142.9° in C₆H₆, adds only 2 atoms Br in Et₂O-AcOH, forming a *dibromide*, slender needles from acetone, m. 147°. The acid from which (*c*) is derived is therefore probably an acetate of a HO acid with 26 C atoms. With Pt sponge and H in Et₂O, (*c*) yields a mixt. of stereoisomeric *hydrocarbons*, C₂₆H₄₄ (freed from unsatd. compds. by treatment in a little Et₂O or CHCl₃ with Ac₂O and a little H₂SO₄); the satd. compds. sep. from the Et₂O in crystals m. 65°; by repeated crystn. from alc. are obtained long slender needles, m. 80°, and more sol. slender leaflets m. 55-9°; the L.-B. test is negative in both cases. Structural formulas, which, however, are not free of arbitrary assumptions, are given to represent the various changes. **XXI. Coprosterol.** A. WINDAUS and CL. UBRIG. *Ibid* 857-63; continuation of *C. A.* 8, 3442.—Coprostan, obtained from coprosteryl chloride with Na in AmOH, is different from β -cholestane but is identical with Mauthner's pseudocholestane (*C. A.* 4, 1158). W. and C. believe that the isomerism of cholestene and pseudocholestene is due to a shifting of the double bond in the addition and splitting off again of the HCl and that cholestane and β -cholestanol (*d*) differ from pseudocholestane and coprosterol (*e*) only in the arrangement of a H and a Me about the asym. C atom in the EtCHMe- chain. Repetition of Dorée and Gardner's work (*C. A.* 2, 3336) showed that when (*e*) is boiled with Na in AmOH, an equil. is established between (*e*) and pseudocoprosterol (*f*), with over 90% (*f*), and that while (*e*) gives a complex with digitonin (*f*) does not; this affords a means of quant. sepg. the isomers. When 1 mol. each of (*d*), m. 142°, and (*e*), m. 117°, in hot petr. ether are brought together, a *double compound* quickly seps. which crysts. from dil. alc. in long anhydrous needles, m. 152°; digitonin ppts. 0.5 of it, xylene extg. (*d*) from the ppt. and (*e*) from the soln. A sample of Fischer's (*e*), m. 112-6° (*Z. physiol. Chem.* 73, 232(1911)), obtained from human feces, on repeated crystn. from petr. ether yielded a small amt. of difficultly sol. material which was treated with Na and boiling AmOH to convert the (*e*) into (*f*) which is not pptd. by digitonin; the product gave with digitonin a slight ppt. from which xylene extd. pure (*d*), showing that in the human intestine cholesterol can be reduced not only to (*e*) but also to a slight extent to (*d*).

CHAS. A. ROULLER.

Homovanillin. C. HARRIES. Univ. Kiel. *Ber.* 48, 868-9(1915).—The impure oily homovanillin (*a*) described in *C. A.* 9, 1052, was repeatedly fractionated whereupon the part b_{0.24} 105-6° gradually solidified at winter temp. to a hard white cryst. mass; by seeding with this, fractions boiling even considerably lower could be made to cryst.

also; when the crystals were dissolved in warm CS_2 and cooled, a thick reddish oil sepd. on the surface and was mechanically removed; the mother liquors in a freezing mixt. now deposited pure (a) in thick prisms or leaves, m. $50-0.5^\circ$, b. $116-8^\circ$ but always leaves a thick, oily residue. The reddish oil obtained in the crystn. of (a) also gives some pure (a), together with a syrupy residue, on distn. *in vacuo*. While this oil considerably reduces Fehling soln. in the cold, the pure (a) has only moderate reducing power even on warming. Traces of acids or alkalis quickly produce resinification of (a). The derivs. prepd. from pure (a) show the same properties as those previously made from the impure substance, except that the *p*-nitrophenylhydrazone m. 154.5° .

CHAS. A. ROULLER.

Arsenobenzoic acids. A. MICHAELIS. Univ. Rostock. *Ber.* 48, 870-3 (1915). —3 g. $p\text{-HO}_2\text{CC}_6\text{H}_4\text{AsO}_3\text{H}_2$ (*Ann.* 320, 303 (1901)) in 70 cc. boiling H_2O is treated with 2 g. amorphous P and gradually with 12-3 cc. HI (d. 1.96) and heated until the liquid over the crystals which sep. is colorless; the resulting iodide, $\text{HO}_2\text{CC}_6\text{H}_4\text{AsI}_2$, seps. from CHCl_3 in yellow-red needles, m. 153° ; from its soln. in aq. soda, dil. HCl ppts. cryst. $\text{HO}_2\text{CC}_6\text{H}_4\text{AsO}_3\text{H}_2$ which, when dissolved in just the necessary amt. of hot H_2O and heated to boiling with excess of solid H_3PO_3 , yields a yellow-white voluminous ppt. of *p*-arsenobenzoic acid, $(\text{HO}_2\text{CC}_6\text{H}_4\text{As})_2$, decomp. without melting, insol. in H_2O and org. solvents. Disodium salt, prepd. by dissolving the acid in exactly the necessary amt. of dil. NaOH and concg., yellow-brown amorphous powder, sol. in H_2O with neutral reaction, difficultly sol. in dil. NaOH. *o*-Benzarsinic acid, $\text{HO}_2\text{CC}_6\text{H}_4\text{AsO}_3\text{H}_2$, prepd. like the *p*-compd., when reduced with red P and HI, evapd. to dryness, treated in H_2O with dil. NaOH to faint alk. reaction and boiled with H_3PO_3 , gives *o*-arsenobenzoic acid, more deeply yellow than the *p*-compds., melts over the free flame with formation of drops but also partial decompn. and deposition of As. Sodium salt, viscous mass solidifying with difficulty. Both acids, in the form of the Na salts, are very toxic, the *o*- more than the *p*-acid, acting chiefly on the kidneys (albumin and sugar), destroy in small doses the appetite of carniv. and herbivora, cause frequent vomiting in dogs. Sections show severe lesions of the kidneys, numerous small hemorrhagic spots in the mucous membranes of the stomach, and the liver, after long continued action, may show degenerative changes. Of the *o*-acid, amts. corresponding to 1 mg. As per kg. produce albumin and sugar in the urine of rabbits; As can be detected in the decompd. urine.

C. A. R.

New facts on aldehyde-ammonia and chloral-ammonia. OSSIAN ASCHAN. *Ber.* 48, 874-91 (1915); cf. Delépine, *Ann. chim. phys.* [7] 16, 106 (1899), and earlier papers. —A. believes that in aldehyde-ammonia $\text{MeCH}(\text{OH})\text{NH}_3$, which is probably always first formed but cannot be isolated, gives a dimol. form, $\text{MeCH}(\text{OH})\text{NH}_2(\text{OH})\text{CHMeNH}_3$, capable of existence only in soln., and the ordinary solid, trimol. form, $\text{MeCH}(\text{OH})\text{NH}_2(\text{OH})\text{CHMeNH}_2(\text{OH})\text{CHMeNH}_2$ (a), and that the compd. formed when (a) is allowed to stand over H_2SO_4 has the structure $\text{MeCH} : \text{NCHMeNHCHMeNH}_2$ (b). (a) is obtained in 56% yield when 100 g. AcH, cooled with ice-NaCl, is cautiously treated with 200 cc. com. NH_3 (0.201 g. NH_3 per cc.), then with a little Et_2O , allowed to stand 2 hrs. at room temp. and 20-4 hrs. in the ice-chest. So obtained it m. $96-8^\circ$ and after 2 weeks in a closed vessel it still m. $95-7^\circ$ and is hardly yellow after 2 months. In spite of its dissociation it dissolves in 7 parts boiling AcOEt and seps. on cooling in yellowish crystals, m. $94-6^\circ$. It crysts. best from 0.6 part H_2O . In boiling AcH (b. p. const. = 11.8, as detd. with *l*-borneol and Ph_3CO), the mol. wt. of (a) was found to be 30.9-6.5; in freezing H_2O 161-7 immediately after soln., 124-30 after 20-40 hrs. (c). cubes, m. 85° , shows in freezing H_2O the mol. wt. 110-3 immediately after soln., 91.7 after 24 hrs. As the addition of 3 mols. H_2O to (c) in CHCl_3 at once gave (a), probably the same thing occurs when (c) is dissolved in H_2O ; if the above mol. wts. are recalcd.

on this assumption they become 145-62 immediately after soln. and 131.8 in 24 hrs. In freezing C_6H_6 (c) shows a mol. wt. of 153-64; in boiling AcH , 33-6. Alanine was obtained in 8 g. yield from 25 g. AcH dropped into 48 cc. cold concd. NH_3 , allowed to stand 2 hrs. at room temp., treated with 54 g. KCN , then 200 cc. cold HCl (d. 1.19), allowed to stand overnight, filtered, concd. to 0.5 its vol., allowed to stand, again filtered, concd., cooled, treated with a little alc. filtered, dild. with H_2O , boiled with freshly pptd. $Pb(OH)_2$ until free from NH_3 , and decompd. with H_2S . In the prepn. of (a) by the old method (AcH in Et_2O with NH_3 gas) there is formed in about 20% yield a by-product, which A. believes is *dihydroxytriethylidenediimine* (d), $MeCH(NHCHMeOH)_3$, which remains in the Et_2O and after several crystns. carried out as rapidly and at as low a temp. as possible is obtained in leaves, m. 45-7°, decmps. 70-80°, quickly volatilizes at room temp., deposits (a) on long standing in Et_2O (treatment with NH_3 gas does not produce (a) appreciably faster); in closed vessels it slowly turns yellow, the yellow portion now being insol. in Et_2O and the remainder, after evapn. of the Et_2O forming an oil sol. in H_2O , with an amine odor, sol. in acids apparently without decompn. and sepd. by concd. $NaOH$. In freezing C_6H_6 (d) shows a mol. wt. of 180-93; in H_2O 123-42 immediately after soln., 98.3 after 12 hrs. Chloral-ammonia (e), prepd. by Schiff's method (*Ber.* 10, 165(1877)) or from $CCl_3CHO.H_2O$ in 5 parts cold Et_2O with excess of dry NH_3 , m. 69-72°, evolves NH_3 when stirred with cold H_2O and gradually dissolves; mol. wt. in freezing C_6H_6 , 256-350. A. thinks it has the structure $HOCH-(CCl_3)NH_2(OH)CH(CCl_3)NH_2$. When allowed to stand some days over $CaCl_2$ *in vacuo* it passes over into *dihydroxybistrichloroethylideneimine* (f), $HOCH(CCl_3)NHCH-(CCl_3)OH$, m. 51-3°, much more easily sol. in C_6H_6 and H_2O than (e), mol. wt. in freezing C_6H_6 266-316 immediately after soln., 308 after 24 hrs., in freezing H_2O 101-5; in boiling Et_2O 195-285. After 1 month in a closed vessel (f) had become sticky and when stirred with a little H_2O left a solid, m. 67-8°, whose aq. soln. did not smell of NH_3 and was not alk.; mixed with (e) it m. 55-65°. When (f) in cold C_6H_6 is treated with NH_3 and evapd. it gives (f).

CHAS. A. ROULLER.

Use of iodine as a dehydrating and condensing agent. HAROLD HIBBERT. *J. Am. Chem. Soc.* 37, 1748-63(1915).—When heated with small amts. of I, alcs. are readily dehydrated, the ease of dehydration diminishing, however, in the order: tertiary, secondary, primary alc. Possibly, just as $2 KOH + I_2 = KOI + KI + H_2O$, so here, too, alkyl iodides and hypiodites are formed which dissociate to a greater or less extent at or below their b. p. into unsatd. hydrocarbons and HI and HIO, the 2 acids regenerating I, or the iodide and hypiodite may react directly with each other: $RI + ROI = ROR + I_2$. Thus, 60 g. $EtCMe_2OH$ and 0.14 g. I heated 24 hrs. on the H_2O bath in a distg. flask yielded 27 g. $MeCH:CMe_2$, b. 35-9°; 5 g. pinacol and 0.012 g. I at 140° gave 3 g. $(CH_2:CMe)_2$, b. 69-72° (from pinacol hydrate only very poor yields were obtained); 27 g. cyclohexanol with 0.54 g. I in 60 hrs. at 170-5° yielded 21 g. distillate from which was isolated 7-8 g. pure tetrahydrobenzene, b. 82-4°. $AcCH_3CMe_2OH$ and 0.01% of its wt. of I gives 98% of crude $AcCH:CMe_2$ (a), b. 80-130° (the method can be applied to mixts. of acetone and $AcCH_3CMe_2OH$, the greater part of the former distg. over below 80°). In the prepn. of (a), there is always obtained a lower boiling product (b. 80-125°), whose b. p. gradually rises on repeated distn. and the substance is finally converted completely into (a); it is probably the isomeric $AcCH_3CMe:CH_2$. While paracetaldol and acetaldol on slow distn. yield 55 and 49%, resp., of crotonaldehyde (b), addition of a little I (0.1-0.05%) increases the yield to 82 and 80%, resp. A small quantity of H_2O (0.5 g. to 100 g.) appreciably lowers the b. p. of (b) (102-4°), 2.5 g. distg. over below 98° and 30.5 g. at 98-102°. When acetaldol is used in its prepn. there is always obtained a fraction, b. 65-96°, which after careful drying invariably decmps. on distn., yielding (b) and AcH ; this

may possibly be a compd. of the 2 aldehydes of the type $\text{MeCH:CHCH} \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} \text{CHMe}$.

From 200 g. butylene glycol and 1 g. I heated 8 hrs. below 130° is obtained 80 g. polyglycols, b. $200\text{--}350^\circ$. From 1518 g. glycerol and 0.506 g. I heated 7 hrs. at $210\text{--}5^\circ$ were obtained, besides H_2O and unchanged glycerol, 265 g. b. $169\text{--}83^\circ$, 113 g. b. $183\text{--}226^\circ$ and 346 g. b. above 226° ; reduction of the amt. of I to 0.02% appreciably diminishes the yield of polyglycerols. From 50 g. butylene glycol, 60 g. AcH and 0.3 g. I heated 4–6 hrs. on the H_2O bath is obtained 55.5 g. $\text{MeCH.O.CH}_2.\text{CHMe.O}$, b. $110\text{--}25^\circ$.

C. A. ROUILLER.

Acetolysis of carbohydrates. S. BORN AND J. M. NELSON. *J. Am. Chem. Soc.* 37, 1763–9(1915); cf. *C. A.* 8, 1435.—Sucrose and AcBr on the H_2O bath give acetobromoglucose, while AcCl yields a sirup containing halogen and reducing Fehling soln. and which is probably acetochloroglucose. From maltose and AcBr is obtained acetobromomaltose; AcCl gives a glistening white powder, m. about 65° , reduces Fehling soln., contains the amt. of Cl calcd. for *acetochloromaltose*; 25 cc. Ac_2O and 0.25 cc. H_2SO_4 give octaacetylmaltose. From lactose with AcCl is obtained a white powder; from α -methyl glucoside and $\text{Ac}_2\text{O}\text{--H}_2\text{SO}_4$, α -pentaacetylglucose; from the glucoside and AcBr, a light brown syrup; from inulin and AcBr in ice a yellow syrup reducing Fehling soln. and which when shaken with excess of Ba(OH)_2 gives a syrup yielding fructosazone. B. and N. feel justified in concluding that there is a marked difference in stability toward acetolysis by different O linkages in di- and polysaccharides and that AcCl, AcBr and $\text{Ac}_2\text{O}\text{--H}_2\text{SO}_4$ show similar acetolytic action. A bibliography of acetolysis of carbohydrates is given.

CHAS. A. ROUILLER.

Some constituents of the root of *Brauneria angustifolia*. FREDERICK W. HEYL AND MERRILL C. HART. *J. Am. Chem. Soc.* 37, 1769–78(1915); cf. *C. A.* 8, 3836.—33.3 kg. of the air-dried drug was percolated with 260 l. of 95% alc., the percolate concd. *in vacuo* to 11.5 l. and the resin completely pptd. by adding 20 l. H_2O . The aq. soln. yielded traces of a *phenolic acid*, $\text{C}_9\text{H}_{10}\text{O}_3$ (possibly a trihydroxyphenylpropionic acid), needles, m. about 207° ; 0.3% of a brown amorphous substance extd. by AmOH and giving *d*-phenylglucosazone, m. $202\text{--}3^\circ$; 0.1% of betaine; levulose and sucrose. Of the resin (628 g.), 222 g. was extd. by ligroin, 107 by Et_2O , 180 by CHCl_3 , 35 by AcOEt and 70 by alc. The ligroin ext. yielded oleic, linolic, cerotic and palmitic acids; 2 isomeric *phytosterols*, $\text{C}_{27}\text{H}_{48}\text{O}$, plates from AcOEt , m. $154.5\text{--}6.5^\circ$, $[\alpha]_D^{20} -42.2^\circ$ in CHCl_3 (*acetate*, plates, m. $131.5\text{--}2.0^\circ$), and the isomer m. $136\text{--}7^\circ$ (*acetate*, needles, m. $118\text{--}20^\circ$). The Et_2O ext. of the resin yielded a *phytosterolin*, $\text{C}_{28}\text{H}_{48}\text{O}$, m. $280\text{--}90^\circ$ (decompn.); *acetate*, m. $163\text{--}4^\circ$. No definite products were isolated from the CHCl_3 , AcOEt and alc. exts.

C. A. R.

Santonin series. XIII. Oxidation of δ -hydroxysantonin to santononic acid. E. WRECKIND. Univ. Strassburg. *Ber.* 48, 891–5(1915); cf. *C. A.* 9, 78.—When 5 g. δ -hydroxysantonin (isoartemisin) in 40 cc. of cold, freshly purified CHCl_3 is treated 2 hrs. with a moderately rapid stream of O_2 , poured upon ice, allowed to stand overnight, freed from CHCl_3 on the H_2O bath, repeatedly extd. with Et_2O and freed from neutral products in the usual way, there is obtained, instead of the expected diketone $\text{C}_{14}\text{H}_{16}\text{O}_4$, a ketonic acid, *santononic acid*, $\text{C}_{14}\text{H}_{16}\text{O}_7$ (best yield, 3 g.), crystals from AcOEt -petr. ether, decomp. 205° , $[\alpha]_D^{20} 23.08\text{--}24.03^\circ$ (alc.), 24.49° (CHCl_3); titration with 0.1 N KOH gives values intermediate between those calcd. for a mono- and a dibasic acid; it is sol. in 100 parts H_2O at room temp. and 40 parts boiling H_2O , easily reduces $\text{NH}_3\text{--AgNO}_3$, Fehling soln. only very slowly. The acid is probably identical with the yellowish syrup obtained by Angeli and Marino from santonin with alk.

KMnO₄ (*Chem. Zentr.* 1907, I, 1333; 1908, I, 1629) and by Bargellini and Gialdini with O₂ (*Atti accad. Lincei* 17, 248 (1908)). Bisphenylhydrazone, m. 98–100°, decomps. at a higher temp., easily sol. in warm NaOH but only slowly reprecipitated on acidification. Warmed with PbO₂ in AcOH, the acid loses CO₂ slowly. CHAS. A. ROULLIER.

Course of the reaction between aromatic aldehydes and diacetyl monooxime in the presence of strong hydrochloric acid. OTTO DIELS AND DONALD RILEY. Univ. Berlin. *Ber.* 48, 897–905 (1915); cf. C. A. 7, 2940.—In the presence of concd. HCl, aromatic aldehydes and AcCMe:NOH (a) do not give unsatd. 1,2-diketone oximes, but compds. of a new type (I), strong acids and distinct, though weak, bases, whose

salts are hydrolyzed by H₂O; on reduction with Zn dust in H₂O, they yield stable, faintly basic compds. (II) and with PhNCO compds. of the type (III) or (IV); (IV)

is given the preference, for while these latter compds. cannot be reduced with Zn dust and H₂O, so also (II) does not react with PhNCO, indicating that the O which disappears in the reduction is the one which reacts with PhNCO. With PhNH₂ (I) gives very unstable compds. which probably have the structure (V); the most dil. acids decomp. them quant. into Ac₂; if (CO₂H)₂ is used, besides the Ac₂ there are obtained amidine oxalates yielding, on cautious treatment with alkalis, (CO₂H)₂, PhNH₂ and the expected acid amides. Thus, from 50 g. (a), 50 g. anisaldehyde and 100 cc. of 37% HCl shaken 20 hrs., filtered, dissolved in 1 l. H₂O and 10 cc. concd. HCl, again filtered and treated with KOH, is obtained the compound C₁₂H₁₁O₄N (b), long slender needles with 1 H₂O, m. 72–80°; after dehydration for 12 hrs. *in vacuo* over P₂O₅ it m. 140–1° and becomes so unstable towards light that it must be kept in the dark; it is very stable towards alkalis and forms with acids beautifully crystd. but easily hydrolyzed salts. When 9 g. suspended in 250 cc. Et₂O and 7 g. PhNCO are shaken 3 hrs., protected from moisture, cooled several hrs., filtered, extd. with 25 cc. CHCl₃ at room temp., evapd. *in vacuo* at room temp., again extd. with 5 cc. CHCl₃, filtered, evapd. as before and crystd. twice from alc. and once each from AcOEt and MeOH, there is obtained 0.4 g. of the compound C₁₈H₁₅O₂N₃, m. 164–5°. The original Et₂O filtrate leaves on evapn. *in vacuo* at room temp. a mixt. of the above compd., diphenylurea and Ac₂. 10 g. (b) boiled 2 hrs. with 50 g. Zn dust in 30 cc. H₂O and thoroughly extd. with Et₂O yields 8.5 g. of the product C₁₈H₁₅O₂N₃, b₁₁ 175°, m. 71–2°, mol. wt. in freezing C₆H₆ 201–2, forms with acids well crystd. salts hydrolyzed by H₂O, does not react with NH₃, PhNH₂ or PhNHNH₂; cautiously warmed with 10 parts of 9% HNO₃, it first forms the nitrate, which crysts. out, but soon redissolves and as the temp. rises energetic reaction sets in and H₂O, Ac₂ and MeNO₂ or EtNO₂ distil over; on further heating to incipient turbidity and cooling, anisic acid seps. almost quant. and the mother liquors, on being made alk., deposit a very small amt. of crystals m. 164–5°. Heated 6 hrs. at 100° with 4 g. PhNH₂ and stirred up with 10 cc. of 50% AcOH, 10 g. of (b) give the anilide, C₁₈H₁₅O₂N₂, m. 164°, decompd. by acids into Ac₂, PhNH₂, NH₃ and anisic acid; if 4 g. is boiled with 80 cc. of 5% (CO₂H)₂ until there is no more odor of Ac₂ (which is evolved quant.) and cooled, crystals of an oxalate, C₁₈H₁₅O₄N₃·2H₂O, m. 157°, sep.; rubbed with NaHCO₃, this gives PhNH₂ and anisamide. The compound C₁₁H₁₁O₂N, in 19 g. yield from 12 g. (a) and 15 g. BzH, long hydrated needles, m. 58–62° and,

anhydrous, $100-1^\circ$. *Reduction product*, $C_{11}H_{11}O_2N$, $b_{11} 147^\circ$, m. $50-5^\circ$. *Anilide*, $C_{17}H_{15}O_2N_2$, m. 150° , decompd. by $(CO_2H)_2$ into an *oxalate*, light gray leaflets, which with $NaHCO_3$ gives $PhNH_2$ and $BzNH_2$.
CHAS. A. ROUILLER.

Mixed mercury dialkyls. SIEGFRIED HILPERT AND GERHARD GRÜTTNER. Berlin. Ber. 48, 906-15 (1915).—Different alkyls show great differences in their affinity for Hg, and mixed Hg dialkyls can be obtained by treating an alkylmercuric halide with the Mg halide of another alkyl having less affinity for Hg. Thus, while $PhCH_2MgCl$ and $PhHgBr$ give $Hg(CH_2Ph)_2$, showing that $PhCH_2$ has greater affinity for Hg than Ph, from $PhCH_2HgBr$ and $PhMgBr$ is obtained $PhCH_2HgPh$. These mixed Hg dialkyls do not cryst., quickly decomp. into the sym. Hg dialkyls, solidify in liquid air to glassy amorphous masses, cannot be distd. even in a high vacuum and as criteria of individuality recourse was had to the phenomena of crystn. velocity. Thus, if an equimol. mixt. of $Hg(CH_2Ph)_2$ and $HgPh_2$ is heated, the eutectic begins to m. 80° and the last solid particles have disappeared at 95° ; on cooling slowly the 1st germs appear at about 70° and the crystn. velocity at this temp. is so great that the whole mass solidifies in a few sec.; if, on the other hand, the compd. $PhCH_2HgPh$ is seeded at this temp. with either $Hg(CH_2Ph)_2$ or $HgPh_2$, the crystals do not grow but, as a matter of fact, dissolve, showing that the oily $PhCH_2HgPh$ is different from the mixt. above, but after it has stood several weeks in a closed vessel, it does behave just like the mixt. Moreover, $PhCH_2HgPh$ slowly decomp. with deposition of Hg after several days at 80° , while a mixt. of $Hg(CH_2Ph)_2$ and $HgPh_2$ is not changed even at 100° . *Benzylmercury phenyl* is obtained by slowly treating 32 g. $PhMgBr$ in Et_2O with 10.5 g. powdered $PhCH_2HgCl$, allowing to stand not more than 0.5 hr., decompg. with 1% H_2SO_4 , drawing off the Et_2O , evapg. *in vacuo* at 40° , shaking the faintly yellow oil twice with 5 vols. cold alc., pouring into 200 cc. boiling alc., filtering at once, repptg. the oil by cooling, repeating the whole process twice and drying *in vacuo* over P_2O_5 at 35° ; it is difficultly sol. in H_2O and cold alc., more easily in warm alc., miscible with Et_2O , petr. ether and C_4H_4 homologs, dissolves considerable $Hg(CH_2Ph)_2$ and $HgPh_2$ at room temp., at once gives with cold neutral or faintly acid $AgNO_3$ a ppt. free from Ag, but Ag seps. on short boiling. *Benzylmercury ethyl*, from 4 mols. $EtMgBr$ and 1 mol. $PhCH_2HgCl$. *Ethylmercury phenyl*, from $PhMgBr$ and $EtHgCl$. *Benzylmercury o-tolyl*, in 6 g. yield from 20 g. MeC_6H_4MgBr and 9.5 g. $PhCH_2HgBr$, eagerly absorbs I with formation of $PhCH_2HgI$, dissolves considerable $Hg(CH_2Ph)_2$ at room temp., less $Hg(C_6H_4Me)_2$, decomp. in a few hrs. at 80° into $(PhCH_2)_2$, Hg and $Hg(C_6H_4Me)_2$. The $PhCH_2HgCl$ was prepd. by adding to 23.8 g. $PhCH_2MgCl$ in 100 cc. Et_2O 46.7 g. powdered $HgCl_2$ in 2 g. portions, allowing to stand 24 hrs., boiling 2 hrs., decompg. with ice and H_2SO_4 and treating like $PhHgBr$ (C. A. 7, 2750) except that the H_2O used to wash out the excess of $HgCl_2$ is not heated above 80° ; it seps. from equal vols. of xylene and alc. in leaves, m. 104° ; yield, 43 g. *o-Tolylmercuric bromide*, in 42 g. yield from 28 g. MeC_6H_4MgBr and 58 g. $HgBr_2$ in 100 cc. Et_2O , shaken 1 hr., boiled 2 hrs. and allowed to stand overnight, hair-like needles from xylene or alc., m. 168° , not sensitive to light. *Iodide*, obtained quant. from the bromide boiled 2 hrs. with a slight excess of alc. KI, granules and short prisms from alc., m. $176-7.5^\circ$. *Sulfide*, from the iodide and H_2S in $C_6H_5N-Et_2O$ at -10° , white powder gradually becoming yellowish, stable for several days when dry, soon decomp., when moist, with sepn. of PbS , decomp. completely on heating. *p-MeC₆H₄HgBr*, in 44 g. yield from 28 g. MeC_6H_4MgBr and 58 g. $HgBr_2$, needles from C_6H_6 , m. $234-5^\circ$ when heated rapidly (Pope and Gibson, C. A. 6, 3266, give 228°). *Iodide*, m. 217° .
C. A. R.

Some new derivatives of glucose and cellobiose. GÉZA ZEMPLÉN AND EDUARD D. LÁSZLÓ. Budapest. Ber. 48, 915-26 (1915).—The following pentaacyl derivs. of glucose are difficultly sol. in alc. and H_2O (and consequently very difficult to hydrolyze)

and in cold acetone, but easily sol. in Et₂O, petr. ether and CS₂, while the RO₂CO derivs. are difficultly sol. in the last 3 solvents. *β*-Pentaisovalerylglucose, obtained in 6.5 g. yield from 5.4 g. *β*-glucose in 1.3 g. C₄H₉N and 70 cc. cold CHCl₃ treated with 19.8 g. C₄H₉COCl in 50 cc. CHCl₃ in small portions, shaken about 15 min., evapd. *in vacuo*, treated with alc., again evapd., suspended in 40 cc. hot alc. and cooled, long needles, sinters 90°, m. 92°, [α]_D²⁰ 91° in CHCl₃. *α*-Pentalaurylglucose, in 4.5 g. yield from 1.8 g. *α*-glucose and 10.9 g. C₁₁H₂₃COCl shaken 4 hrs. and allowed to stand 24 hrs., long needles from CHCl₃-alc., sinters about 48°, m. 52° when heated rapidly, [α]_D²⁰ 40.62°. *β*-Compound, in 6 g. yield from 1.8 g. *β*-glucose after 15 min. shaking, needles from CHCl₃-alc., sinters 60°, m. 66°, [α]_D²⁰ 3.9°. *α*-Pentapalmitylglucose, in 11 g. yield from 1.65 g. *α*-glucose and 13.7 g. C₁₅H₃₁COCl after 8 hrs. shaking, needles from a slowly evapg. mixt. of CHCl₃ and 2 vols. alc., sinters 72°, m. 75°, [α]_D²⁰ 29.7° (Stephenson describes an amorphous compd. m. 10° lower; C. A. 8, 2156). *β*-Compound, in 8 g. yield after shaking 0.5 hr., spherical microcryst. aggregates from acetone, sinters 68°, m. 72°, [α]_D²⁰ 4.6°. *β*-Pentastearylglucose, in 22 g. yield from 1.2 g. *β*-glucose and 35 g. C₁₇H₃₅COCl after 12 hrs. shaking, spherical microcryst. aggregates from acetone, sinters 72°, m. 78°, [α]_D²⁰ 14.12°. *β*-Pentacarbomethoxyglucose, in 3.5 g. yield from 6.6 g. *β*-glucose and 19 g. ClCO₂Me shaken 2 hrs., microscopic rhombic plates from 75% MeOH, sinters 121°, m. 122-3°, [α]_D²⁰ 1.35°. *Carboethoxy compound*, in 8.5 g. yield from 5.4 g. *β*-glucose and 18 g. ClCO₂Et shaken 0.5 hr., columns or thick plates from MeOH, sinters about 100°, m. 102°, [α]_D²⁰ 2.47°. *β*-Tetraacetylbenzoylglucose, in 85% yield from 10 g. acetobromoglucose (a) heated 0.5 hr. on the H₂O bath with 10 g. AgOBz in 60 cc. C₄H₈, prisms from alc., sinters 143°, m. 146°, [α]_D²⁰ -28.1°. *β*-Tetraacetylsalicylglucose, in 1.2 g. yield from 5 g. (a) and 6 g. Ag salt boiled 2 hrs., prisms from alc., m. 184°, [α]_D²⁰ -43.4°. *Hippuryl compound*, in 2.5 g. yield from 10 g. (a) and 12 g. Ag salt boiled 4 hrs., needles from acetone, sinters 191°, m. 193°, [α]_D²⁰ 3.64°. *β*-Heptaacetylbenzoylcellobiose, in 85% yield from 1 part each of acetobromocellobiose (b) and AgOBz boiled 2 hrs., slender needles from alc., sinters 205°, m. 210°, [α]_D²⁰ -30.5°. *Salicyl compound*, in 5.5 g. yield from 15 g. (b) and 12 g. Ag salt boiled 4 hrs., needles from MeOH, m. 221-3°, [α]_D²⁰ -43.43°. *Hippuryl compound*, in 5 g. yield from 15 g. (b) and 10 g. Ag salt boiled 6 hrs., needles from MeOH, sinters 182°, m. 186°, [α]_D²⁰ -15.04°.

CHAS. A. ROUILLER.

The chromoisomerism of *p*-dihydroxyterephthalic acid derivatives as phenol-enol isomerism. A. HANTZSCH. Ber. 48, 797-816(1915); cf. preceding abstr.—The chromoisomerism of free dihydroxy-*p*-phthalic acid (a) and its esters (b) is entirely analogous to that of the salts of (b) and the 2 forms may be represented by the formulas (I) and (II) (R = H, Me or Et). This has been established by the isolation of a colorless and a yellow form of the di-Cl deriv. of the Me ester, whose solns. are colorless or yellow, depending on the nature of the solvent, and optically identical with those of the Et ester (which is stable only in the colorless form) and therefore they are present in these solns. only in monomol. form (C. A. 6, 9). The absorption of the free phenol derivs., containing labile H atoms, is greatly influenced by the nature of the solvent and by temp. whereas all derivs. in which the phenol H is replaced by immobile org. residues are practically optically const. in all media and at all temps. between 0° and about 90°. The colorless solns. in MeOH are optically almost identical with those of the MeO deriv., C₆Cl₂(OMe)₂(CO₂R)₂. The yellow esters are also acids, *i. e.*, HO and not ketone-like quinonehydro derivs., as they form salts. Among the reasons for preferring the formulas (I) and (II) to the simple formulas C(OH) : C.CO.OR and CO.C : C(OH).OR

are the following: The latter would imply great differences in the isomers while as a matter of fact their spectra are very similar and differ only in the position, not the form, of the absorption curve; correspondingly, in (I) and (II) there is the same 6-membered ring, the only difference being in the positions of the single, double and secondary bonds. Secondly, the simple formula for the quinoid form contains no acid group, only $>C(OH)_2$. The *dimethyl dichlorodihydroxyterephthalates* (c) are prepd. exactly like the Et ester (*Ber.* 20, 1312(1887)); the *colorless form* seps. exclusively on rapid cooling of a boiling satd. Et_2O soln. and on addition of H_2O to a MeOH soln., while H_2O ppts. the *yellow form* from EtOH; on slow evapn., mixts. of both generally sep. from these and other solvents. In the solid form, the yellow passes smoothly into the white ester at temps. above 135° ; it then m. 177° to a yellow liquid giving the yellow ester on cooling unless it is seeded with the colorless ester. So far, no chem. differences have been detected in the 2 forms. The yellow form of the di-Et ester is so unstable that thus far it has been isolated in solid form only transitorily from very concd. hot C_6H_6 soln. Mol. extinction detns. show that the color intensity, i. e., the increase in concn. of the yellow ester at the expense of the colorless ester, increases with variation of the solvent in the order H_2O , MeOH, EtOH, $C_6H_{11}OH$, Et_2O , AcOH, $CHCl_3$, CCl_4 , C_6H_6 ; the absorption curves are shifted considerably towards the red in the same order but remain very similar to each other in form. That in aq. MeOH practically only the colorless form is present is shown by the fact that addition of H_2O to the MeOH soln. produces only a very slight shifting towards the violet, and on addition of HCl the aq. alc. soln. remains optically const., being almost identical with that of *diethyl dichlorodimethoxyterephthalate*; this ester, prepd. from the yellow di-K salt of (c) with MeI or Me_2SO_4 , seps. from alc. in needles, m. 177° , easily sol. in most media with strong blue-yellow fluorescence but without color even in $CHCl_3$ and C_6H_6 ; it is optically const. in all solvents. Heating the alc. soln. of (c) to 60° shifts the absorption towards the red, cooling to 0° towards the violet, while the curves for the colorless soln. in aq. MeOH and the yellow soln. in $CHCl_3$ are practically unchanged between 0 and 60° . *Dimethyl dibromodihydroxyterephthalate*, m. 205° to a yellow liquid quickly becoming colorless on solidifying; the *diiodo ester* decomps. 188° . The colorless *dimethyl dihydroxyterephthalate* can be obtained only by sublimation and spontaneously passes over into the *yellow-green form*, in which form almost exclusively it exists in all solvents; all its solns. are yellow-green and optically very similar and are unchanged by heating. The solns. of the di-MeO ester (Nef, *Ann.* 258, 297) show greenish blue fluorescence but are colorless. The yellow-green anhydrous $C_6H_4(OH)_2(CO_2H)_2$ is an enol or pseudo acid, the colorless dihydrate a true phenol, while the opposite holds for the colorless anhydrous di-Cl deriv. and its yellow-green dihydrate; in solns. the acids behave very much like their esters. This work shows that MeO and HO groups have optically (almost) the same effect, and stronger color and absorption in a HO compd. as compared with the MeO deriv. cannot be explained by Kauffmann's theory of increased splitting of valence but is due to constitutional change, generally rearrangement.

CHAS. A. ROUILLER.

Constitution of the phenolaldehyde salts. H. PAULY. *Ber.* 48, 934-7(1915).—Answer to Hantzsch (preceding abstr.). P. does not abandon his view that H.'s rearrangement rule does not hold for the phenolaldehyde salts. CHAS. A. ROUILLER.

Derivatives of indole and methylindole containing sulfur. W. MADELUNG AND M. TENCER. Univ. Freiburg i/Br. *Ber.* 48, 949-53(1915).—In the hope of obtaining an indole mercaptan, 12 g. indole was added to $EtMgBr$ (from 2.5 g. Mg and 11 g. $EtBr$ in 100 g. Et_2O) and, after the evolution of C_2H_4 had ceased, 3.2 g. fine S powder was introduced with turbing; after standing several hrs. the Et_2O was filtered off and the solid washed with HCl and recrystd. from alc.; this gave 5 g. *diindolyl*

sulfide (a), $C_{14}H_{12}N_2S$, needles from xylene, m. 232° , indifferent towards chem. reagents, forms no addition products with acids (even picric and $HClO_4$), only H_2SO_4 producing an orange color; all tests for NH groups were negative, neither HNO_3 nor long boiling with Ac_2O producing any change; it is quite stable towards oxidizing agents such as $KMnO_4$ and cannot be converted into the sulfone; boiling alc. KOH produces only slight decompn.; heated above its m. p., it evolves indole. α, α' -Dimethyldiindolyl *sulfide*, obtained in the same way from α -methylinole, m. 226° , gives a transitory blue color with H_2SO_4 . Indolemagnesium bromide (b) treated with excess of SO_2 in Et_2O gives *diindolyl sulfoxide*, needles from dil. alc., m. 157° (decompn.), reduced to (a) by Zn dust in AcOH on the H_2O bath; in general it shows the same indifference towards chem. reagents as (a) but is less stable, partially decompg. into indole and SO_2 ; on long boiling in soln. with SCl_2 , (b) gives (a). C. A. R.

Some reactions of indole. W. MADLUNG. Univ. Freiburg i/Br. *Ber.* **48**, 953-5 (1915).—In an attempt to prep. diindolyl sulfide (cf. preceding abstr.) in another way, 10 g. indole and 4 g. S were heated 2 hrs. at $180-90^\circ$, cooled, extd. with acetone, the ext. pptd. with aq. Na_2S and the ppt. (3 g.) crystd. from acetone. It was found to be a S-free compound, $C_{14}H_{12}N_2$, needles, m. 319° (partial decompn.) on slow, 326° on rapid heating, mol. wt. in freezing $C_{10}H_8$ 206, sol. in H_2SO_4 with yellow color turning green on warming, gives with weak oxidizing agents ($FeCl_3$, dil. Br or I) a difficultly sol. green product, forms fluorescent solns. sensitive to air and gradually turning green on standing, shows no basic properties or tendency to form addition products (picrate), cannot be acylated; with concd. HNO_3 it gives isatin. Methylinole does not yield an analogous product. With PhNO and a few drops of alc. KOH, indolone does not yield a ppt. of the anil as is the case with its homologs; reaction sets in at room temp. and the soln. becomes yellow but, instead of a ppt. forming, PhNC is evolved; probably the anil, $C_6H_4.C:(NPh).CH:N$, is first formed but decomp. at room temp. into 2 mols. PhNC. C. A. R.

γ -Substituted piperidines. ERNST KOENIGS AND LUDWIG NEUMANN. Univ. Breslau. *Ber.* **48**, 956-63 (1915); cf. Emmert and Dorn, *C. A.* **9**, 2093.— γ -Hydroxypiperidine, obtained in 30% yield (together with 50% unchanged γ - C_6H_4NOH) from 1 part C_6H_4NOH and 4 parts Na in 25 parts alc., m. $86-7^\circ$, b_{748} $212-3^\circ$, b_{82} 136° ; HCl salt, hygroscopic needles from alc.- Et_2O , softens above 142° , m. $146-8^\circ$; *chloroaurate*, yellow needles, m. $206-9^\circ$; *chloroplatinate*, yellow-red needles from alc., m. $184-7^\circ$ (decompn.); *sulfate*, non-hygroscopic needles from alc.- Et_2O , m. $263-6^\circ$. γ -Hydroxypyridine *propyl ether*, from γ - C_6H_4NCl heated 8 hrs. at 150° with Na in excess of $PrOH$, alk. liquid, b_{742} $218-20^\circ$; *hydrochloride*, long needles from alc.- Et_2O , m. $156-7^\circ$; *chloroaurate*, light yellow needles, m. $147-50^\circ$; *chloroplatinate*, ocher-yellow feathery prisms, m. $192-5^\circ$; *picrate*, moss-like prisms from alc., m. $120-4^\circ$. *Phenyl ether*, obtained with concd. aq. alk. PhONa after 10 hrs. at 150° (in alc. soln. γ - C_6H_4NOEt is also formed), m. $45-6^\circ$, b_{10} $134-6^\circ$, b_{760} $277-9^\circ$ (slight decompn.); *hydrochloride*, m. $177-8^\circ$; *chloroaurate*, yellow, m. $159-62^\circ$; *chloroplatinate*, orange, m. $196-7^\circ$; *chromate*, orange-red, sinters 125° , m. 130° (decompn.). Reduction of the above ethers with Na and alc. always gave piperidine as the chief product with a little of the piperidine ethers and none of the piperidine ethers. γ -Methoxypiperidine, $C_6H_{11}ON$, b_{11} $61-5^\circ$, absorbs H_2O and CO_2 from the air; *chloroaurate*, red, unstable crystals. γ -Phenoxypiperidine, yellowish, b_{11} $143-6^\circ$. γ -Hydroxypiperidine *hydrochloride*, crystals with 1 H_2O , m. $94-6^\circ$, and, anhydrous, $147-9^\circ$. γ -Aminopiperidine, from $C_6H_4NNH_2$, Na and alc., strongly alk., hygroscopic, sensitive to CO_2 , evolves heat when dissolved in H_2O , is diacid; HCl salt, m. $333-4^\circ$ (decompn.); *chloroaurate*, yellow-red; *chloroplatinate*, turns brown above 240° , m. $266-7^\circ$ (decompn.). γ -Bromopiperidine *hydrobromide*, in 4.5 g. yield from 3 g. hydroxypiperidine heated 8 hrs. at 150° with 24 g. of 66% HBr, m.

192–3°; *hydrochloride*, non-hygroscopic prisms, m. 188–9°; *chloroaurate*, orange-yellow prisms, m. 171–2°; *chloroplatinate*, yellow moss-like needles, m. 213–4°. γ -*Iodopiperidine hydriodide*, in 76% yield from hydroxypiperidine heated 5 hrs. at 150° with excess of HI (d. 1.96), needle-shaped prisms, m. 170–2°; *hydrochloride*, needles, m. 175–8°; *chloroaurate*, reddish yellow needles, m. 147° (decompn.); *chloroplatinate*, ocher-yellow needles, m. 187° (decompn.); free *base*, odorless when dry, smells of piperidine and impure AcNH_2 when moist, decompn. on distn., even *in vacuo*. In alk. solns. the above halogenpiperidines lose halogen acid and give piperidines. C. A. R.

Phthalidenephenylisocrotonic acid. W. BORSCHÉ AND G. HEIMBÜRGER. Univ. Göttingen. *Ber.* 48, 966–72 (1915); cf. C. A. 9, 302.— α -*Phthalidenephenylisocrotonic acid* (a), $\text{O.CO.C}_6\text{H}_4\text{C:C(CO}_2\text{H)CH:CHPh}$, yellow needles from AcOH, m. 252°,

becomes orange when moistened with H_2SO_4 , is obtained in 14–5 g. yield when 18.4 g. $\text{PhCH:CHCH}_2\text{CO}_2\text{Na}$ is heated 12–4 hrs. on the H_2O bath with 14.8 g. $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$ and 20 cc. Ac_2O . It easily dissolves with yellow color in the calcd. amt. of dil. soda on gentle warming and is pptd. unchanged by acids, but if it is boiled for a short time with excess of soda, acids ppt. a yellowish flocculent amorphous substance which quickly balls together, with evolution of CO_2 , to a viscous tar which smoothly dissolves in cold NaOH and is apparently ω -*styrylacetophenone-o-carboxylic acid*, which is converted by HCl-AcOH or short boiling with alc. H_2SO_4 into *phthalidenestyrylmethane* (b) (see below). In soda the acid combines with diazobenzene to an azo compd. pptd. by acids in red amorphous flocks; with PhNHCONHNH_2 , $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ and PhNHNH_2 it gives only amorphous products. (b), also obtained (but in very impure form) by heating (a) at about 270° until the evolution of gas ceases but best by boiling 10 g. (a) with 90 cc. alc. and 10 cc. H_2SO_4 until dissolved (yield, 80%), light yellow cryst. powder, m. 144–5°; when boiled with H_2O , alc. and a little soda it dissolves clear and acids ppt. the above acid; in dry CHCl_3 it smoothly adds only 1 mol. Br_2 , the *dibromide* sepg. from AcOEt in silky needles, m. 159–60° (foaming); it is unchanged by PhNHNH_2 in AcOH after several hrs. heating, while with N_2H_4 it gives a substance which in neither basic nor acid, probably the *phthalazone*, $\text{C}_6\text{H}_4\text{CO.NH.N:CCH}_2\text{CH:CHPh}$, yellowish flat needles

from alc., m. 201°; this is also formed directly from (a) and $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$, but in alc. some phthalic hydrazide is also formed. 2-*Styryl-1,3-diketohydriindene*, $\text{PhCH:-CHCH.CO.C}_6\text{H}_4\text{CO}$, obtained in 90% yield from 6.2 g. (b) in 125 cc. MeOH gently

warmed with 0.6 g. Na in 60 cc. MeOH until a clear, dark red soln. results, acidified, allowed to stand until the violet amorphous flocks become white (rearrangement of the enol into the diketone?) and crystd. from alc., needles, m. 162°, forms cryst. derivs. with PhNHCONHNH_2 and NH_2OH and is converted by PhNHNH_2 and AcOH into a dark brown resin. α -*Phthalidyl- γ -phenylbutyric acid*, from (a) in the calcd. amt. of soda with H and Pd colloid, yellowish viscous mass, converted by alc. H_2SO_4 into the *ethyl ester*, silky needles from ligroin, m. 68–9° CHAS. A. ROULLER.

Benzoylanthraquinones. ALFRED SCHAARSCHMIDT. Berlin. *Ber.* 48, 831–9 (1915).—1-*p*-*Chlorobenzoylanthraquinone* is obtained in 25 g. yield when 35 g. $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_4\text{COCl}$ in 180 g. PhCl at 15–20° is treated in the course of 0.5 hr. with 40 g. AlCl_3 in 3 portions, shaken 0.5 hr. more at the same temp., allowed to stand 0.5 hr. at 25°, heated 3 hrs. at 40–60°, allowed to cool overnight, poured upon ice, treated with 40 cc. HCl, freed from excess of PhCl by steam distn., filtered, washed with HCl and hot H_2O , boiled up with dil. NH_4OH until the filtrate is no longer green, then, while still wet, with 375 cc. AcOH, cooled, filtered, boiled with 700 cc. AcOH and charcoal and filtered boiling hot; it seps. in faintly brownish yellow platelets, m. 238°, sol. in H_2SO_4 with faint yellow color which becomes intensely green on addition of a few particles of

Cu bronze and H_2O produces an intensely violet-blue ppt.; the soln. in alk. $Na_2S_2O_4$ is red. In 1 prepn., after the extn. with NH_4OH , the crude product was boiled up twice with 6 parts alc., then 4 times with 6 parts AcOH; the 1st of the AcOH exts. yielded what was apparently the isomeric *1-o-chloro compound*, snow-white powder from AcOH, m. 177° , sol. with orange color in H_2SO_4 and, only slightly, in $Na_2S_2O_4$; towards Cu bronze, however, the H_2SO_4 soln. behaves like that of the *p*-compd. The latter with $N_2H_4 \cdot H_2O$ in boiling PhMe quant. gives the *o*-diazine, $C_{21}H_{11}ON_2Cl$, yellow needles from AcOH, m. above 300° , sol. in H_2SO_4 with red color and in org. solvents with green fluorescence. *1-Benzoylanthraquinone*, obtained with C_6H_6 instead of PhCl, faintly yellowish white cryst. powder, m. 229° , sol. in alk. hydrosulfite with red, in H_2SO_4 with faint yellow color turning green with Cu bronze and forming an intensely blue ppt. with H_2O . *1-p-Toluylanthraquinone*, obtained in 20 g. yield from 40 g. $C_6H_4(CO)_2C_6H_5CO_2H$ boiled with 36 g. PCl_5 in 150 cc. PhMe till the evolution of HCl ceases, cooled, treated with 150 cc. more PhMe and, in the course of 0.5 hr., with 40 g. $AlCl_3$ at $15-20^\circ$, thick plates from AcOH, m. 200° , sol. in $Na_2S_2O_4$ with red, in H_2SO_4 with yellow color turning green with Cu or Al and giving an intensely blue ppt. with H_2O . *1-p-Methoxybenzoylanthraquinone*, m. 269° , behaves in the same way with H_2SO_4 and Al. *2-p-Toluylanthraquinone*, obtained in 58 g. yield from 50 g. $2-C_6H_4(CO)_2C_6H_5COCl$ in 400 cc. PhMe at $40-5^\circ$ treated in the course of 0.5 hr. with 50 g. $AlCl_3$ and heated 4 hrs. at $65-75^\circ$, m. $181-2^\circ$, gives an intensely green vat which, however, has no affinity for plant fibers; the H_2SO_4 soln. is faintly yellow and hardly changed by Cu powder. *2-m-Chlorotoluyyl compound*, forms a red-brown vat. *1-Chloro-2-p-toluyyl compound*, obtained in 19 g. yield from 25 g. $1,2-C_6H_4(CO)_2C_6H_5ClCO_2H$ in 250 cc. PhMe boiled 0.5 hr. with 22 g. PCl_5 , cooled, treated with 22 g. $AlCl_3$ and heated 2 hrs. at $50-70^\circ$, m. 193° , sol. in $Na_2S_2O_4$ with red-brown color.

CHAS. A. ROUITLER.

A new class of colored reduction products of 1-benzoylanthraquinones or 2,3-phthaloylbenzophenones. I. Preliminary communication. ALFRED SCHAARSCHMIDT. Berlin. Ber. 48, 973-8(1915); cf. preceding abstr.—When 3 g. *1-p*- $ClC_6H_4COC_6H_4(CO)_2C_6H_4$ in 60 g. cold concd. H_2SO_4 is treated at room temp. with 0.09 g. Al bronze (= 1 atom H), the faintly yellow soln. soon becomes intensely green; after all the Al has dissolved (about 1.5 hrs.), there sep. out emerald-green needles, which are washed on glass wool with cold H_2SO_4 until the washings are only faintly green (the dark green mother liquors yield more of the product when treated with ice as long as a green ppt. is formed and until the dild. H_2SO_4 is colorless). The crystals show red-violet surface luster in incident light and in H_2O change into an intensely red-violet product insol. in H_2O and dil. acids and which, washed free from acid with H_2O at 50° and dried *in vacuo* over P_2O_5 , sinters 218° , m. $220-2^\circ$. Its comp. is $C_{21}H_{11}O_2Cl$. It dissolves in H_2SO_4 with green color and on slow diln. with H_2O the green "intermediate product" first seps. and on further diln. passes over into the blue "end product." The limit of H_2SO_4 concn. above which the green product is still stable is about 50%. If the green crystals still moist with concd. H_2SO_4 are stirred with HCl (d. 1.19), the green color persists but washing with concd. HCl converts the crystals into the blue form. Quickly warmed with alk. $Na_2S_2O_4$, the blue compd. forms a red-brown soln. on whose surface air forms a film of the regenerated blue compd.; if the vat is warmed longer, the soln. does not change color but air no longer produces a blue film. Cotton dipped in the original vat, squeezed out and washed with H_2O , acquires in the air a very faint blue color. In org. solvents the blue product is but slightly sol. and in the higher boiling solvents decompn. apparently occurs. The solns. prepd. cold show characteristic color and fluorescence phenomena, depending on the nature of the solvent; in aliphatic and aromatic hydrocarbons, C_6H_5N and $PhNMe_2$, small amts. of the compd. produce scarlet fluorescent solns. red in transmitted light; EtOH, AmOH, PhOH, $PhNH_2$ and

AcOH solns. are intensely blue without fluorescence, while Ac_2O gives a bluish red soln. with red fluorescence. The red solns. in hydrocarbons become blue and non-fluorescent when treated with a few drops of alc. or AcOH. The red solns. lose their color and fluorescence on standing several days, while the blue alc. or AcOH solns. are stable much longer; light is a factor in these color changes. If, in the reduction, 3-4 times as much Al bronze is used and the temp. is raised to 40-50°, $\text{Al}_2(\text{SO}_4)_3$ seps. and the reduction product remains in soln.; after filtering, ice ppts. a blue tarry substance soon becoming granular and sol. in warm H_2O with blue-violet color, the hot soln. dyeing wool and silk intensely blue-violet. The above properties of the blue reduction product are best represented by the formula $(\text{HOCRR}')_3$, ($\text{R} = \text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_5$, $\text{R}' = \text{ClC}_6\text{H}_4$), while the green intermediate product is probably a H_2SO_4 compd. of the blue compd.

Effect of some trivalent and tetravalent cations on permeability. W. J. V. OSTERHOUT. *Botan. Gaz.* 59, 464-73(1915); cf. *C. A.* 9, 1791.—All of the trivalent cations investigated (La, Ce, Y, Fe, Al) and the tetravalent cation Th decrease permeability to a marked degree.

B. H.

Influence of glycerol on alcoholic fermentation and inversion of sugar. G. ROSSI. Bologna. *Boll. chim. farm.* 53, 657-9(1914).—Definite amts. of sterilized glucose soln. (9.60 g. in 100 cc.), Pasteur nutrient soln., pure culture yeast and glycerol (in various proportions) were brought to a const. vol. of 30 cc. with distd., sterilized H_2O and the final soln. was allowed to remain for a definite time in a thermostat at 32°; a duplicate soln. without glycerol was subjected to identical conditions. Detn. of the amt. of glucose present before and after fermentation showed that the amt. of glucose fermented in 12 hrs. was not affected by amts. of glycerol varying between 1.269 g. and 3.1727 g. in 30 cc. Alc. fermentation was retarded by a conc. of 6.3455 g. glycerol in 30 cc. and totally inhibited by a conc. of 12.691 g. glycerol in 30 cc. (42.30%). Glycerol was added to a mixt. of glucose soln., Pasteur nutrient soln., pure culture yeast and H_2O in such proportion that the final conc. of the glycerol was 50 g. per 100 cc. After 12 hrs. sufficient H_2O was added to reduce the glycerol conc. to 10 g. per 100 cc. (this conc. does not even retard fermentation) and the final soln. was kept in a const. temp. app. for 24 hrs. No fermentation of glucose occurred and it is concluded that the enzyme or yeast was destroyed by the original high conc. of the glycerol. Ten cc. of a 10% sucrose soln., pure culture yeast, nutrient soln. and 15 g. glycerol were brought to a vol. of 30 cc. with H_2O and the amt. of invert sugar present was detd. after 12, 24 and 36 hrs. at const. temp. Inversion was not inhibited. [The influence of the above conc. of glycerol on the rate of inversion was not detd.—ABSTRACTOR.] H. S. PAINE.

The identity of oxidizing enzymes. G. WOKER. *Arch. sci. phys. nat.* 39, 405-14(1915); cf. *C. A.* 8, 3663.—The article is chiefly an answer to Bach's attempt to disprove Woker's theory of the identity between ferments which induce oxidation and those which induce reductions. (Cf. *C. A.* 9, 1919.) W. reports that catalase

and peroxidase when submitted to increasing temps. undergo similar changes. At first a new substance, which has no peroxidizing effect in presence of H_2O_2 and does not decompose the peroxide, is produced, but if the temp. is raised more, another new substance, which causes both changes to take place, is formed. This enzyme which is stable to heat is different, then, from the enzymes from which it was formed and it is the presence of this which enables one to speak of the re-activation of a dead ferment by means of heat. It was noticed that the action of peroxidase is much more feeble when the plant extracts have remained in contact with H_2O_2 before the addition of benzidene.

R. L. SIBLEY.

Chemical and physico-chemical properties of muscles and muscle juice. VI. The phosphorus content of white and red striated muscle. G. QUAGLIARIELLO. Univ. Naples. *Atti accad. Lincei* 24, I, 348-52(1915); cf. C. A. 9, 1637.—The muscles of various animals have been studied for various reasons but so far no comparison between the P content of white and red muscle has been made. Q. examd. muscles of the rabbit (*Lepus cuniculus*), turkey (*Meleagris gallopava*) and the cock (*Gallus domesticus*) in this way. The dry residue at 110° , the total P and the P of phosphatides were detd. The results show that the striated muscles (white or red) have a higher P content than those of other animals such as the ox. The white striated muscles have a total P content slightly higher than that of the red muscles when calcd. for the fresh muscles, but when calcd. for the dry residue it is slightly lower. The phosphatides show much difference. In the birds the P of the phosphatides represents about 11% of the total P in the white and 22% in the red muscles; in the rabbit the values are 13% and 17%, resp. It is thus concluded that the red and white muscles show no difference in total P, but marked differences in the nature of the chem. combination of the P.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

The estimation of phosphorus in biological material, and the standardization of solutions of molybdenum. A. E. TAYLOR AND C. W. MILLER. Univ. Penna. *J. Biol. Chem.* 21, 255-62(1915); cf. C. A. 8, 3311.—The modification of Neumann's method proposed by the authors is further modified as follows: The ash from material containing about 2 mg. P is dissolved in a small amt. of dil. HNO_3 and transferred to a 50 cc. centrifuge tube. The vol. should not exceed 12-15 cc. Two g. NH_4NO_3 and 10-12 drops of strong HNO_3 are added and the mixt. is heated in a H_2O -bath. When hot, 2 cc. of 10% $(NH_4)_2MoO_4$ are run directly into the liquid, without touching the sides of the tube. The contents of the tube are shaken and allowed to settle for 10 min. Not more than 5 cc. abs. EtOH are then poured around the sides of the tube and the floating ppt. freed from the sides of the tube by gentle swinging. Fifty EtOH is then floated over the mixt. until the tube is filled. This is then centrifuged, the supernatant liquid poured off, 5 cc. H_2O and 5 drops strong HNO_3 added, and the sides of the tube scrubbed with a rubber-tipped rod. Abs. EtOH and then 50% EtOH are added as described above and the tube again centrifuged. Thereafter the ppt. usually packs easily and may readily be washed with 50% EtOH (5-6 washings). The ppt. is then dissolved in 25 cc. 0.1 N NaOH and evapd. to 5 cc., when it is titrated in the usual manner. If desired the Mo, and from this the P, may be detd. by Raper's method (cf. C. A. 9, 813). The standardization of the molybdate soln. required in the author's colorimetric method is best accomplished by Raper's method or else by titration with $KMnO_4$ after reduction in a Jones reductor. In order to obviate the error due to reoxidation by the air, the receiver of the reductor is charged with H_2O and 25 cc. of the following soln.: Fe^{++} alum 100 g., H_2SO_4 25 cc., H_3PO_4 40 cc., H_2O to 1000 cc. After reduction by the reduced Mo soln., this is not readily oxidized by the air.

I. GREENWALD.

The determination of hippuric and benzoic acids in blood and tissue. F. B. KINGSBURY. Univ. Minn. *J. Biol. Chem.* 21, 289-95(1915).—*Removal of proteins.*—Blood is drawn into a tared flask containing 25% MgSO_4 soln. The vol. of soln. is about $\frac{1}{4}$ that of the blood to be drawn. After cooling the flask is weighed and a portion of the mixt., usually 60 g., is centrifuged. The plasma is poured into a small beaker and the cells hemolyzed with about 250 cc. H_2O . The plasma and hemolyzed cells are united, a drop of caprylic alcohol added and the mixt. made up to 300-400 cc. Of this, 100 cc. are treated with 2 g. tannic acid in 10-12 cc. H_2O and centrifuged. The clear, colorless supernatant liquid is poured off and the ppt. washed 4 times, using 300-350 cc. H_2O in all; the supernatant liquids are added to that first obtained. If desired the proteins may be removed by boiling the dild. blood, filtering and washing the coagulum with hot H_2O . The filtrate is evapd. on the H_2O -bath to about 30 cc., 0.5 g. (more, if necessary) tannic acid is added, the mixt. filtered and the ppt. washed with 200 cc. H_2O . The latter method is required in the case of tissues other than blood. *Detn. of benzoic acid.* The filtrate obtained by either of these methods is transferred to a 500 cc. separatory funnel (in the first method, 2 funnels are required) containing 110 g. $(\text{NH}_4)_2\text{SO}_4$. After soln., 5 cc. concd. HCl are added and the soln. extd. with neutral, EtOH -free CHCl_3 in 1-50, 1-35 and 2-25 cc. portions. The combined exts. are washed once with 100 cc. of satd. NaCl soln. containing 0.5 cc. conc. HCl in 1000 cc. The washed ext. is titrated with 0.1 N EtONa , using phenolphthalein as indicator. *Detn. of hippuric acid (total benzoic acid).* The filtrate from the tannic acid ppt. is evapd. to dryness with 20 cc. of 5% NaOH soln. The residue is treated as in the Folin-Flanders procedure for the detn. of hippuric acid (cf. C. A. 6, 2245). Blanks must be run. Benzoic and hippuric acids added to blood were quant. recovered.

I. GREENWALD.

A method for the determination of chlorides in small amounts of body fluids. FRANKLIN C. MCLEAN AND DONALD D. VAN SLYKE. Rockefeller Inst. *J. Biol. Chem.* 21, 361-70(1915); cf. C. A. 9, 1588.—Two cc. of oxalated plasma (measured in a pipet containing 2 cc. ± 0.005 cc.) are run into 10 cc. 10% MgSO_4 in a 20 cc. vol. flask and rinsed out with the soln. in the flask, 2 drops 50% HOAc are added and the mixt. heated in the H_2O -bath for 10 min. After cooling, the mixt. is poured onto 0.3 g. blood charcoal (Merck's reagent) in a small beaker and filtered after a few min. For the titration the following solns. are used: (A) AgNO_3 5.812 g., HNO_3 (sp. gr. 1.42) 250 cc., H_2O to 1000 cc.; (1 cc. = 2 mg. NaCl); (B) KI 0.3%, standardized so that 10 cc. = 5 cc. soln. A; (C) $\text{Na}_2\text{C}_4\text{H}_4\text{O}_7 + 5.5\text{H}_2\text{O}$ 446 g., NaNO_3 20 g., sol. starch 2.5 g., H_2O to 1000 cc. Ten cc. or other convenient vol. of the above filtrate, are measured into a 25 cc. vol. flask, 5 cc. Soln. A added and the mixt. dild. to 25 cc. Two drops caprylic alcohol are added and the mixt. shaken a few times. After 5 min., it is filtered and 20 cc. of the filtrate treated with 4 cc. of C and titrated with B to the appearance of a blue color. Number of g. NaCl per liter = 12.5 (8 cc. B used)/cc. blood filtrate taken. The error is less than $\pm 1\%$ and the results agree well with those obtained by incineration and titration according to Volhard. With albumin-free urine, 1 cc. is mixed in a 50 cc. flask with 10 cc. A and 2 drops caprylic alcohol, dild. to the mark, filtered and 25 cc. of the filtrate treated with 5 cc. C and titrated with B. Urine containing albumin is treated as is blood.

I. GREENWALD.

Changes in the fat content of feces preserved by freezing without the addition of a preservative. C. A. SMITH, RAYMOND J. MILLER AND PHILIP B. HAWK. Jefferson Med. College. *J. Biol. Chem.* 21, 395-401(1915).—"The fat of feces kept at -12° undergoes both hydrolysis (shown by the increase in fatty acid) and actual destruction (shown by the decrease in total fat)..... The Saxon method (cf. C. A. 8, 1799) for the detn. of fat in moist feces avoids most of the objections to which other simple

extn. methods are subject, and has the added advantage of allowing for the differentiation between neutral fat and fatty acids (free and combined as soaps)."

I. GREENWALD.

Microtechnical methods. W. J. G. LAND. *Botan. Gaz.* 59, 397-401(1915).—Descriptions of improved methods of replacing the paraffin solvent with paraffin; of fixing paraffin ribbons to the slide with certainty; of imbedding in gelatin; and of cleaning cover glass.

B. HOROWITZ.

A new method for the determination of the activity of diastase. O. WOLFF. Univ. Jena. *Chem. Ztg.* 39, 105-7(1915).—Methods previously worked out for the study of enzyme reactions, *e. g.*, the detn. of diastatic activity, are briefly reviewed. For optical methods the Zeiss interferometer is far more sensitive than the refractometer. In the 2 cm. cell a 0.2% soln. of sol. starch shows a reading of 142 as compared with H₂O, while a similar soln. of dextrose shows 200, the subjective error of the instrument being only 2 scale divisions. The interferometer may be calibrated by means of 1% solns. of sol. starch and dextrose, one cell being kept filled with the starch soln. and compared with mixts. of starch and dextrose in complementary proportions in the other cell. The differential readings are plotted with scale divisions as abscissas and g. of dextrose as ordinates, and a straight line is thus obtained from which subsequent results can be integrated, provided identical quantities of H₂O or solid matters be added to each soln. For the detn. of diastatic activity, add a known amt. of diastase (about 0.2 g.) to each of two 50 cc. portions of 1% starch soln. in 2 flasks; boil one portion immediately to destroy the enzyme and digest the other at 38° for 2 hrs. Filter both solns. through dry paper filters of the same size and compare the clear filtrates together in the cells of the interferometer. Some little difficulty may arise in obtaining perfectly clear filtrates and hence it is seldom possible to employ the 4 cm. cells, but if very small proportions of enzyme are present, the delicacy of the method may be increased by adopting a longer time of digestion. Detns. have shown that the readings obtained are proportional to the quantity of diastase within certain limits.

F. W. SMITHER.

A simple test for the detection of bile pigments and hemoglobin in urine. H. LIPP. *Münch. med. Wochschr.* 61, 1965(1914).—Gmelin's test is performed on unglazed porcelain or in a thin layer of white sand.

H. G. WELLS.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The practical applicability of acid agglutination for the recognition of typhoid bacilli. E. MICHAELIS. *Deut. med. Wochschr.* 41, 243-4(1915).—A suspension is made of a dense 24 hr. growth of a pure culture on an agar slant in about 20 cc. distd. water, which need not be sterile. In each of six test tubes are placed 3 cc. of this suspension and 1 cc. of the acid mixts. 1-6. The acid mixts. contain in 100 cc. the following amts. of *N* NaOH and *N* AcOH, resp.: (1) 5, 7.5; (2) 5, 10; (3) 5, 15; (4) 5, 25; (5) 5, 45; (6) 5, 85. The tubes are shaken and put in an incubator 1/2-2 hr. The optimum agglutination is easily recognizable. The optimum for typhoid bacilli is No. 3, the paratyphoid group No. 5-6. Coli and dysentery bacilli are, as a rule, not agglutinated at all. The acid agglutination is next to the specific serum agglutination, the most constant characteristic of typhoid bacilli.

S. AMBERG.

D. BOTANY.

CARL L. ALSBERG.

Variations in respiratory activity in relation to sunlight. H. A. SPOEHR. *Botan. Gaz.* 59, 366-86(1915).—In S.'s expts. (mostly with wheat seedlings) the CO₂ production in the dark at constant conditions of temp. and humidity was measured by drawing air from out-of-doors over plants, and then through a standard Ba(OH)₂ sofn. It

was found that the rate at which CO_2 was produced in daytime was regularly higher than that at night. Expts. with deionized air were also conducted with a view to finding whether or not activity and atmospheric ionization, resp., were related. For the following materials the ratio of the day rate to the night rate in normal air and the same ratio in deionized air are, resp.: Onion, 1.150, —; wheat 1.042, 1.010; wheat 1.091, 1.014; beetles 1.099, —.

B. HOROWITZ.

Evidence for the general distribution of oxidases in plants. G. B. REED. *Botan. Gas.* 59, 407-9(1915).—Tissues markedly acid in reaction and those said to contain large amts. of reducing substances have been reported to be without oxidases. Modified methods of investigation have convinced R. that this is not the case; that, in fact, "oxidases are universally distributed in living plants."

B. HOROWITZ.

Specific action of organic compounds in modifying plant characteristics; methylglycocoll versus glycocoll. O. SCHREINER AND J. J. SKINNER. *Botan. Gas.* 59, 445-463(1915).—Wheat plants were grown in nutrient culture solns. composed of fertilizer salts, used singly and in combinations of 2 or 3 salts. Glycocoll, in solns. free from nitrate but containing various amts. of phosphate and potash, stimulated growth. Methylglycocoll caused a decrease in growth.

B. HOROWITZ.

The acid secretion of the gram plant, *Cicer arietinum*. D. L. SAHASRABUDDHE. Poona Agr. College, Agr. Res. Inst., Pusa, 1914, *Bull.* No. 45, 12 pp.; *J. Soc. Chem. Ind.* 34, 439.—The acidity of this secretion is due to malic, oxalic, and a small quantity of acetic acids. There is a marked and fairly sudden rise in the amt. of acidity at the time of flowering, after which the quantity remains steady until the pods are formed. When this occurs there is another rapid rise in the quantity of acids produced; this is maintained until the plants, including the pods, begin to dry, when the quantity rapidly declines. The proportion between malic and oxalic acids is const. from the tenth week onwards, 94% malic and 6% oxalic acids. The oxalic acid content is highest when the plants are dry. While the compn. of the acids from the normally grown and from the pruned plants is approx. the same, the amt. of dry matter per plant is greater with pruned plants and the amt. of acids per 100 parts of dry matter in the plant is considerably greater. The plant is continually producing acid, and it is secreted in sufficient quantity for the normally found amt. on the plant to be produced in a week. Continual washing appears to exhaust the acid-producing power of the plant, but it is evident that washing up to a certain point stimulates the production. Washing every 6 days is considered the most favorable. The acid production is greater where knobbed hairs are most abundant. The probable yield of malic acid, from 9 to 18 weeks, is 2686.8 g. The removal of the acid secretion from the plant in the customary manner has no effect on the vitality of the plants.

W. H. FRY.

E. NUTRITION.

PHILIP B. HAWK.

NORMAL.

Basal metabolism and body surface. A contribution to the normal data. JAMES H. MEANS. Mass. Gen. Hosp. *J. Biol. Chem.* 21, 263-8(1915).—The surface area, calcd. from the formulas of Meeh and Du Bois and Du Bois (cf. *C. A.* 9, 1795) and the basal metabolism per sq. m. of body surface are given for 16 normal persons. By the Meeh formula, the average is 31.5 cal. per sq. m. and hour; by the Du Bois formula it is 38.8 cal. The deviation from the average is smaller in the latter case (always less than $\pm 10\%$) than in the former. In hypo- or hyperthyroidism, the basal metabolism lies well without this zone.

I. GREENWALD.

Synthesis of hippuric acid in the animal organism and the occurrence of free benzoic acid in the urine. G. W. RAIZISS AND H. DUBIN. *J. Biol. Chem.* 21, 331-

43(1915).—Hippuric acid is readily decomposed in urine, particularly when alk. The urine should be collected in acid (dil. HNO_3). In rabbits receiving not more than 1 g. of benzoic acid per kg., the conversion into hippuric acid is practically quant. With larger doses from 10 to 20% of free benzoic acid appears in the urine. A diet of milk and eggs increases the capacity of the organism to synthesize hippuric acid, as much as 96% of nearly fatal doses of benzoic acid being conjugated. There is an increase in the proportion of benzoic acid synthesized into hippuric acid after the first day, also after repeated administration of benzoic acid. Of the non-conjugated benzoic acid, the largest amt. appears in the urine in the first 6 hrs. after feeding. (Cf. C. A. 9, 920). I. GREENWALD.

The metabolism of creatine and creatinine. VII. The fate of creatine when administered to man. VICTOR C. MYERS AND MORRIS S. FINE. N. Y. Post-Graduate Med. School. *J. Biol. Chem.* 21, 377-81(1915).—After a fore-period of 6 days on a meat-free diet, the authors each ingested creatine, 1 g. on the first day, increasing the dose by 1 g. per day until 5 g. were taken on the 5th day. There was a slight increase in the urinary creatinine (3-4%) and an excretion of creatine varying from none on the first day to about 25% of the ingested quantity on the last 3 days in one case and from 20% on the first day to 37% on the last day in the other. The excess creatinine excreted is believed to be derived from the creatine ingested. VIII. The presence of creatinine in muscle. *Ibid* 383-7(1915).—As a result of a large number of analyses, M. and F. conclude that creatinine is a normal constituent of muscle and that muscle is the chief creatinine-forming tissue. The normal concn. is about 6 mg. per 100 g. of muscle and is much less than this in blood. In uremic persons or in nephrectomized rabbits, the blood may contain more creatinine than muscle. IX. The creatine content of the muscle of rats fed on isolated proteins. *Ibid* 389-93.—M. and F. detd. the creatine content of the muscle of rats kept on a normal mixed diet and on diets containing either casein, lactalbumin or edestin as the sole protein. The muscles of rats on a casein diet (poor in arginine) contained slightly less (2.5%) creatine than did those of rats kept on a normal or edestin diet. (Cf. C. A. 8, 1132). I. GREENWALD.

The occurrence of methyl alcohol in urine in different kinds of nutrition. T. VON FELLEBERG. *Mitt. Lebensm. Hyg.* 6, 24-37(1915).—MeOH in urine was detd. by the author's modification of the Dénigès method (cf. C. A. 9, 1887). On a pectin-free diet very small amts. of MeOH occur in the urine (about 0.4-1.0 mg. per 750 g.), and on a fast it is reduced one-half. On a diet rich in pectin the amt. increases to 0.8-2.5 mg. The condition of the pectin, whether raw, containing pectase, or cooked and pectase-free, makes little difference in the MeOH secretion. The use of EtOH on a pectin-free diet raises the MeOH content slightly; with pectin there is a large increase. Cheap wines containing both MeOH and EtOH cause a max. rise. F. discusses briefly the pathological effects of MeOH on the system. H. L. OLIN.

Nutrition and growth. LAFAYETTE B. MENDEL. New Haven. *J. Am. Med. Assoc.* 64, 1539-47(1915).—An address (cf. C. A. 8, 3578). L. W. RIGGS.

Feeding experiments with young swine, making comparison of skim milk, granulated blood and extracted fish meal. KLEIN. *Milchwirtsch. Zentr.* 44, 81-7(1915).—Three lots of young swine were given rations containing the same amts. of digestible nutrients. Each ration contained skim milk, barley, barley bran and potatoes; the first contained a relatively large amt. of skim milk; the second, less skim milk but some granulated blood; the third still less skim milk but some fish meal. The av. increase of wt. per animal was 33.4 kg. on the first ration, 31.8 kg. on the second (blood) and 31.1 kg. on the third (fish meal). The addition of blood and of fish meal slightly increased the cost of the ration. L. L. VAN SLYKE.

Further observations of the influence of natural fats upon growth. THOMAS B. OSBORNE AND LAFAYETTE B. MENDEL. Conn. Agr. Expt. Sta. and Yale Univ. *J. Biol. Chem.* 20, 379-89(1915).—Lard, prepared in the lab. by filtration at a temp. just above its m. p., fails to promote growth in the same manner as com. lard, showing that the inefficiency of lard is not due to any heating during its prep. commercially. Heating butter fat for 2 1/2 hrs. with live steam does not destroy its growth-promoting power. Beef-fat facilitates growth but is not as efficient as butter fat, its content of the growth-promoting substance probably being so small that it becomes finally quant. inadequate. By subjecting butter- and beef-fat to fractional crystn., it has been found that the fats with high m. ps. are ineffective, the growth-promoting factor remaining in the mother liquors.

ALFRED P. LOTHROP.

ABNORMAL.

Persistence of glycogen in dogs during inanition. C. N. MICHAILESCO. Bucharest. *Compt. rend. soc. biol.* 76, 314-6(1914).—Twenty-four dogs of various ages and sizes were subjected to absolute fast for a period of 4-38 days, the detn. of glycogen being made by the Pflüger method. In the majority of cases glycogen disappeared completely from the organism of the smaller and younger dogs after a fast of 10-22 days. In the case of certain unusually vigorous animals glycogen had not disappeared after a fast of 31 days; glycogen disappeared completely, however, from a large dog of 18.7 kg. when the fast was prolonged to 38 days. In general, glycogen had always disappeared when the wt. of the animal became reduced by more than 40% of the original wt. as a consequence of fast.

H. S. PAINE.

Hypophysectomy and alimentary glucosuria. JEAN CAMUS AND GUSTAVE ROUSSY. Paris. *Compt. rend. soc. biol.* 76, 344-7(1914).—Expts. on young and full grown dogs showed that neither partial hypophysectomy extending to 1 or both lobes nor total hypophysectomy modified to an appreciable degree the tolerance to carbohydrates or the conditions governing the appearance of alimentary glucosuria. The limit of assimilation of carbohydrates was not appreciably affected by injection of concd. exts. of the entire hypophysis or of the anterior or posterior lobes in dogs which had been subjected to partial or total hypophysectomy. The results of these expts. (with respect both to spontaneous and to provoked glucosuria) on hypophysectomized animals are opposed to the views of Cushing and tend to diminish considerably the role attributed by him to the posterior lobe of the hypophysis as a regulator of carbohydrate assimilation.

H. S. PAINE.

Nutrient enemas. V. SCHEEL AND E. BEGRUP. *Ugeskrift Læger* 77, No. 13 (1915); *J. Am. Med. Assoc.* 64, 1804.—The findings testify to the good absorption and utilization of suitable nutrient enemas, thus sparing the reserves of the body. Milk and eggs irritated the rectum and were not absorbed properly even when combined with pancreas ext. The best results were obtained with meat amino acids. The 10 g. of N were given with 50-75 g. of grape sugar, fractionated in 2 or 3 enemas in the course of 24 hrs. About 250 cc. of fluid was found best for a single administration. The osmotic conc. was kept at about the same as that of the tissues to avoid irritation. More than 25 g. of sugar should never be given at one time. This treatment was kept up for nearly 3 weeks, supplying from 400 to 600 cal. daily. Most of the amino acids used were made by long-continued digestion of meat or milk by trypsin-erepsin.

ANDREW HUNTER.

Is epinephrine present in the blood at birth? S. CANNATA. *Pediatrics* 23, No. 4 (1915); *J. Am. Med. Assoc.* 64, 1883.—C. obtained constantly negative results in 31 healthy infants whose serum was tested for epinephrine by various technics.

L. W. RIGGS.

Differences in the digestion in adults and infants. J. F. McCLENDON. Minn. *J. Am. Med. Assoc.* 65, 12-4(1915).—The acidity of the stomach and reaction of the duodenal contents were measured by means of H electrodes. Indicator papers were calibrated so that approx. H-ion concs. may be detd. After a normal meal, the acidity of the adult stomach reaches its max. in from 2 to 3 hrs., the rise in acidity being more rapid the lighter the meal. The height to which the acidity rises varies with the individual. The H-ion conc. of the duodenal contents is 0.00000002 normal. This is slightly alk., since that of pure H₂O is 0.00000011 at 25°. The acidity of the infant's stomach rises slowly after the milk begins to leave it, and 4 hrs. after nursing may be the same as some normal adult stomachs. That of the gastric juice of the new-born is 0.005 normal. The acidity of the duodenal contents of the infant is 0.0008, and hence it is probable that both peptic and tryptic digestion take place in the intestine of the infant. Pepsin was always found and was apparently more abundant (active) than the trypsin.

L. W. RIGGS.

Forms of nitrogen in stools of infants. D. D. VAN SLYKE, *et al.* New York. *Am. J. Dis. Children* 9, No. 6(1915); *J. Am. Med. Assoc.* 65, 52.—Of the total N of infants' feces, from 50 to 70% was found as proteins and amino acids, 2.4 to 24% as free amino acids and from 3 to 37% as ammonia. Usually, though not invariably, the higher percentages of amino acid N were found in the looser stools, the more rapid passage through the intestine resulting in somewhat less complete absorption of these protein digestion products. The results show no evidence of antagonism between the processes of acid and ammonia formation, respectively, in the intestine. Urea was absent in 75% of the stools examd., and in the other 25% formed only 1 to 5.6% of the total N. Despite the care taken to keep the feces free from urine, the authors think that some of the positive results as to the presence of urea in the feces may have been due to the presence of traces of urine. As some of the watery stools contained no urea, it appears improbable that the intestine is capable of rendering significant assistance to the kidney, at least in the excretion of urea.

L. W. RIGGS.

The effect of functional activity upon the metabolism, blood-flow, and exudation in organs. J. BARCROFT AND T. KATO. *Proc. Roy. Soc. London (B)* 88, 54(1915).—Expts. on dogs. By measuring the rate of flow of blood in a vein from (1) striated muscle and (2) the submaxillary gland, and comparing this blood with arterial blood in respect to its O content and hemoglobin value, data were obtained of (a) the O used, (b) the rate of flow, and (c) the exudation of fluid. In the case of muscle, distinct retention of fluid was observed during stimulation. In the case of submaxillary gland, the lymph varies with the quantity of saliva secreted, and relatively to the rate of flow of saliva the increased O consumption and flow of blood rise for 2-3 hrs.

G. PATHOLOGY.

H. GIDEON WELLS.

Functional edema in frog muscle. M. BACK, K. M. COGAN AND A. E. TOWERS. *Proc. Roy. Soc. London (B)* 88, 544-8(1915).—In frogs in which the medulla and upper part of the spinal cord were left uninjured, but the brain was destroyed, and the lower part of the cord pithed, it was found that stimulation of the gastrocnemius invariably produced a distinct edema, the gain of wt. amounting in some cases to 12%. The edema was still evident 6 hrs. after stimulation, but the fluid was absorbed in less than 16 hrs.

A. T. CAMERON.

The activation of tetanus toxin. A. MARIE. *Ann. inst. Pasteur* 28, 1-5(1914).—Several million fatal doses of tetanus toxin can be neutralized by 1 g. of epinephrine, but the toxin is not neutralized in the presence of other substances contained in the suprarenal glands, or of exts. of liver or nerve tissue, or even of such a definite compound as lecithin. Because of the variability of various samples of lecithin, the effect of the

yolk of hen eggs upon tetanus toxin was tried. A quantity of the toxin 0.00001 as large as the dose which alone gave no stiffening of the inoculated foot of a mouse, gave a marked local tetanus when mixed with a minimal quantity of yolk of egg; 0.0000001 cc. of toxin added to this substance sufficed to give a 15 g. mouse a fatal tetanus in 8 days, while the control showed no apparent effects with 0.0001 cc. of the toxin, i. e., with a dose 10,000 times as large. This activation of tetanus toxin by the yolk of hen eggs occurs always in species very susceptible to the toxin, such as the mouse and the guinea pig. With the dog, which shows a marked natural immunity to tetanus toxin, doses of the toxin much inferior to those which produce tetanus by intramuscular injection cannot be rendered active.

GEO. T. CALDWELL.

Ricin. III. *Hypersensibility to ricin.* E. ALLAIRE. *Ann. inst. Pasteur* 28, 605-7(1914).—Ricin, like abrin, produces after incubation an ocular inflammation in man when placed in the conjunctiva. The author states that he reacts violently without incubation even to traces of ricin. Symptoms similar to those of hay-fever appear as a result of the inhalation of the small amt. of ricin liberated by the removal of a stopper from a bottle containing the dry prepn. An intense itching is produced by the application of a trace of a glycerinated soln. of ricin to the back of the hand. This hypersensibility is specific and seems to be acquired.

GEO. T. CALDWELL.

The anaphylactic reactions produced by the albuminous substances of the crystalline lens. V. MORAX AND J. BOLLACK. *Ann. inst. Pasteur* 28, 625-38(1914).—An animal sensitized by the injection of the albuminous substances from the crystalline lens of a given foreign species reacts nearly always to a second injection of crystalline lens from this same species, more often to a second injection from a different species and practically never to a subsequent injection of serum from the same species. An animal may not react to a subsequent injection of crystalline lens of its own species if it has been sensitized by an injection of crystalline lens of a different species. So far as anaphylactic reactions are concerned, the crystalline lens seems to possess special properties, differing from those of all other organs and of the serum. It is possessed with a true organ specificity, since the animal sensitized to crystalline lens of any one species does not react to the serum of the same species. On the contrary, it is destitute of all species-specificity, since animals react to crystalline lens from whatever species they come. The properties of organ extracts may be due to the serum which they always contain. The vascular crystalline lens of the embryo may possess an action analogous to that of the sera of the animals of the same species. The organ-specificity is probably a secondary property dependent upon the special biological conditions of this organ in the adult.

GEO. T. CALDWELL.

Ricin. V. The fate of ricin (toxin and agglutinin) during the germination of the castor-bean. H. AGULHON. *Ann. inst. Pasteur* 29, 237-48(1915).—The ricin toxin disappears slowly during the germination of the castor-bean; it remains localized in the albumin; one can find very little of it in the plantule; its disappearance coincides with the transformation of the albumin. The same is true concerning ricin agglutinin; this seems to disappear more quickly proportionately than the toxin. During one short period of the growth, a hemolysin appears, together with the agglutinin, both in the plantule and in the albumin; this hemolysin is thermostable, destroyed by alcoholic pptn. and unaffected by anti-ricin serum. Whether this hemolysin bears any relation whatever to the disappearance of the agglutinin is not known. At a certain time in the germination, a substance toxic for mice, resistant to boiling and not precipitated by alc., appears in the plantule; its nature has not yet been detd., but everything seems to indicate that it behaves as an alkaloidal poison.

G. T. C.

The immune bodies occurring in anti-rinderpest serum and the variations occurring in the serum proteins of animals during rinderpest and during immunization and

hyper-immunization. PERCIVAL HARTLEY. *Memoirs Dept. Agric. India, Vet. Series* 1, No. 4(1915).—H. finds that the active bodies are similar to or are associated with the euglobulins. They are insol. in half-satd. $(\text{NH}_4)_2\text{SO}_4$ soln. and in satd. salt soln., and can be completely pptd. by dialysis with running tap water. By drying any of the above ppts. *in vacuo* over H_2SO_4 they can be obtained in the form of a powder. Their activity is lessened by the presence of HCl even in very low concns. The effect of alkalis is not so pronounced. Disease is accompanied by decreases in the total heat-coagulable protein, in the globulins (insol. in half-satd. NH_4Cl soln.), and in the protein insol. in satd. salt soln. The decrease in the last-named group is the most striking. On immunization an increase of the above proteins takes place. The increase of the globulins is shown to be almost entirely in the portion insol. in satd. salt soln. Hyper-immunization is accompanied by a more potent serum and a further increase in the same group of proteins. The potency of the serum is lowered and the quantity of the last-named group of proteins is decreased on repeated bleeding of the hyper-immunized animals; these factors are again increased by further injection of virulent rinderpest blood. The article is supplemented by a large number of charts. H. W. DAUDT.

Observations on the use of the Abderhalden reaction with normal and pathological human serums. ELLISON L. ROSS AND H. D. SINGAR. Illinois State Psychopathic Inst. *Arch. Intern. Med.* 15, 724-32(1915); cf. *C. A.* 9, 92.—Substrates prep'd. from certain human tissues contain material which is digested by enzymes present in normal human serum. This material can be washed out by boiling repeatedly with slightly acidified H_2O . The H_2O used for washing contains material that can be digested by normal serum enzymes. Brain substrate which has been washed until it no longer gives positive reactions with normal serum may still be digested by the serum of general paralytics. The material which undergoes lysis can be removed by further washing. The material thus removed is digested by normal serum in as great a degree as by that of general paralytics. The difference in the action of sera from normal persons and from general paralytics upon brain substrate appears to be quant. rather than qual. Expts. on the lysis of tissue substrates by pathological sera are of no value in permitting conclusions as to the seat of the lesion. I. GREENWALD.

The factors of coagulation in primary pernicious anemia. CECIL K. DRINKER AND SAMUEL H. HURWITZ. Peter Bent Brigham Hosp., Boston. *Arch. Intern. Med.* 15, 733-45(1915).—"Prothrombin is diminished slightly in all cases of pernicious anemia. This diminution is not great and is unimportant if active regeneration is in progress. Antithrombin and fibrinogen are normal even in the presence of very low cell counts. In one case in which there has been pronounced diminution in prothrombin, platelet counts have been strikingly low, and the picture throughout has been that of fairly complete aplasia." (Cf. *C. A.* 9, 1934). I. GREENWALD.

The origin of the protein of nephritic urine. A. L. CAMERON AND H. GIDEON WELLS. Univ. Chicago. *Arch. Intern. Med.* 15, 746-53(1915).—"A series of expts. by the anaphylaxis method gave no evidence of the existence of antigens in either urine or kidney distinct from each other or from the antigen of human serum. This result does not answer the question of the origin of urinary protein, but merely indicates the inadequacy of the anaphylaxis method for the solution of the problem." I. G.

Studies in renal function with special reference to non-protein nitrogen and sugar concentration in blood, phenolsulfonephthalein elimination and blood pressure. ARTHUR H. HOPKINS AND LEON JONAS. Univ. Penna. *Arch. Intern. Med.* 15, 964-73(1915).—High-protein feeding in nephritis, particularly in the chronic interstitial type, increases the amt. of non-protein N (N. P. N.) in the blood. Retention of N is generally accompanied by a low phenolsulphonephthalein (P. S. P.) excretion and by hypertension. Chronic passive congestion does not lead to an increase in the N. P. N.

of the blood but may diminish the excretion of P. S. P. A slight hyperglucemia occurs in many nephritics with high blood pressure and is frequent in those with retention of N and impaired P. S. P. excretion. I. GREENWALD.

A study of general and localized effects of intravenous injections of colloidal copper and casein in cases of human cancer. C. B. McCLURG, W. O. SWEEK, H. N. LYONS, M. S. FLEISHER AND LEO LOEB. St. Louis. *Arch. Intern. Med.* 15, 974-1013(1915).—An extended report not suitable for abstracting. I. GREENWALD.

The relation of uric acid to gouty attacks. AMY L. DANIELS AND FRANCIS H. McCRUDDEN. Peter Bent Brigham Hosp., Boston. *Arch. Intern. Med.* 15, 1046-52(1915).—In 2 cases of gout, the uric acid concn. in the blood was not above the normal and was not altered during gouty attacks. The excretion of uric acid was also unaffected at these times. Such attacks appeared during the period of atophan administration when the concn. of uric acid in the blood had been markedly diminished. I. G.

Urobilin in the stool—an index to blood destruction. OSWALD H. ROBERTSON. Mass. Gen. Hosp. *Arch. Intern. Med.* 15, 1072-8(1915).—An increased amt. of urobilin in the feces was found in 11 cases of pernicious anemia (except during remissions) and in congenital hemolytic jaundice, malaria and 1 case of secondary anemia, all of which showed clinical evidence of increased blood destruction. Cases of leucemia, secondary anemia, chronic passive congestion, pneumonia with jaundice and diseases of the liver all showed a urobilin output within the limits found in normal individuals. Those cases in which evidence of blood destruction was most marked had the highest urobilin content in the feces. None of the cases with normal urobilin showed evidence of hemolysis. The test is believed to be of considerable value. I. GREENWALD.

Further studies on the relation of diet to transmissible tumors. J. E. SWERT, ELLEN P. CORSON-WHITE AND G. J. SAXON. Am. Oncologic Hosp., Philadelphia. *J. Biol. Chem.* 21, 309-18(1915).—Rats fed on a growth-inhibiting diet (cf. Osborne and Mendel, *C. A.* 7, 364, 635) gave a smaller % of takes and metastases and a larger proportion of retrogressions after inoculation with the Flexner-Jobling carcinoma than did those on a normal diet. The administration of cholesterol subcutaneously (on or at a distance from the tumor) or by mouth increased the proportion of takes and metastases in both sets of animals, but did not change the relation between the results obtained with the 2 diets. Treatment inhibiting tumor growth is also apt to inhibit spermatogenesis. I. GREENWALD.

The mixed antigen method of detecting vegetable proteins. A. ZADE. Jena. *Centr. Bakt. Parasitenk. II Abt.* 42, 712-8(1915).—A method of detecting seed protein is as follows: An ext. of 6 different species of seeds was made with physiol. NaCl soln. and injected into an animal. The resulting antiserum produced a max. ppt. only when mixed with the ext. of all 6 seeds. To det. the species of a seed, the ext. of 5 of the seeds with which the animal was immunized was mixed with the antiserum. After the ppt. was formed, the ext. of the unknown seed was added. If an additional ppt. was formed, it was the 6th protein with which the animal was immunized. If no additional ppt. was formed, the unknown ext. was one of the 5. By varying the combinations, the species of the seed could be detd., if it was one of the species with which the animal was immunized. JULIAN H. LEWIS.

Therapy of calcium chloride in tuberculosis. BRASLY. *Indianapolis Med. Journal* (January); *Cincinnati Med. News* 2, No. 4, 55(1915).—Preliminary report concerning the intravenous injection of CaCl_2 in tuberculosis. Subsequent examination of subjects succumbing to the disease, revealed scantiness of C deposits, the quantity of same bearing a direct ratio to the progress attained by the disease. Clinical considerations constitute the rest of the article. SIMON MENDELSON.

The tuberculin reaction in swine. LINDNER. *Arb. kais. Gesundh.* 48, 293-302 (1914).—The normal temp. of 3 mos. old swine ranges between 39.0° and 40.0°. Subcutaneous injections of 0.1 to 0.3 cc. of tuberculin sometimes causes a rise in temp. to 41.0°, even in normal animals. A rise of temp. of 1.0° must be regarded as a positive reaction in swine after an injection of tuberculin. Of 16 positively tubercular animals all gave typical reactions after subcutaneous injection. The max. temp. was reached in 10-16 hrs., the 40.0° mark often being exceeded in 6 hrs. The administration of glycerol produces an intracutaneous reaction which is slightly different in degree and duration from that produced by tuberculin. For intracutaneous use glycerol-free tuberculin is recommended.

W. A. PERLZWEIG.

Fever studies. I. The specific hypersensitiveness of the heat centers in sensitized animals. MASAKAZU HASHIMOTO. Univ. Vienna. *Arch. exp. Path. Pharm.* 78, 370-93(1915); cf. following abstr.—While the intracerebral injection of small amts. (0.2 cc.) of horse serum or 0.9% salt soln. is without effect upon the body temp. of normal animals, 0.2 cc. horse serum causes a typical temp. fall in sensitized animals; this takes place at the close of the injection and reaches a max. (up to 3°) after 1-1.5 hrs. The duration and amt. of the decrease of temp. is, to a certain degree, dependent upon the amt. of serum injected. There is also a strong parallelism between the sensitization period and the intensity of the reaction. It occurs slightly after 3 days, considerably from the 6th to 8th day, reaches a max. from the 14th to 20th day and is yet present after 45 days. The amt. of serum which is active when injected intracerebrally (0.02 to 0.2 cc.) has no effect when given intravenously. The same effect is obtained by the use of 2-3 cc. intravenously. By the intracerebral addition of horse serum near the thermal center in smaller doses (0.0005-0.01 cc.) there occurs a more or less pronounced fever (0.8 to 1.35°); the same effect is produced by intravenous injection of 10 to 30 times that amt. (0.005 to 0.3 cc.). The fever begins in about 1/2 hr., reaches a max. at 1.5-2 hrs. and lasts 2-3 hrs. These temp. changes can be completely suppressed by the so-called "Zwischenhirn" puncture of Citron and Leschke (*C. A.* 8, 2747). The changes produced by intracerebral injections take place only if the proper antigen is injected into the sensitized animal; this reaction is, therefore, specific. They are entirely lacking in immunized animals. This shows that it is a typical anaphylactic phenomenon.

The effect of theobromine sodium salicylate in acute chromate nephritis. JAMES P. O'HARE. Harvard Med. School. *Arch. Intern. Med.* 15, 1053-8(1915).—The administration of theobromine sodium salicylate to rabbits with chromate nephritis appears to hinder the excretion of H₂O and phenolsulfonephthalein and possibly that of N. In severe or moderately severe types, such treatment usually shortens the life of the animal; in mild cases it may prolong it.

I. GREENWALD.

I. ZOÖLOGY.

R. A. GORTNER.

The adaptability of amphibia to the surrounding liquid medium by variations of the osmotic pressure of their body fluids. VI. The time in which osmotic regulation takes place. BRUNO BRUNACCI. *Atti accad. Lincei* 24, I, 272-6(1915); cf. *C. A.* 7, 2802, 3475; 9, 1944.—The expts. were carried out in solns. at room temp. (about 12°).

The frogs were first kept in soft water and then transferred to a hypertonic Ringer soln. (1.0% NaCl, etc.) and some to a weaker Ringer soln. (0.9% NaCl, etc.). 8-9 hrs. were required for the animals to raise the level of the concn. of their internal liquids to somewhat above that of the external soln. 6-7 hrs. were not sufficient. As was stated previously the osmotic regulation of the frog in the first hrs. of the adaptation takes place at the expense of the electrolytes, while during the following days it is due to osmotically active organic substances formed within the organism itself. The lymph of the sacs which is small in amt. in the first 6-7 hrs. increases later. The urine is formed following the increase in lymph. When the frogs were transferred to running soft water after remaining some days in the hypertonic solns. there was no increase in the lymph in the lymph sacs after 6-7 hrs. In general it was found that it took less time to increase the mol. concn. of the internal liquids of the animal than it took to reduce this greater conc. to that present at first. Since B. observed that frogs taken from a different locality, even after being kept for some days under the same conditions, showed a greater mol. concn. of their blood, he suggests that it is possible that osmotic characteristics acquired from the external medium become fixed in the blood to some extent.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

The development of the technic of the microscopic examination of stockfoods at the federal agricultural experiment stations, during the last twenty-five years, especially with reference to compressed stockfood cakes. F. F. BRUYNING. *Wageningen. Pharm. Weekblad* 52, 273-93, 309-33(1915).—A review. P. v. D. M.

The determination of water in spices. L. VAN ITALLIE, M. KERBOSCH AND A. P. OLIVIER. *Leyden. Pharm. Weekblad* 52, 205-16(1915).—Of the various methods for the detn. of water in spices, only the distn. method gives accurate results. For this method, toluene or xylene is preferable to benzine, which yields low results, and to paraffin, which yields high results. The numerical data cannot be briefly abstracted. P. v. D. M.

Microscopy of cinnamon and its adulteration. P. POOTH. *Mikrokosmos* 16, 9-12(1915).—P. enumerates a number of the commonest adulterants and microscopical methods of detecting same. Two illustrations (drawings) are appended. C. A. N.

Unfermented grape juice. A. MCGILL. *Lab. Inland Rev. Dept., Ottawa, Canada, Bull.* 307, 19 pp.(1915).—An examn. was made of 107 samples collected throughout Canada during the last 3 months of 1914. The Canadian legal requirements for grape juice are: d_{40} must be between 1.0400 and 1.1240; total sugars 7-28% (stated as reducing sugars); ash 0.20-0.55 g. per 100 cc.; P_2O_5 15-70 mg. per 100 cc.; alc. must be less than 2% (vol.). With very few exceptions these limits are met by the samples reported; the exceptions indicate additions of sugar or water or both. E. J. C.

Determination of boric acid and its compounds in extracts of tomatoes and other preserved food. NICOLÁS CAMUS. Buenos Aires. *Anales soc. quim. Argentina* 2, 123-30(1914).—The method which is usually employed for the detn. of H_3BO_3 in food products and which consists in incinerating the initial material (after previous addition of alk.), extg. the ash with HCl and H_2O and evapg. the filtered acid soln. in the presence of turmeric paper is difficult of application to food products, such as canned tomatoes, which contain a large amt. of salts (usually NaCl), inasmuch as the latter crystallize upon the turmeric paper during evapn. of the filtered acid ext. and interfere to a varying extent with the development of the characteristic reddish coloration. This difficulty may be obviated by extg. the free H_3BO_3 with acetone (in which NaCl and the

other salts present are insol.); it is possible by this means to make an approx. quant. detn. which is sufficiently accurate when the amt. of H_2BO_3 present varies between the limits of 0.00001–0.002 g. The modified method consists in taking, 5 g. tomato conserves in a 30 cc. porcelain crucible, adding several drops of a 20% NaOH soln., mixing well, heating gently over a flame until the H_2O has evapd. and then incinerating at a dark red heat (so as to prevent fusion of salts). It is only necessary that organic material be sufficiently destroyed so that it does not cause coloration of the ext. The ash is finely pulverized and is then (after being moistened with several drops conc. HCl in order to liberate H_2BO_3) extd. successively for 1–1½ min. at boiling temp. on the H_2O bath with two 20–25 cc. portions of pure Me_2CO . The combined Me_2CO exts. are filtered and evapd. to dryness and the residue is dissolved in 3 cc. very dil. HCl (1 cc. HCl of 1.19 sp. gr. in 100 cc. H_2O); the latter soln. is then evapd. to dryness in the presence of two 1×15 cm. strips of recently prepd. turmeric paper. The Me_2CO employed should be colorless and should distil entirely at 56–7° without leaving a trace of colored residue; it should be free from MeOH or EtOH (so as to prevent the formation and loss by volatilization of Me and Et esters of H_2BO_3). It is possible, by means of simultaneous tests on standard solns. executed under identical conditions, to det. approx. the amt. of H_2BO_3 present from the shade and intensity of coloration of the turmeric strips. The intensity of the coloration diminishes rapidly (especially in damp weather); it is also necessary to avoid the presence of NH_3 vapors. The turmeric reagent paper should be prepd. by soaking white filter paper in an alc. soln. of pure curcumin and drying the former in an atm. free from acid or NH_3 vapors; when kept in closed bottles (preferably in the dark) the sensitiveness of this reagent paper is preserved for several days. The shade of coloration obtained with a given amt. of H_2BO_3 varies from a rose to an intense red according to the conc. of the curcumin solns. used in prepg. the test papers. When the latter were prepd. from a 0.01% curcumin soln. a pale rose coloration was produced in the presence of 0.0005 g. H_2BO_3 , while subsequent application of dil. NH_4OH (1 vol. NH_3 to 2 vols. H_2O) produced a sky-blue coloration. Test papers prepd. from a 0.08% curcumin soln. gave a red coloration with the same amt. of H_2BO_3 , while NH_3 caused the red coloration to change to intense blue. Test papers prepd. from a 0.5% curcumin soln. gave, with the above amt. of H_2BO_3 , a dark red coloration which changed to black when treated with NH_3 . A 0.05% curcumin soln. is most suited for amts. of H_2BO_3 varying between 0.00002–0.001 g. For each conc. of curcumin soln. the coloration produced by increasing amts. of H_2BO_3 reaches a max. intensity which represents the limiting amt. of H_2BO_3 which may be detd. by this method of color comparison. A tabulation is given of the intensity and shade of the colorations produced with definite amts. of H_2BO_3 and test papers prepd. from curcumin solns. of various concs. In order to have comparable conditions it is necessary to use test papers of the same dimensions, inasmuch as the intensity of coloration is a function of the area of the surface of the paper. H. S. P.

Some important constituents in the fruit of the Osage orange. J. S. MCHARGUE. *J. Ind. Eng. Chem.* 7, 612–3(1915).—Analytical. The pulp and seed contain constituents which might be of value to feed, fertilizer, oil and resin industries. I. M.

The detection of phytosterol in animal fats according to the Bomer acetate test with separation of the sterol by digitonin precipitation. B. KÜHN, F. BENGEL AND J. WERWERINKE. *Stettin. Z. Nahr.-Genussm.* 29, 321–9(1915).—The methods hitherto proposed (*C. A.* 8, 536; 1315, 3246; 9, 1079) have been further modified in that the sterol digitonide is pptd. directly in the mixed fatty acids without mechanical stirring and the sterol acetate is pptd. directly from the acetylation mixt. by treatment with 4 vols. of 50% EtOH. Treat the fatty acids from 50 g. of the fat in a 200 cc. beaker with 25 cc. of a 1% soln. of digitonin in 96% EtOH and heat on a closed

steam bath at 70° for $1\frac{1}{2}$ to $2\frac{1}{4}$ hr. until the ppt. seps. out, stirring occasionally during this time. Dil. the mixt. with 15–20 cc. of CHCl_3 , filter by means of suction, and wash the ppt. first with CHCl_3 , and then with ether until free from fat. Dry the ppt., boil with 3–5 cc. of acetic anhydride for 5 min. and then dil. the hot mixt. with 4 vols. of 50% EtOH. Sep. the crystals by filtration and recrystallize from ether in the usual way. The method will permit the detection of 1% of cottonseed oil in lard.

A. F. SEEKER.

A proposed new method for detecting the watering of milk. REMO CORRADI. Palermo. *Boll. chim. farm.* 53, 399–400(1914).—C. discusses the reply (C. A. 9, 1515) of E. Comanducci to C.'s previous criticism of Comanducci's proposed method for the detection of watering of milk. C. again contends that the average values of 5.46% lactose and $2^\circ 54'$ rotatory power assumed by Comanducci for pure milk are not correct inasmuch as the latter was not justified in rejecting certain data in obtaining these average values. C. points out that a decrease in rotatory power due to watering may be readily compensated by the addition of glucose or sucrose (which is by no means a new practise in adulteration).

Evaporated milk. A. MCGILL. Lab. Inland Rev. Dept., Ottawa, Can., *Bull.* 305(1915).—Analyses (for total solids and fat) of 178 samples of evapd. milk collected throughout Canada.

P. J. DONK.

Condensed milk. A. MCGILL. Lab. Inland Rev. Dept., Ottawa, Can., *Bull.* 304(1915).—Report on analyses of 200 samples of condensed milk collected throughout Canada, giving values for sp. gr., total solids, ash and fat.

P. J. DONK.

The influence of the age of cheese on the fat content. K. SCHERINGA. *Pharm. Weekblad* 52, 238–45(1915).—The pressing of the curd into cheese can produce a very decided irregularity in the distribution of fat in the cheese. If a cheese be allowed to stand at high temp. these irregularities will disappear. Furthermore, after some time an entirely different condition from the original will usually be found to prevail, due to salt and fat displacement, so that on repetition of the investigation great differences can be found between samples from the same location. As sample a pyramid should be taken, preferably from more than one point. It is suggested that a limit be set for the fat content, calcd. on the dry material, after subtraction of the ash content.

P. J. DONK.

Studies upon the microscopy of flour and bread. C. POSENER. Berlin. *Z. Nahr.-Genussm.* 29, 329–37(1915).—P. indicates the well-known characteristics of cereal and potato flour when examd. under the microscope both by ordinary and by polarized light, showing also how these characteristics are altered by moist heat. He advocates the use of selective stains for ascertaining the nature of mixed flours and of bread prepared from them. For staining purposes mix a little of the flour or a thin paste of bread prepared by rubbing with water in a mortar, with the staining soln. and wash out the excess of water by centrifuging. Mounts may be stained by rubbing to a thin paste on a slide with a drop of the staining soln. and washing under the cover glass with water. The Ehrlich-Biondi triacid mixt. leaves wheat starch uncolored, but stains cellulose green, aleurone grains red, and pseudo-nucleins blue-green. Naphthalene blue leaves starches uncolored, cell walls and proteins becoming dyed. Methylene blue stains cereal starches a light blue, potato starch dark blue, the stain being easily washed out of cereal starch but not out of potato. A "black-white-red" stain evidently containing Congo red employed by the (Berlin?) Institute für Getreideverarbeitung

stains rye starch blackish, protein pink or red, while potato starch remains colorless. Other useful selective stains are giesma soln., thionine, cresyl violet and gentian violet.

Kansas flours. Chemical, baking and storage tests. C. O. SWANSON, J. T. WILLARD AND L. A. FITZ. *Kansas Agr. Expt. Sta. Bull.* No. 202, 135 pp.(1915).—The bull. is divided into 4 parts. In Part I are described the equipment and the method used in making the baking tests. The method is in a stage of development. In Part II are given the results of the baking tests and the chem. analyses of 35 com. flours collected from Kansas mills. In addition chem. analyses of 21 wheats are given, which represent the wheats from which the flours were made. The flours were classified into 3 grades; short patent, long patent and straight. A close relation is shown between acidity and P, both total and water-sol. There is also a relation between ash and acidity. The water added in tempering influences the moisture content of the flour more than the moisture originally present in the wheat. It is shown that the protein content of wheat has a pronounced effect on the protein content of the flour. The method of milling influences acidity, ash and P content of the flour more than any variation of these constituents in the wheat. In Part III are given the chem. comp. and baking tests on flours from 2 sets of mill streams. In Part IV is given the report of 2 seasons' work on the effect of conditions of storage on flour, using bleached and unbleached flour.

B. E. BROWN.

Note on the estimation of carbonic acid in self-rising flours and baking powders. T. MACARA. *Analyst* 40, 272-5(1915).—Since in the analysis of baking powder and similar preps. no account is taken of the CO_2 liberated from the excess of NaHCO_3 by the acid in the food and the heat of baking, M. suggests that the "apparent" available CO_2 be detd., and he defines this as the amt. of CO_2 liberated on boiling with water for 30 min. He suggests the following method: 2-5 g. of the baking powder (or 10 g. self-raising flour) are transferred to a dry liter flask, A. Four or 5 pieces of pumice are added, and the flask is closed with a 2-holed stopper carrying a dropping funnel and an outlet tube leading to the bottom of a second liter flask, B. Flask B is also fitted with a 2-holed stopper through which are passed the tube from A, and a safety funnel; it contains 50 cc. satd. $\text{Ba}(\text{OH})_2$ and 100 cc. well boiled, cooled water. The seal of the safety funnel is closed with $\text{Ba}(\text{OH})_2$ soln. colored with phenolphthalein. 100 cc. alc. are run into A and the mixt. shaken to break any lumps. 100 cc. water are then added and the mixt. shaken again. The absorption flask should also be shaken if any CO_2 appears to be passing into it. 100 cc. liquid paraffin are added to A and the mixt. is heated to brisk boiling, the boiling being continued for 15 min. Without stopping the operation, 400-500 cc. boiling water are added, and the boiling continued for 15 min. The absorption flask B should be kept well shaken during the earlier part of the process. It is cooled in a basin of water when it begins to heat. At the end of 30 min., flask B is disconnected, the inlet tube closed, and the contents cooled in running water, if necessary. A small funnel is then inserted in the inlet tube, and the excess of $\text{Ba}(\text{OH})_2$ neutralized with 20% HCl to slight acid reaction with phenolphthalein. 0.5 N NaOH is then run in to slight alkalinity, and the flask is well shaken to absorb any CO_2 which may have been liberated. The stopper is then removed, and the contents of the safety funnel washed into the flask. Then the soln. is carefully neutralized with 0.5 N or 0.1 N HCl . Methyl orange is added, and titration completed.

P. B. DUNBAR.

The detection of the addition of potato to war bread. A. LINGELSHEIM. Breslau. *Z. Nahr.-Genussm.* 29, 361-8(1915).—Raw potato starch can readily be detected in cereal flour when seen under the microscope both by its well-known form and by its behavior under polarized light. The cooked and rolled potato product called "Walz-

mehl" is characterized by the mottled appearance of the rounded or somewhat polygonal masses of starch about 300μ in size, which under polarized light show strongly illuminated borders. It is also to be recognized by the cork cells occurring in fragments of the potato peel, the lumen of which measure $60-100\mu$. For detecting potato products in the finished bread remove 5 pieces about the size of a pea from different parts of the loaf and soften each separately by soaking in water. Prepare a separate mount of each by placing a piece about one cmm. in size upon a slide and pressing it down very thin under the cover glass. Exam. under a magnification of $70-80$ by polarized light. Strongly illuminated, irregular, oyster-shaped or oval particles containing dark lines or patches indicate potato starch. If "Walzmehl" is present it is indicated by the large ($80-300\mu$) starch cells of the potato, these being shown in sharp bright outline under polarized light. By mounting the bread in dil. NaOH the cork cells also become plainly visible under polarized light. The process of baking destroys the feeble optical activity of the cereal starches but impairs that of potato starch to a much less degree. The cell walls of the aleurone layer and the parenchyma of the endosperm of cereals also become visible under polarized light, the former being gradually destroyed if the mount be made in dil. NaOH. These elements are not readily confused with those of potato preps. By comparing the appearance of the unknown with that of amounts prepared from bread of known potato content an estimate can be formed of the amt. of potato present in the sample under exam. Illustrations are given. A. F. SEEKER.

Importance of potato-meal as a food. KARL LANZ. Cüstrin-Neustadt. Z. *Spiritusind.* 38, 199-200(1915).—A review of the uses of potato-starch and products derived therefrom. L. W. HAAS.

Detection of wheat and potato flour in bread. BODINUS. *Pharm. Ztg.* 60, 110 (1915).—Triturate about 3 g. of the finely powdered sample, previously dried at $60-70^{\circ}$, with 10 g. H_2O , then transfer to a boiling mixt. of 200 cc. H_2O and 1 cc. 50% KOH soln. and boil in a porcelain evapg. dish during 5 min. with const. stirring. After allowing to stand a short time, decant the hot liquid carefully, leaving about 20 cc. behind. Centrifuge the latter and subject the solid matter to a microscopical examn. It is suggested that permanent preps. of pure wheat and potato flour mixts. be made for comparison. W. O. E.

Decision of the Kaiserlichen Gesundheitsamt on the use of potato products in bread-making. Arb. kais. Gesundh. 48, 595-606(1915).—A bread prepared from rye flour with additions of potato products (potato flakes, "Walzmehl" (a cooked and rolled potato product) and potato starch) as high as 20% was not inferior to pure rye bread in appearance, color consistency, odor, and taste. Total food value (cal.) was only slightly less than that of pure rye bread. It is possible to increase the water content. H. A. PIPER.

Ether-soluble matter in the nitrogen-free extract of feedstuffs. J. B. RATHER. J. Ind. Eng. Chem. 7, 613-5(1915).—Twelve samples were studied. The N-free ext. contained from 0 to 3.84% ether-sol. material, averaging 1.49%. Six hays and 6 excrements from them contained 2.72-12.39%, av. 5.97%. In the concentrates this ether-sol. material consisted on an average of 2% unsaponified and 98% free fatty acid while in the hay and excrements the av. compn. was 3% unsaponified, 30% fatty acids and 67% saponified residues. ISADOR MILLER.

The determination of the total amount of cottonseed hulls in cottonseed cake and meal. P. S. TILSON. Houston (Tex.) Labs. Paper read before The National Oil mill Superintendents Assoc., Galveston, Tex., *Separate*(1915).—The method is based on the crude fiber content of pure cottonseed hulls and hull-free meal, the average for the former having been found to be 54.39%, for the latter 2.46% on an oil- and moisture-free basis. Det. the moisture, oil and crude fiber contents of the sample

by the usual methods. Next calc. the factors 54.39 and 2.46 to the basis of the moisture and oil contents. The total amt. of hulls can then be calcd. algebraically. Results correct within 1% of the total hull content of cottonseed cake or meal can be obtained.

BERNARD RAYMUND.

Feeding experiments with fattening swine, making comparison of dried yeast, granulated blood and extracted fish meal. KLEIN. *Milchwirtsch. Zentr.* 44, 97-103 (1915).—Three lots of swine were fed for three separate periods. The ration for each group contained barley, barley bran and potatoes; the first contained skim milk and dried yeast; the second, one-third as much skim milk and in addition granulated blood; the third, no skim milk but some fish meal. The first group gained more wt. than the second, and the second more than the third.

L. L. VAN SLYKE.

Dried yeast as food for farm stock. CHARLES CROWTHER. *Univ. Leeds. Brewers J. (London)* 51, 286-8(1915).—Dried yeast has proved a safe food for cows, pigs and calves. For cows, it is not to be strongly recommended, since they show a special aversion to its bitter taste. It has proved a good food for pigs, having given results markedly better than those obtained with an equal wt. of wheat "sharps." Dried yeast keeps well, and on mixing with other meals and water, may be kept for some time without objectionable fermentation taking place. The value of the manurial excreta may be expected to be as high as that of any other foodstuff commonly used on the farm. Although the experience with dried yeast has been favorable, there is no reason to believe that dried yeast possesses special medicinal or dietetic virtues which any other highly digestible food, rich in albuminoids, might not be expected to possess.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Solubility of calcium carbonate and magnesium carbonate in water free from carbon dioxide, with a consideration of the salt content and organic substances. E. GOTHE. *Chem. Ztg.* 39, 305-7, 326-7(1915).—The solubility of CaCO_3 in CO_2 -free H_2O varies slightly, averaging 31.0 mg. per l. The solubility of MgCO_3 varies much more widely, averaging 94.4 mg. per l. The solubility of CaCO_3 and MgCO_3 is raised by chlorides, nitrates, and sulfates of the alkalis and is lowered by carbonates. The chlorides, nitrates, and sulfates of the alk. earths lower the solubility. Ca and Mg bicarbonates are greatly influenced in their solubility by organic matter, especially in the presence of neutral salts of the alkalis.

W. W. HANFORD.

Absorption of chlorine as criterion of quality of waters. E. A. ZALESKII AND N. A. EL'MANOVICH. *J. Russ. Phys. Chem. Soc.* 46, 1270-83(1914).—When chlorinated lime (a) is used for the purification of H_2O for drinking purposes, the alkalinity and the temp. of the H_2O exercise a great influence on the amt. of Cl it is capable of absorbing. Hence the authors treat the H_2O with $\text{Ca}(\text{OH})_2$ and (a), successively boil and cool the mixt. for a definite length of time, and, after adding $\text{KI} + \text{HCl}$, det. the unabsorbed Cl by titrating the liberated I with $\text{Na}_2\text{S}_2\text{O}_3$. Numerous tables illustrate the results.

H. M. GORDIN.

Representation of the results of analysis of natural waters. P. P. VON VEIMARN. *J. Russ. Phys. Chem. Soc.* 46, 752-3(1914).—The expression of the analytical results of water analysis in terms of salt contents is incorrect, since many of the salts (e. g., $\text{Ca}_3(\text{PO}_4)_2$, CaCO_3 , etc.) do not exist in the water on account of insolubility. On the other hand, the representation of the data in terms of ions is to many insufficiently lucid. The author, therefore, proposes an interpretation in salt terms of the compn. of the dry residue which actually contains these salts in the form represented.

H. M. GORDIN.

Detection and iodometric determination of nitrous acid in polluted waters. L. W. WINKLER. Budapest. *Z. Nahr.-Genussm.* 29, 10-7(1915).—On adding KI in

acid soln. to a water containing nitrites, free I is liberated and the sepn. of I goes on indefinitely as long as there is dissolved O present. If the I is titrated after a given period of time, the nitrite content may be detd. with a relatively great degree of accuracy when the nitrite content is less than 0.3 mg. N_2O_5 per l. For larger amts. the author's iodometric bicarbonate method (*Chem. Ztg.* 23, 454(1899) and 25, 586(1901)) is applicable. Preliminary expts. were run to det. the amt. of I liberated after definite periods of time. To 100 cc. portions of nitrite-free H_2O , satd. in glass-stoppered flasks with air at 20°, known amts. of $NaNO_2$ were added, and 0.2 g. pure KI and 5 cc. of 25% H_3PO_4 added to each flask. The flasks were allowed to stand 3, 6, and 24 hrs. in the dark and the liberated I titrated at the end of each period. The I set free was not proportional to the HNO_2 present. A table was constructed from the results of the titrations to show directly mg. N_2O_5 corresponding to any titration of 0.02 N thiosulfate from 0.05 cc. to 10 cc. The detn. on unknown waters is carried out in the same way as the above expts., titrating preferably after 24 hrs. Small amts. of iron and organic matter do not interfere, but when in larger amts. they should be removed.

L. D. ELLIOTT.

Physical and chemical constants of mineral waters. F. BORDAS. *Ann. fals.* 7, 387-407(1914); through *J. Chem. H. S. BAILEY.

Chemical composition of the water of the "Kuvak" springs and the probable cause of their pollution. P. P. VON VEIDMARN. *J. Russ. Phys. Chem. Soc.* 46, 746-52(1914).—At present there are no human habitations in the neighborhood of the springs; the fact that the H_2O is polluted with org. matter seems to indicate that refuse from former times must exist somewhere nearby. The physical properties are satisfactory but a chem. exam. shows, however, that the H_2O contains NH_3 and nitrites, and must be regarded with suspicion if it is to be used for drinking purposes. H. M. GORDIN.

Hydrological evidence of soft water. E. PRINZ. *Intern. Z. Wasser Versorgung.* 2, 84-7(1915).—The city of Luckenwald decided to secure a new water supply. In order to obtain the softest water possible a hydrological survey was made. This consisted of analyzing water from springs and wells and also from the various water courses. Borings were made and curves of equal hardness were drawn. These showed that the hardness varied in the territory investigated. By means of this systematic investigation a continuous supply of softer water than might have otherwise been obtained, was secured.

FRED W. TANNER.

Biochemical and engineering aspects of sanitary water supply. G. W. FULLER. *J. Frank. Inst.* 180, 17-61(1915).—An address.

W. F. L.

Purification of boiler feed water. E. BROWN. *Met. Chem. Eng.* 13, 156-60(1915).—A review.

W. F. L.

Value of chemical examination of ground waters. R. HAACK. *Z. Ver. Gas- u. Wasserfachm. Oesterr. Ungarn.* 55, 200-2(1915).—The bacterial exam. of ground waters is not necessary at intervals as frequent as in the case of chem. exam. Some of the advantages of a chem. analysis mentioned are as follows: physical appearance, whether or not a ppt. will form on standing, CO_2 content, nature of Fe and Mn compds. if present, hardness, whether Cl is united to Na or Ca, forms of N organic matter as shown by O consumed.

F. W. TANNER.

The necessity of an iron removal plant. F. H. SCHILLING. *Intern. Z. Wasser Versorgung.* 2, 69-71(1915).—The objectionable features of an iron-bearing water are considered from an industrial and sanitary standpoint.

F. W. TANNER.

The necessity of an acid removal plant. F. H. SCHILLING. *Intern. Z. Wasser Versorgung*. 2, 77-9(1915).—Acid-ground waters often attack the pipes and walls of concrete reservoirs and pipes are sometimes clogged by pptn. of the substances thus dissolved. The most objectionable factor to be considered is the solution of Cu and Pb. Lead poisoning from water has reached epidemic proportions in a few German cities. In cities using acid-ground water, tin-lined pipes are sometimes used. F. W. T.

Sterilization of drinking water by compressed calcium hypochlorite tablets. M. VINCENT AND M. GAILLARD. *Compt. rend.* 160, 483-6(1915); *J. pharm. chim.* 11, 271-5(1915).—Three sizes of tablets are prepared, for 1, 5 and 10 l. of H_2O , containing, resp., 0.015, 0.075 and 0.15 g. of $CaOCl_2$, and 0.08, 0.38 and 0.60 g. of NaCl as an adjuvant. They yield 3-3.5, 17 and 35 mg. of Cl. NaCl efficiently aids in the diffusion of Cl through the H_2O which is almost complete after 20 min. Results of about 30 analyses of natural and polluted waters show a decrease of N (albuminoid and NH_4) by 25-75%. Odors due to putrid fermentation disappear completely. Pathogenic bacteria are killed after 10 or 12 min.; in presence of 1:2 pts. per mil. organic N, in 10 or 15 min., non-pathogenic bacteria are markedly reduced in numbers. The tablets when kept dry, cool, and in the dark, will retain their strength for several months. S. WALDBOTT.

Some filtration plant bacteriological data. R. D. SCOTT. *Ohio Pub. Health J.* 5, 734-41(1915).—The bacterial character of water during periods of long storage varies from that of flood stage in that (1) count is less, (2) ratio between 37° and 20° counts is higher and (3) *B. coli* of saccharose-fermenting type are more numerous. In CaO-softened water bacterial count is less, ratio of *B. coli* to total bacterial count is less and ratio between 37° and 20° counts is higher. The proportion of dextrose but non-lactose fermenters is greater, and saccharose-fermenting *B. coli* are more numerous. The proportion of non-fermenting dulcitol organisms is not affected by storage or CaO. This is true of non-indole-formers. The coli group is about 4% of the 37° count, the ratio being irregular. J. GAUB.

Examination of drinking water on railroad trains. R. H. CREEL. *U. S. Hyg. Lab. Bull.* 100(1914).—C. made a bacteriol. survey of drinking water served on trains entering Washington, D. C., from all parts of the eastern U. S. The methods of examn. employed were not standard, being essentially as follows: Fermentation tests were made in both lactose broth and bile, using 5 and 10 cc. quantities of water. Transfers from positive gas tubes to Endo plates and also to plain agar tubes at 75° , were made. Typical colonies on Endo plates were considered positive indication of *B. coli*. Doubtful colonies were inoculated into lactose broth from which final results were recorded. If, with a *B. coli* negative Endo plate, an anaerobic growth with gas production was obtained in the agar tube at 75° , the original fermentation was attributed to an anaerobic spore-forming bacillus. Counts were made on agar at 37° . Of the 1000 samples examd., 421 showed gas in the presumptive test when 10 cc. quantities were inoculated. Only 91 samples were confirmed as contg. *B. coli* while the remaining 330 were recorded as contg. gas-producing anaerobes. Two types of anaerobes were found; the characterization of these is given. Samples collected from mail cars and day coaches were found to indicate *B. coli* much more frequently than were samples from sleeping and dining cars. W. F. LANGLELLER.

Algae troubles in Italian waterworks. G. GASPERINI. *Intern. Z. Wasser Versorgung*. 2, 83-4, 91-2(1915).—G. cites several instances where peculiar odors and tastes in water supplies have been due to algae. Beggiatoaceae give the greatest amt. of trouble. To prevent algae troubles, distribution systems should be kept flushed. Sometimes it is necessary to resort to such disinfectants as Cl and $Ca(OCl)_2$.

FRED W. TANNER.

Sanitary features of the Los Angeles aqueduct. E. O. SLATER. *J. Ind. Eng. Chem.* 7, 622-5(1915).—An address. ISADOR MILLER.

The water supply of the city of Halle a/S. H. PRECHT. *Chem. Ztg.* 39, 410-2 (1915).—Monthly analyses of H_2O from the Elster and Saale rivers and that supplied to Halle are given from Dec. 1912 to Mar. 1915, showing that the proximity of these polluted streams to the region from which the city supply is drawn has not affected the latter. J. H. MOORE.

Water purification at Columbus, Ohio. C. P. HOOVER. *Ohio Pub. Health J.* 5, 709-34(1915); cf. *C. A.* 8, 2766; 9, 495.—H. describes water filtration, methods of analysis for chemicals used, and specifications for the purchase of chemicals. J. GAUB.

River pollution in colliery districts. *Colliery Guardian* 109, 752-3, 820-1(1915).—*Final report of the Royal Commission on Sewage Disposal.* Coal washing water can be effectively dealt with by settlement in tanks or ponds; not more than 4 pts. per 100,000 should remain in the effluent. Na_2SO_4 liquor and spent gas liquor from shale oil distn. plants are allowed to settle in tanks and then pumped onto heaps of spent shale which further filter it. Spent gas liquor from coke ovens may be evapd. either by using it for coke quenching or by means of waste heat in specially constructed evaporators. Under no circumstances should it be discharged untreated into a stream. H. L. OLIN.

Purification of farm drainage. H. WEIGMANN AND A. WOLFF. *Milchwirtsch. Zentr.* 44, 65-73(1915).—Expts. are described in which treatment of drainage water by various methods is given, e. g., by fullers' earth, milk of lime, and $FeSO_4$; the last is recommended. L. L. VAN SLYKE.

Liquid trade wastes. ANON. *Engineering* 99, 483-4(1915).—The Ninth Report of the Royal Commission on Sewage Disposal recommends that the effluent from a works shall not contain more than 40-60 p. p. m. of suspended matter, and shall not absorb more than 20-60 p. p. m. of dissolved O in 5 days. W. W. HANFORD.

Concentration of sewage sludge. J. GROSSMAN. *J. Soc. Chem. Ind.* 84, 588-92 (1915).—A sludge should contain at least 20% solid matter if it is to be subsequently dried by heat. Ordinary settling tank sludges containing only 10% solid matter can economically be 50% dehydrated by treatment with 3 parts per 1000 of H_2SO_4 . It is claimed that this method is more economical than other methods of preliminary water elimination that have heretofore been proposed. W. F. LANCELIER.

Dickson centrifuge system of sewage treatment. E. H. TRIPP. *J. Soc. Chem. Ind.* 34, 517-24(1915).—Sewage sludge taken from settling tanks is treated with 0.5% brewers yeast, warmed to $94^\circ F.$, and allowed to stand in shallow troughs for 24 hrs. In this manner a sepn. of solid and liquid is obtained. The action is due to anaerobic bacteria which feed on the yeast and form gas. The treatment eliminates $1/2$ of the water normally present in the raw sludge. The sepd. sludge is dried in a mechanical heating device and is sold as fertilizer. A centrifuge filter for use in sewage treatment is also described. W. F. LANCELIER.

Treatment of sewage sludge. R. O. WYNN-ROBERTS. *Can. Eng.* 28, 697-9 (1915).—Discussion of paper presented by Gillespie (*C. A.* 9, 830). The processes discussed cover grit chamber treatment, screening, sedimentation, degreasing, biologic treatment (including recent expts. on aeration of sewage with activated sludge) and sludge disposal. ARTHUR LEDERER.

Report of sewage disposal, Columbus, Ohio. C. B. HOOVER. *Ann. Rept. for* 1914, 32 pp. H. P. CORSON.

Reinsch-Wurl sewage screens, Brooklyn. ANON. *Eng. News* 73, 1224-5 (1915).—Two 6-million gal. sewage screens are to be installed at the sewage treatment plant of the 26th Ward, Brooklyn, N. Y. The specifications and plans were prepared on a competitive basis permitting the use of Imhoff tanks or sedimentation tanks with separate sludge-digestion and sludge-drying beds for either of the tank plants, and Riensch-Wurl fine screens. A partial list of foreign screen installations is given; also views showing screening operations at Dresden, Germany. ARTHUR LEDERER.

The practical use of disinfectants. H. E. HASSELTINE. *U. S. Pub. Health Reports* 30, 2049-60 (1915).—Disinfectants properly applied are a good preventative for communicable diseases. The choice must be made with consideration of conditions. HCHO is the simplest and most efficient for gaseous disinfection. Control tests should be made to check the efficiency of the substance used. J. GAUB.

Destruction of flies and the disinfection of cadavers in war zones. E. ROUBARD. *Compt. rend.* 160, 692-3 (1915).—Heavy coal tar oils spread upon fecal matters prevent the attraction of flies. In treatment of manures intended for fertilizer, a 5% soln. of sodium cresolate should be substituted. $\text{Fe}_2(\text{SO}_4)_3$ either pulverized or as a 10-20% soln. is suitable for disinfecting cadavers. Hypochlorites, FeSO_4 and CaO were tried and found inferior. W. F. LANGELIER.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Soil colloids and their adsorption power. P. ROHLAND. Stuttgart. *Landw. Jahrb.* 47, 239-47 (1914).—A considerable part of this paper is a criticism of views by Ehrenberg, Oryng, Gorski and others on the adsorption of complexly constituted color compounds, such as crystal violet, by soil colloids. R.'s expts. show that kaolin has different adsorption properties depending upon its origin and method of formation. The presence of numerous colloids in clay, clayey soils, peat and red-earth explains the greater adsorptive powers of these soils, also their properties of contraction on evapn. and their solvent action towards such crystalloids as phosphoric acid, potash and lime. This

results from the greater water imbibing power of these soils due to the colloids present. The adsorption of complexly constituted color compounds by these soils makes possible a quant. colorimetric detn. of the colloids. The colloids have the property of taking up in large quantities foreign solids such as sand, when in the form of powder, without altering the original properties of the soil.

J. R. SCHROEDER.

Notes on the colorimetric determination of phosphorus in soil extracts. C. E. MILLAR AND F. A. GANGLER. *J. Ind. Eng. Chem.* 7, 619(1915).—The method of Veitch (*J. Am. Chem. Soc.* 25, 169(1903)) is considered sufficiently accurate. I. M.

Variation of the fertility of soils under the influence of natural conditions and dry air storage. K. GHEDROIZ. *Selkoe Khosiastro i Lessovodstro* 47, 630(1914); *J. Soc. Chem. Ind.* 34, 502.—Soil when stored in dry air gave increased productivity in proportion to the length of storage; the H_3PO_4 and N contents of the plants grown thereon, and the citrate-sol. P_2O_5 of the soil, vary in like manner.

R. O. E. D.

Effect of moisture content of a sandy soil on its nitrogen-fixing power. C. B. LIPMAN AND L. T. SHARP. *Botan. Gaz.* 59, 402-6(1915).—A light sandy soil from a walnut grove in Anaheim, Calif., was employed, and the natural N-fixing flora thereof studied in its relations to moisture. The soil-culture method was used in which 50-g. portions of soil were mixed in tumblers with 1 g. of mannitol and water added in varying quantities. The mixt. was stirred with a sterile spatula, the tumblers covered with Petri dish covers and incubated at $28-30^\circ$ for 21 days. The N fixation in a sandy to sandy-loam soil by means of its natural flora, and under optimum temp. conditions, takes place most actively with a water content ranging from 20 to 24%, based on the air-dry weight of soil, or 22.5 to 26.5% based on the water-free soil.

The determination of the sulfoxyg power of soils. P. E. BROWN AND E. H. KELLOGG. Iowa State College. *J. Biol. Chem.* 21, 73-89(1915); see *C. A.* 9, 833.

A. P. L.

New experiments on alkali soil treatment. Preliminary report. CHARLES B. LIPMAN AND LESLIE T. SHARP. Univ. Calif. *Agric. Sci.* 1, 275-90(1915).—Pot tests with barley were carried out on an alkali soil. The soil was distributed in 8-inch earthenware pots in portions of 6 kg. each and the pots were then treated as follows: untreated, 30.42 g. actual H_2SO_4 , 41.76 g. actual H_2SO_4 , 11.02 g. actual H_2SO_4 , 62.08 g. $CaSO_4 \cdot 2H_2O$, 6 g. $CuSO_4$ calcd. as anhydrous salt, 30 g. $FeSO_4$ calcd. as anhydrous salt, 12 g. Na_2SO_4 (anhydrous) and 300 g. air-dry barnyard manure. The beneficial effect of the smallest amount of H_2SO_4 applied is especially noteworthy. Gypsum, $FeSO_4$, and barnyard manure treatments were instrumental in improving the producing power of the soil for barley. $CuSO_4$ and Na_2SO_4 were without effect in a positive direction and appeared even to render the soil a much poorer medium for the growth of barley than it was before treatment. Root yields do not appear to follow in a general way the yield of tops.

W. H. FRY.

Note on the formation of tricalcium phosphate on mixing ground limestone with acid phosphate. R. N. BRACKETT AND B. FREEMAN. Clemson College. *J. Ind. Eng. Chem.* 7, 620(1915).—On mixing ground limestone with acid phosphate, $Ca_3(PO_4)_2$ is formed immediately and the amt. of this increases slightly on standing. I. M.

Utilization of Pacific kelp. J. W. TURRENTINE. U. S. Bur. of Soils. *Pacific Fisherman* 13, No. 6, 13-4, 36, 38, 40(1915); cf. *C. A.* 9, 1218.—A discussion of the feasibility of combining the treatment of kelp with the rendering of cannery waste. The botany of kelp, its distribution, quantity, chem. compn., and fertilizer qualities are described.

W. H. FRY.

Composition of certain fish fertilizers from the Pacific coast and the fertilizer value of degreased fish scrap. J. R. LINDEMUTH. Bur. Soils. *J. Ind. Eng. Chem.*

7, 615-9(1915).—Analytical. The average comp. of the waste is N 9.31%, P_2O_5 6.72%, oil 12.69%. This material is high in fertilizer value. ISADOR MILLER.

Waste products of agricultural interest: wool and leather wastes. E. J. RUSSELL. *J. Board Agr.* 21, 1087; *J. Soc. Chem. Ind.* 34, 439.—Middle grade shoddies have long been used for hops and fruit. At Rothamsted it has been shown that they are also good for ordinary farm crops, and on heavy soils. Shoddy is one of the cheapest nitrogenous fertilizers on the market. Processed shoddy, which has been treated with H_2SO_4 or has had the oil removed, is no better than untreated material. Untreated leather waste is of no value but treated has given some promising results. Untanned leather and scrap from glove-making possess fertilizing value. R. O. E. D.

Antagonism between anions as affecting barley yields on a clay adobe soil. C. B. LIPMAN AND W. F. GERICKER. *J. Agric. Res.* 4, 201(1915).—Expts. to det. the antagonism between the anions of the ordinary alkali soil were carried out under greenhouse conditions. The results indicated the existence of antagonism between anions in a clay-adobe soil for barley as follows: between NaCl and Na_2SO_4 and between NaCl and Na_2CO_3 in the second crop (none shown in the first crop); slight antagonism between Na_2CO_3 and Na_2SO_4 in the first crop. Marked antagonism exists in both first and second crop between Na_2SO_4 and $CaSO_4$ in soil cultures. It was found that 0.1% each of NaCl and Na_2SO_4 stimulates barley in the first crop and is toxic in the second. Na_2CO_3 does not show toxicity but stimulates up to 0.3% of the dry wt. of soil.

R. O. E. D.

The Woburn pot culture experiments. J. A. VOELCKER. *J. Roy. Agr. Soc.* 75, 306-322(1914); cf. *C. A. S.* 8, 2772.—I. Hills' Experiments: (a) *The influence of copper sulfate on wheat.* $CuSO_4$ in soil in pots was injurious to wheat when used in amts. of 0.05% of Cu. Quantities less than this had a slightly stimulating effect. $CuHPO_4$ in amts. as high as 0.10% Cu had no harmful effects. $CuCO_3$ in amts. of 0.10% Cu was as harmful as $CuSO_4$, but was stimulating in amts. of 0.02% Cu. $Cu(NO_3)_2$ in as small amts. as 0.02% Cu was harmful, and was stimulating in smaller amts. $Cu_3(AsO_4)_2$ was harmful in as small amts. as 0.005% Cu. (b) *The influence of lead salts on wheat.* $Pb_3(PO_4)_2$, $PbCO_3$, $Pb(NO_3)_2$, $PbSO_4$ and $PbCl_2$ in amts. of 0.03 to 0.10% Pb were slightly stimulating. There was no indication of toxicity in any of the cultures. II. *The relation of lime to magnesia in soils.* $CaCO_3$ in quantities of 2.5 to 4.5% added to a soil rich in Mg gave increased yields of barley. It is shown that Ca can be added without detriment in amts. double the quantity of Mg in the soil. III. *Acidity of soil.* Barley was grown, in pots, in soil from the Rothamstead $(NH_4)_2SO_4$ -treated plots to test the effect of different amts. of Ca. Acid soil from plots which failed to produce crops was benefited by adding $CaCO_3$ in amts. to exceed that required to neutralize. Acid plots which still produced crops, were not benefited by $CaCO_3$ exceeding the amt. required to neutralize, and the plots which gave a neutral reaction were not benefited by $CaCO_3$ in any amts.

J. J. SKINNER.

Pot tests with fertilizer compared with field trials. G. N. COFFEY AND H. F. TUTTLE. *J. Am. Soc. Agron.* 7, 129-39(1915).—Fertilizer requirements of soils as detd. by growing wheat 4 to 6 weeks in pots containing 40 lbs. of soil are correlated with the requirements as determined by long continued field plot tests. Three soil types were used in these tests. To secure best results it was found that the soil should be placed in pots in the same relative position and condition as in the field, using both soil and sub-soil. Air drying and excessive handling should be avoided. J. J. S.

Constituents of the fruit of the Osage orange (MCHARGUE) 12. Potash salts, 1914 (PHALEN) 18. Potash from kelp (CAMERON) 18. Sludge from the sulfide process of depilating skins (HELFRICH) 29. Atlantic coast menhaden industry (GREER) 27.

U. S., 1,144,405, June 29. T. L. WILLSON and M. M. HAFF. A fertilizer is made by fusing feldspar (*e. g.*, orthoclase) with Ca phosphate and either using the product directly as fertilizer or leaching it and evapg. the soln. to dryness. Carnallite or kainite may be added to the mixt. and fluxes such as fluorides, borates or Fe oxide may also be included in the charge. Cf. C. A. 9, 839.

U. S., 1,144,905, June 29. L. KERN. Fertilizer is made by atomizing or fermenting waste sulfite liquor to remove the SO_2 or carbohydrates and then mixing it with kieselguhr and $\text{Ca}(\text{NO}_3)_2$ or other fertilizer ingredients. Cf. C. A. 9, 950.

Brit., 5,184, Feb. 28, 1914. T. TWYNAM. In mfg. fertilizers finely ground basic phosphatic slag is treated with a restricted amt. of HNO_3 , insufficient to act upon the Fe compds. or to cause the formation of gelatinous SiO_2 to any notable extent. The HNO_3 is preferably obtained from the air by an elec.-arc process. After drying, the deliquescent mass which is obtained may be converted into a dry condition by adding K, NH_4 , or Na sulfates. The $\text{Ca}(\text{NO}_3)_2$ may be sepd. from the mass by soln.

Ger., 281,766, Dec. 10, 1913. C. BÖHRSCH. Process of mfg. a non-dusting bone meal without affecting its value as a fertilizer or increasing its cost materially, consisting in mixing finely ground bone meal with definite amts. of H_2O and adding small amts. of acids or acid salts. At a certain stage of the process a portion of the added H_2O is removed, by artificial drying by heat, either immediately after the mixing or before packing. By the addition of H_2O the small amts. of glutinous substance present in the meal are removed by soln., and form with the small amts. of phosphate, which are likewise dissolved by the acidified H_2O , a glutinous mass which binds the dust particles together. After expulsion of the excess H_2O , a non-dusting, granular product is obtained which may be strewn readily. The addition of acid or acid salts prevents molding in stored masses, and also converts a portion of the $\text{Ca}_3(\text{PO}_4)_2$ into CaHPO_4 , which, in consequence of its greater solubility, increases the value of the product as a fertilizer. *E. g.*, 100 kg. finely ground bone meal of about 30–33% H_4PO_4 content are mixed with about 40 liters H_2O and 10 kg. waste H_2SO_4 from mineral oil refinement (about 50° Bé.) until the product is of uniform texture, which is accomplished in several mins. The excess H_2O is then removed in drying app.

Ger., 282,259, Nov. 13, 1913. J. PLEINES. In a process of mfg. a copper-lime powder for plant treatment, paraffin, ceresin, wax, or the like, is added to the CaO when it is slaked, and the resulting powder is mixed with dextrin or the like. The heat of slaking melts the paraffin, ceresin, or the like, which is absorbed by the $\text{Ca}(\text{OH})_2$. After slaking, the $\text{Ca}(\text{OH})_2$ satd. with paraffin or the like, is dried and pulverized. On account of the absorbed material the mass is preferably ground with the addition of charcoal or the like. In addition to dextrin or a similar binder, S or any other suitable substance is added, when required, to the $\text{Cu-Ca}(\text{OH})_2$ powder. The addition of paraffin imparts to the powder the property of softening in the heat of the sun and of spreading over the surfaces treated, and causes it to adhere firmly. If the powder contains S the oxidation thereof causes an increase in the temp. and favors the melting of the paraffin in the air. The addition of dextrin or the like insures adhesion of the powder under conditions of dew and wet weather. The product is claimed to serve especially in protecting plants against *Peronospora*, *Oidium*, or the like. In order that it may be applied also to protect against animal parasites, nicotine, Schweinfurth green, and other poisons, may be added when the CaO is slaked.

Ger., 282,461, Aug. 18, 1910. W. MATHEIUS and H. BLOME. From phosphorites, by fusion, compounds of citrate soluble phosphoric acid can be obtained if the chem. conditions are so controlled that the formation of a compd. of the formula $5\text{CaOP}_2\text{O}_5\text{SiO}_3$ may be formed.

Ger., 282,532, Mar. 19, 1914. L. WILKENING. Mfg. a permanent non-hygroscopic fertilizer which is easily strewn, by mixing peat with molasses distillers' slops, and subjecting the mixt. to bacterial fermentation to destroy the hygroscopic constituents. The fermentation of the slops is interrupted by the addition of dil. acids, in order to prevent a further decomp. The required bacterial solns. can be obtained by treating decomposed animal fertilizers with dil. slops. E. g., peat meal is satd. with molasses slops of about 10° Bé., inoculated with a pure culture or with a bacterial soln. produced from decomposed horse manure with dil. slops, or with a mass already in fermentation, and then the mixt. is enriched with slops of about 20° Bé. until the desired N content has been reached. The fermentation is discontinued by drying alone, or with the addition of dil. acids. A mixed fertilizer is obtained which contains N, K, P, Ca, in proper proportions.

Ital., 131,528, Apr. 15, 1913. G. CRIFFA. A fertilizer consists of a mixt. of Ca phosphate and chloride in varying proportions, dependent upon the nature of the soil to which it is to be applied.

ROBERT WAHL.

Increasing production of South American wines. LEO J. KEENA. Consul General, Valparaiso. *Commerce Reports* 161, 182-5(1915).—Statistics for 1913-4. E. H.

The formation and determination of the acids in malt and barley and their extracts. H. LÜERS AND L. ADLER. *Z. Nahr.-Genussm.* 29, 281-316(1915).—(1) *The formation of the acids: an enzymic process.* In the extn. of malt in barley meal with H₂O, acid-forming enzymes become active. The acid formed is for the most part phosphoric, produced by the action of phytase upon phytin. Expts., were conducted showing the influences of conc., temp., time, and conc. of H ion. An extn. period of 3 hrs. at the optimum temp. of 53° gives the greatest yield of acid. The proportion of malt to H₂O can be altered without affecting the result. The influence of the conc. of H ion cannot be definitely detd. on account of other influences, but it was found that a H ion conc. of more than 10⁻⁶ and smaller than 4 × 10⁻⁷ hinders the enzymic action. By treating with boiling alc. the action is completely stopped. (2) *Methods of detg. the acids in malt and barley.* There are 2 kinds of acids to be dealt with, those originally present and those formed by enzymic action during extn. *Detn. of acids originally present in malt.* Forty g. of the finely ground malt or barley are treated in a beaker with 40 cc. of 96% alc. which has been neutralized with NaOH; with barley 50 cc. is used. Should this amt. not be sufficient thoroughly to permeate the mass a little more is added. The beaker is heated on a water bath at 78-80° for 20 min. in the case of malt, and 30 min. with barley, stirring repeatedly to allow the most of alc. to escape. The mixt. should now have a plastic, doughy consistency; if not, the heating should be continued a few min. After cooling, 150 cc. of distd. H₂O and 10 drops toluene are added, the mixt. stirred and allowed to stand with occasional stirring for 3 hrs. or longer. The wt. is brought up to 240 g. with H₂O, the mixt. repeatedly filtered through a folded filter until the filtrate is only weakly opalescent. Fifty cc. portions are pipetted off for analysis and for a blank and titrated with 0.1 N NaOH, using phenolph. and the acidimeter of H. Lüers (cf. C. A. 8, 3613). *Detn. of total acids in extracts of malt and barley.* Forty g. finely ground malt or barley are mashed with 150 cc. distd. H₂O at 50°, treated with 0.5 cc. toluene and extd. at 53° for 3 hrs., stirring at definite intervals. It is then cooled to room temp., brought up to 240 g., and 50 cc. portions titrated as before. *Calculations.* The results are expressed as cc. N acid per 100 g.

dry substance. $Sr = 10 m. \{[R + W(C/100)]\} / \{F[C - W(C/100)]\}$; $Sr = \text{cc. } N \text{ acid per } 100 \text{ g. dry substance}$; $m = \text{cc. } 0.1 \text{ } N \text{ alkali required}$; $R = \text{added } H_2O \text{ in g.}$; $W = \% H_2O \text{ in the substance}$; $C = \text{g. substance weighed out}$; $F = \text{cc. filtrate used in titration}$. For the proportions used in the above procedure the equation is simplified to, $Sr = m \cdot (100 + 0.2 W) / (100 - W)$. The acid formed by enzymic action is found by difference. Taking the second formula above as a basis a table was worked out which permits the cc. N acid, which corresponds to a known H_2O content and cc. $0.1 \text{ } N$ alkali used, to be read off directly. As an av. example of several detns. which are given in a table, a certain malt showed an original acidity of 6.67 cc. N acid per 100 g. dry substance, total acidity 15.69 cc., and acids formed by enzymes 9.02 cc. L. D. ELLIOTT.

Enzymes in beer. ARMINIUS BAU. *Wochschr. Brau.* 32, 189-91(1915).—The mature bottom fermented beer used in the expts. was freed from suspended yeast-cells by filtration through filter paper (Schleicher and Schüll "Nr. 602 hard"). Biological control tests with samples thus treated proved conclusively the absence of wild yeasts and bacteria in each case. Positive results were obtained in the tests for invertase, melibiase, and amygdalase. Maltase, trehalase (most probably), emulsin, carboxylase, lipase, endotryptase, catalase, oxidase, reductase and yeast rennet do not occur in beer. L. W. HAAS.

Top-fermenting yeasts and their sugar transforming capacity. F. SCHÖNFELD. *Wochschr. Brau.* 32, 167-9(1915); cf. *C. A.* 9, 506.—In fermentation expts. with top- and bottom-fermenting yeasts, the latter attained in all cases higher attenuations. For all expts. a light, hopped, fresh wort served as fermentation liquid; it was dild. and beet sugar added in various proportions before pitching with the different yeasts. L. W. HAAS.

A new variety of hops, the "foundling." E. S. SALMON. *Brewers' J. (London)* 51, 343-5(1915).—The new hop appears to be distinct from all cultivated hops. Its characteristics are: good cropping qualities, high resin content (9.84 to 12.44%, av. 11.26%), marked resistance, if not total immunity from, the "nettle-head" disease, and lateness of season (coming after the "fuggles"). L. W. HAAS.

Melanoidins and the nomenclature of the coloring substances of malt. C. J. LINTNER. *Wochschr. Brau.* 32, 201(1915).—L. opposes Zikes' proposal (*C. A.* 9, 1221) to term Maillard's melanoidins (the coloring principles of malt) "orphneins" or "aterins." L. W. HAAS.

Computation of yield of extract. W. WINDISCH. *Wochschr. Brau.* 32, 149-51, 157-9, 165-7, 173-5, 181-5(1915).—A historic-critical representation of the calcul. of the ext.-yield of malt in breweries. L. W. HAAS.

Use of compressed air for tapping beer. F. SCHÖNFELD. *Wochschr. Brau.* 32, 185-6, 191-3(1915).—Beer tapped by means of compressed air held a satisfactory foam and preserved a fresh taste the first day. The detrimental effect on foam holding capacity and taste gradually increased until after 4 days the latter could be called "flat." The CO_2 content of beer in contact with compressed air gradually decreases. Employing compressed air under a pressure of 0.75 atm., beer retains (during the first day 95-98% of its CO_2 , provided the vol. of air in the cask is relatively small. The decrease in CO_2 was 6-10% if the cask was emptied to 0.5 its vol. during 2 days, and reached 30% if the cask was completely emptied after 3 days. The use of compressed air in place of CO_2 , therefore, can only be recommended where the beer is quickly consumed after tapping. L. W. HAAS.

Alcohol industry in Italy. S. CETTOLINI. *Boll. ist. int. agric.* 6, 16; *Ind. chim. min. met.* 2, 80-2(1915). CHAS. A. ROULLER.

Alcohol from cassava. A. E. COLLENS. Dept. Agr., Trinidad and Tobago *Bull.*

14, 56(1914); *J. Soc. Chem. Ind.* 34, 629.—Sweet cassava roots, when pulped, boiled, saccharified with malt, fermented, and distd., yielded a quantity of alc. corresponding to 75.6 gals. of 94% alc. per ton of dry material. In another expt., where the starch was saccharified with taka-diastase, the yield amounted to 81.5 gals. of 94% alc. per ton of air-dried slices.
E. J. C.

Dried yeast as stock food (CROWTHER) 12. New alcohol fuel 21.

Brit., 5,025, Feb. 26, 1914. E. CANTOR. Removing the bitter taste and burnt smell and taste from malt extracts and worts, particularly those prepd. from caramelized malt, by passing steam through the liquids.

Ital., 133,023, July 19, 1913. S. BOSIA. App. for the rapid determination of alcoholic content of wines, based upon the principle of cohesion of liquids, by means of which the % alc. is indicated directly on a graduated scale which measures the cohesive power of the wine by capillarity.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Guyot tar. N. PETKOW. *Z. öffent. Chem.* 20, 232-3(1914).—Analyses of Guyot tar, which contains 0.1% codeine, and of Goudron water made from wood tar and from Guyot tar, are given.
H. S. BAILEY.

Determination of oxychlorides and free acid in liquor ferri sesquichlorati. G. ROMIJN. *Ber. pharm. Ges.* 25, 142-5(1915); cf. *C. A.* 9, 1971.—The reagents required are: *N* thiosulfate soln. and CuCl_2 -starch (mix 1 g. CuCl_2 with 49 g. starch dried at 100°). Pour 2 cc. of the sample (liquor ferri sesquichlorati, Ger. Pharm.) into an Erlenmeyer and add cold CuCl_2 -starch soln. (0.5 g. dissolved in hot H_2O) and 5 cc. *N* $\text{Na}_2\text{S}_2\text{O}_4$. After decolorization, add methyl orange-methylene blue soln., which in the case of acid reaction develops a purple, in case of an alk. reaction a green color. If the reaction is acid, titrate with 0.1 *N* NaOH drop by drop but as quickly as possible, the color change being best recognized by observing the liquid vertically over a white surface.
W. O. E.

Legal protection of medicaments during the war, with particular reference to patent and trade mark law. J. MAGNUS. *Ber. pharm. Ges.* 25, 3-31(1915).
W. O. E.

Hydrargyrum oxycyanatum. J. HERZOG. *Apoth. Zig.* 30, 79-80(1915).—The suggestion is made that the above title be modified to include two preps., one: hydrargyrum oxycyanatum verum containing 98.2%, the other: hydrargyrum oxycyanatum with 33.2% $\text{Hg}(\text{CN})_2 \cdot \text{HgO}$.
W. O. E.

Manufacture of antipyrine. ANON. *Chem. and Druggist* 85, 37(1914).—A description is given of the com. process including the manuf. of PhNHNH_2 from C_6H_6 , the production of $\text{AcCH}_2\text{CO}_2\text{Et}$, the condensation of these and the methylation of the condensation product.
J. GAUB.

What is rice powder? CHARLES H. LAWALL. *Am. J. Pharm.* 87, 293-9(1915).—A statement of results of examn., together with information concerning the place of purchase, price and manner of labelling toilet powder commonly known as "Rice powder." Of the 16 samples examd. but 2 were genuine and only 6 contained rice starch at all. In 8 of the samples, corn starch was used in place of the more expensive rice starch, and in 2 samples no starch of any kind was present, the constituents being wholly of a mineral origin. Talc was present in 13 out of the 16 samples. The constit-

uents used in place of rice powder (chalk, talc, ZnO , $\text{Bi}(\text{NO}_3)_3$ and corn starch) are not harmful; some are cheaper and some are more expensive than rice powder would be.

W. G. GAESSLER.

The utilization of our own resources in producing dyestuffs and drugs. JOSEPH JACOBS. *Am. J. Pharm.* 87, 300-8(1915).—A discussion. W. G. GAESSLER.

Pituitary standardization. A comparison of the physiological activity of some commercial pituitary preparations. G. B. ROTH. U. S. Hyg. Lab. *Bull.* 100.—A comparison of the physiol. activity of some com. pituitary exts. by the blood pressure, intact uterus, and isolated uterus methods showed them to possess a wide range of physiol. activity, the ratio of variability between the strongest and weakest by the blood pressure method being 15 to 1, by the intact uterus method about 10 to 1, and by the isolated uterus method about 7 to 1. The isolated uterus method, using the young virgin guinea pig as a test animal and a standard of a 1 to 20,000,000 diln. of β -iminoazolyethylamine hydrochloride, is considered the most satisfactory. An arbitrary standard of activity for com. pituitary exts. making a 1 to 10,000 diln. of the ext. equal in activity to a 1 to 20,000,000 diln. of the standard when the isolated uterus of the virgin guinea pig is used, is suggested. A wide variability in the physiol. activity of com. pituitary exts. has been found, but no positive reason could be assigned for such differences in activity.

W. W. HANFORD.

The constituents of Kuromoji oil. RUKORO SHINOHARA. *J. Chem. Ind. Japan* 18, 417-34(1915).—The following classes of substances are present: esters, 11.41%; free alc., 20.21%; cineol, 7.71%; terpenes, 50.95%; phenol and free acids, trace; aldehydes and ketones, 9.70%. The alcohols are chiefly linalool, 11.43% and geraniol 7.16%. Cineol was detd. by the HBr method, linalool by fractional distn., and geraniol by the CaCl_2 and phthalic acid methods.

H. L. OLIN.

New method of preparing tincture of iodine. ETTORRE RICCOBONO. *Boll. chim. farm.* 53, 297-9(1914).—The procedure proposed by Courtot for preventing the formation of HI in tincture of I, i. e., by addition of 4% KI to a 10% tincture, is regarded as not being perfectly satisfactory because of the presence of an alk. salt. The same objection applies to the "iodoine" tablets now on the market. These tablets are of 2 kinds: 1 kind contains tartaric acid while the other is composed of a mixt. of NaI and NaNO_3 . One tablet of each kind dissolved in 10 cc. H_2O produces 0.5 g. free I, the latter passing at once into soln. because of the excess of NaI. This soln. has the further disadvantage of containing an alk. tartrate; the substitution of H_2O for alc. as a vehicle is also a disadvantage, inasmuch as the latter evaps. more readily from the skin, assists the absorption of the I and has an antiseptic action of its own. The most desirable procedure for preventing the formation of HI in tincture of I, or of destroying it if already formed, is furnished by the method mentioned by Roques, i. e., by the reaction of HI and HIO_3 to form I and H_2O . HIO_3 is prepd. as a powder by pptg. a cold satd., aq. HIO_3 soln. with alc.; 10 g. of this powder are then added to each l. of the tincture and the latter is shaken for 5 min. This proportion of HIO_3 is sufficient for the oxidation of the max. amt. of HI (1 pt. HI to 5 pts. I, according to Roques) which may be present in a tincture of I prepd., say 8-9 mos. previously. The presence of an excess of HIO_3 on the bottom of the containing vessel may be taken as an indication that all HI has been transformed. Any appreciable increase in the I content of the tincture due to the reaction of HI and HIO_3 may be readily corrected by titrating a portion of the tincture with 0.1 N hyposulfite soln. and adding the required amt. of 95% alc.

H. S. PAINE.

Extemporaneous preparation of solutions of sulfur dioxide. CHENEY. *Boll. chim. farm.* 54, 359(1915).—In a bottle of 250 cc. capacity provided with a ground-glass stopper are placed 5.7 g. dry Na_2SO_3 and 18 cc. dil. HCl; the bottle is then quickly

stoppered and set in a cool place. The contents are shaken cautiously so as to facilitate soln. of the salt; when effervescence has ceased 25 cc. H_2O are added and the mixt. is shaken for several mins. The vol. of the final soln. is 40 cc. and the SO_2 content is 6-6.4%.

H. S. PAINE.

Use of the Bettendorf reagent in tests of purity of medicinal antimony preparations.
ALFREDO PAGNIELLO. Turin. *Boll. chim. farm.* 53, 689-91 (1914).—This preliminary work was confined to tests of the Sb preps. (Kermes mineral, Sb_2S_3 , Sb and K tartrate, Sb_2S_3) occurring in the official pharmacopeia (Italian), 5 or 10 cc. of the Bettendorf reagent being employed for each test. Kermes mineral gave no ppt. and no coloration in 4 hrs. Sb_2S_3 in 10 min. gave a slight coloration which gradually became more intense; in 1 hr. the soln. became yellowish brown and, after 4 hrs., a slight black ppt. appeared, while the supernatant liquid remained brown in color. Sb and K tartrate gave no ppt. or coloration even after 4 hrs. Sb_2S_3 in 10 min. gave a slightly brown coloration which gradually became more intense and turned to brownish red in 1 hr.; in 4 hrs. a black ppt. had been produced, while the supernatant liquid was of a brownish color. In order to obtain greater amts. of the ppt. the tests were repeated with 3 g. of the preps. and 30 or 60 cc. of the Bettendorf reagent. The black ppts. which were obtained were washed and introduced separately into the Marsh app., rings (in reduction tubes) and spots (on porcelain) being obtained therefrom. The rings were grayish black in color and showed little luster or uniformity in tint, but appeared to consist of a deposit of a brownish black powder. The rings slowly disappeared when heated in a current of H; when heated in a current of air they yielded a white, amorphous, slightly vol. oxide insol. in boiling H_2O or $NaClO$ soln. A current of H_2S passing through the slightly heated tube changed the black color of the ring to orange. No odor was detected when a tube was broken at the ring and heated in a flame. The spots on porcelain were brownish black in color and were insol. in $NaClO$ soln. They dissolved in dil. HNO_3 (sp. gr. 1.2) with production of a white insol. oxide which gave no reaction in the cold with $AgNO_3$ soln. and NH_4OH ; when heated, reduction occurred with separation of Ag. The spots assumed an orange red coloration when moistened with $(NH_4)_2S$ and became sol. in HCl, but insol. in NH_4OH and $(NH_4)_2CO_3$. When exposed to Br vapor the spots became orange colored, but the coloration gradually disappeared on exposure to air; the orange coloration was restored by the action of H_2S . When exposed to I vapor the spots assumed a brownish crimson coloration which changed to orange on exposure to air. The spots were not affected by cold KIO_3 soln.; they gradually dissolved, however, in the hot soln. The substance constituting the spots dissolved readily in Na nitroprusside soln.; this substance was not affected by cold $KClO_3$ soln., but dissolved to a slight extent in the hot soln. The above tests indicate that the ppts. produced by the Bettendorf reagent are to be attributed to Sb and that the presence of As in these ppts. is excluded. Under the conditions of the test the Bettendorf reagent acts upon Sb compds. in a manner strictly analogous to that prevailing in the case of As compds. Certain tests given in the German pharmacopeia for Sb_2S_3 were also applied to all the pharmacopeial preps. tested above. Five-tenths g. of Sb_2S_3 were heated for 2 mins. at 50-60°, with const. shaking, with 5 cc. aq. soln. of $(NH_4)_2CO_3$ (satd. in the cold); the test for As (yellow flocculent ppt.) was given in 6 hrs. when HCl was added to the filtered soln. In order to apply the above test to the other pharmacopeial Sb preps. mentioned above, the latter were converted into Sb_2S_3 and this compd. was dissolved in $(NH_4)_2S$. The filtered soln. was treated with HCl in excess and the collected ppt. (still moist) was digested with $(NH_4)_2CO_3$. After complete digestion the filtered soln. was treated with HCl as in the foregoing test for the presence of As in Sb_2S_3 . No yellow ppt., or even turbidity, was observed with any of the pharmacopeial Sb preps. which

had given a positive reaction with the Bettendorf reagent. A positive reaction with the latter reagent cannot, therefore, without confirmation, be taken as an indication of the presence of As.

H. S. PAINE.

Acetanilide. KAUSERMANN. *Boll. chim. farm.* **54**, 359(1915).—A simplification of the usual procedure (prolonged boiling of AcOH and aniline for 6–8 hrs.) consists in the use of a small amt. of $ZnCl_2$. Pure aniline (75 g.), AcOH (75 g.) and $ZnCl_2$ (3–4 g.) are placed in a flask provided with a reflux condenser; the mixt. is heated to gentle boiling for 3 hrs. after which the product of the reaction is poured into H_2O . The acetanilide separates in cryst. form; it is then washed with H_2O and recrystd. from boiling H_2O .

H. S. PAINE.

Physical and chemical properties of oleoresin of aspidium. Detection of adulterations. A. G. DUMERZ. *Philippine J. Sci.* **8**, 523–38(1913).—The color of the ext. prepared from fresh rhizomes is yellowish green; that prepared from old material is brownish in color. Adulteration with chlorophyll or with Cu salts colors the ext. deep green; the former may easily be detected by the depth of color, the latter in the usual manner. Adulteration with castor oil lowers the sp. gr. of the ext., index of refraction, I and sapon. values. Its presence can most easily be confirmed by solubility tests. The presence of aspidin indicates the use of *Aspidium spinulosum* in the prepn. of the ext. in place of male fern. I and sapon, nos. vary with the filicin content and hence the detn. of these might be used instead of the rather long and expensive filicin assay. Ether is found to be superior to acetone as the extn. medium since the latter yields a product which seps. in 2 layers.

BERNARD RAYMUND.

Vanillin. M. LEHMANN. *Chem. Ztg.* **39**, 266(1915); cf. *C. A.* **8**, 2218.—A reassertion of statements in the previous article that vanillin from clove oil is purer than that prepd. from guaiacol; an answer to Boehringer and Söhne (*C. A.* **9**, 1365).

NORMAN A. SHEPARD.

Eudesmin and its derivatives. I. ROBERT ROBINSON AND HENRY G. SMITH. Univ. Sydney, Australia. *Proc. Roy. Soc. N. S. Wales* **48**, 449–63(1915); cf. *Chem. Zentr.* **1896**, II, 122.—Eudesmin, $C_{22}H_{36}O_6$ (a), is obtained, mixed with aromadendrin, from the kino of *Eucalyptus hemiphloia* by repeated extn. with Et_2O . A thick syrup is first prepd. by treating the pulverized kino with hot H_2O . (a) is extd. from the aromadendrin by treating the cryst. residue, obtained on evapn. of the Et_2O , with cold $CHCl_3$; prismatic needles or (occasionally) leaflets from MeOH, m. 107° . (a) may also be extd. from the kino directly with $CHCl_3$, when it is obtained unmixed with aromadendrin. The air-dried kino contains about 10% (a). The latter may be distd. *in vacuo*; $[\alpha]_D^{21}$ in $CHCl_3$ -64.4° . In H_2SO_4 with veratrole, it gives an intense crimson coloration. (a) is unchanged by boiling alc. KOH, NH_2OH , NH_2NH_2 , $PhNHNH_2$, $NH_2NHCONH_2$, $PhNH_2$, $AcCl$, $BzCl$, $PhNCS$, or hot Ac_2O and $AcONa$, indicating the absence of both CO and OH groups. It is recovered unaltered after treatment with Na-Hg in aq. alc. or by H in the presence of Pd; Br substitutes, but does not add. These reactions lead to the conclusion that (a) is satd. Oxidation with $KMnO_4$ gives a small amt. of 3,4-(MeO) $_2$ $C_6H_3CO_2H$. 5.0 g. (a) in 25 cc. AcOH, treated cold with a mixt. of 10 cc. HNO_3 (d. 1.42) and 15 cc. AcOH, gives a ppt. of dinitroeudesmin (b) in about 5 min.; almost colorless, slender needles from $AcOEt$, m. 214° . (b) may also be formed from (a) with cold 30% HNO_3 . It becomes yellow on exposure to light and gives a bright red soln. in H_2SO_4 . 1.0 g. (a), boiled for 10 min. with 10 cc. concd. HNO_3 , then dild. with H_2O and the ppt. recrystd. from alc., gave 4,5-dinitroveratrole (c); $(CO_2H)_2$ was found in the HNO_3 soln. On the assumption that (a) contains only one veratrole nucleus, the yield of (c) was larger than theoretical, but calcd. for two such rests, the yield corresponded to 90% of the theoretical value. This also accounts for the 4 MeO groups, for which (a) analyzes by the Zeisel method. Dichloroeudesmin

(d) is pptd. when Cl is passed into a well cooled soln. of 5.0 g. (a) in 50 cc. AcOH for 0.5 hr.; needles from AcOH, rectangular plates from AcOEt, m. 163° . In like manner, (a) treated cold with Br in AcOH gives *di bromocudesmin* (e), prismatic needles from AcOH, m. 172° , $[\alpha]_D^{22}$ in CHCl_3 69.4° . I does not attack (a); ICl, in AcOH, is used to produce *diiodocudesmin* (f). 5.0 g. (a) in 50 cc. AcOH is heated with 6.4 g. ICl in 50 cc. AcOH for 0.5 hr., decolorized with H_2SO_4 and the sticky residue dissolved in AcOH. This soln. slowly seps. needles, sol. in AcOEt, m. 175° . (e), oxidized by 3% KMnO_4 at 50° , is converted into *6-bromo-3,4-dimethoxybenzoic acid*, unmixed with any isomide. This fact, together with the formation of (c), indicates that both veratrole rests are linked at the 4-position, and (a) may be represented by $[\text{3,4}-(\text{MeO})_2\text{C}_6\text{H}_3]_2\text{C}_6\text{H}_3\text{O}_2$. Halogen and NO_2 groups in (b), (d), (e) and (f) are in the 5,5'-positions. Since (a) gives none of the reactions of the CO or the OH groups, R. and S. assume that the O in the remainder of the mol., $(\text{C}_6\text{H}_5\text{O}_2)_2$, must be linked as in ether and provisionally assign to (a) the

structure $(\text{MeO})_2\text{C}_6\text{H}_3\text{CH.O.CH—CH}_2$

although there is at present no evi-

dence to indicate the position of attachment of the veratrole rests or the relative positions of the two furane rings.

NORMAN A. SHEPARD.

The butyl ester of butyric acid occurring in some eucalyptus oils. HENRY G. SMITH. Sydney, Australia. *Proc. Roy. Soc. N. S. Wales* **48**, 464–8(1915).— PrCO_2Bu , found only in small amts. in most eucalyptus oils, occurs in some quantity in the oil of *E. perriniana*, both from Tasmania and N. S. Wales. This ester was identified by subjecting the fraction from the crude oil b. below 190° to sapon., the PrCO_2H being identified through its Ba and Ca salts, while BuOH was estimated by oxidation with $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 to PrCO_2H . That this ester constituted the greater portion of the total ester is shown by a comparison of the sapon. nos. of the crude oil and the fraction b. below 190° . PrCHO , present in most crude Eucalyptus oils, may be the precursor of this ester.

NORMAN A. SHEPARD.

The phenols occurring in some eucalyptus oils. ROBERT ROBINSON and HENRY G. SMITH. Univ. Sydney, Australia. *Proc. Roy. Soc. N. S. Wales* **48**, 518–9(1915).—Phenolic substances usually entirely absent or occurring only in traces in the essential oils of the various species of *Eucalyptus* have been obtained from *E. linearis* and *E. risdoni* in sufficient quantity to be isolated and described. *Tasmanol*, extd. from these crude oils by shaking with NaOH, b. $268\text{--}73^{\circ}$, inactive b_{44} 175° , d_{20} 1.077, n_D^{22} 1.5269, optically inactive, sol. in NH_3 , partly sol. in Na_2CO_3 , insol. in NaHCO_3 , contains 1 MeO group and appears to have 2 OH groups in *p*-positions. *Tasmanol*, which gives a persistent deep red color with alc. FeCl_3 , appears to be associated with the cineolpheallandrene oils; another phenol, which gives a green coloration with FeCl_3 , is found in certain phellandrene-free species.

NORMAN A. SHEPARD.

Method of preserving potassium iodide solutions. J. BOUYER. *Bull. soc. pharm. Bordeaux* 1914, Aug.-Dec.; *Reper. pharm.* **27**, 143–4(1915).—B. renders the iodide soln. slightly alk. with $\text{Mg}(\text{OH})_2$. This permits the keeping of iodide solns. in clear glass bottles, even in the light, without danger of decompn.

J. W. SHIPLEY.

Tests for hashish. WM. BEAM. Wellcome Trop. Res. Labs., Chem. Section *Bull.* No. 3, 2 pp.(1915).—The ordinary ext. of *Cannabis indica* of the Brit. Pharm. responds only very feebly to the ordinary test for hashish (the production of a rich purple color upon the addition of caustic alkali to a petroleum ether ext. of the substance). Tests on different samples grown in Greece, Egypt, Sudan, India, and Uganda gave negative as well as positive tests, showing that the influence of soil, climate, method of cultivation and curing was very great. An apparently characteristic test is obtained by making a petroleum ether ext. of the sample and evapg. it to dryness. The residue

is treated with abs. alc. satd. with dry HCl. In presence of *Cannabis* ext. a bright cherry-red color develops; this disappears on diln. with alc. or water. The same color is developed by H_2SO_4 in acetone or acetic acid solns. of the ext. Of the 200 alkaloids or plant exts. tested, not one responded to this test, although certain volatile oils (origanum and santal) gave a similar reaction but developed a far less intense color for similar amts. of material.

R. L. SIBLEY.

Pills and granules of pharmaceutical manufacture. M. FRANÇOIS. *J. pharm. chim.* 11, 275-9(1915).—Large scale prepn. in mass, *e. g.*, of 2,000,000 granules each containing 1 mg. strychnine sulfate, does not give uniform results. Even a mass of only 200 granules of As_2O_3 with flour as base, triturated by hand for a long time, when divided into 4 equal parts, assayed 0.0487, 0.0503, 0.0526 and 0.0487 g. As_2O_3 . Official granules should be prepared in mass of not over 200, with the excipients directed by the codex.

S. WALDBOTT.

Sulfates of magnesium and of sodium in plaster of Paris. E. CANALS. *J. pharm. chim.* 11, 286-90(1915); cf. C. A. 9, 1368.— $MgSO_4$ and Na_2SO_4 occurred in nearly all plasters examd., $MgSO_4$ varying from 0.13 to 0.981% and Na_2SO_4 from 0.10 to 0.97%; surgical plasters had but traces. Both salts hasten the setting, Na_2SO_4 more rapidly than $MgSO_4$. One % $MgSO_4$ reduced the time of setting from 30 min. for pure plaster to 21 min.; 1% Na_2SO_4 to 12 min. The temp. is raised only by 12.1° with a mixt. of 1% of each salt. The use of these salts is recommended for surgical dressings in the place of alum or NaCl. Cf. C. A. 8, 1328.

S. WALDBOTT.

Frangula substitutes, the barks of Rhamnus carniolica A. Kerner, and *Alnus glutinosa* Gaertn. O. TUNMANN. *Schweis. Apoth. Zig.* 53, 313-8, 325-32(1915).—Microscopically (cf. Mitlacher, *Z. allgem. Oest. Apoth. Ver.* 1906), the *Rhamnus* barks differ chiefly in the breadth of their medullary rays; those of *R. carniolica* are broadest (4-6, even 8 rows), of *R. frangula* the narrowest (1-2, seldom 3 rows). Anthraquinone derivs. are yielded by microsublimation of 0.001 g. of powdered dried bark in decreasing amts. from *R. carniolica*, *frangula*, *Purshiana* and *cathartica*. *R. carniolica* also yields large crystals by this and the EtOAc methods (C. A. 9, 476, 1660). It is a legitimate substitute for *R. frangula*; *Alnus glutinosa* is a worthless adulterant (L. Würfel, *Z. allgem. Oest. Apoth. Ver.* 1907). In chem. exam., emodin was extd. from all species of *Rhamnus* named; chrysophanol occurred only in *R. frangula* and *R. cathartica*, not in *R. purshiana* or *R. carniolica*. The latter showed small amts. of cinnamic acid by microsublimation. Cork cells and the rough outer bark of some *Rhamnus* species are free from anthraquinone derivs. The assay methods for *R. frangula* are reviewed. To assay *R. carniolica*, the gravimetric method of F. Daels (C. A. 7, 4042) is modified to det. only total anthraquinone derivs. Two specimens yielded 3.32 and 3.78%.

S. WALDBOTT.

Substitute for mucilage. BERGER. *Schweis. Apoth. Zig.* 53, 321(1915).—Dissolve the residues in the prepn. of tinct. of myrrh in twice their wt. of H_2O and strain through cloth; the soln. is a useful mucilage.

S. WALDBOTT.

Bismutum subnitricum containing chloride. FLEISSIG. *Schweis. Apoth. Zig.* 53, 341(1915).—A com. sample was yellowish, dissolved incompletely in 10% H_2SO_4 , almost entirely in 30% H_2SO_4 . It did not make a clear soln. with HNO_3 , and gave an abundant ppt. with $AgNO_3$.

S. WALDBOTT.

Transformation of antipyrine into diantipyrylmethane by means of formaldehyde. CHARLES ASTRE. *Bull. soc. chim.* [4] 17, 175-9(1915).—A. criticizes Patein's method for the detn. of antipyrine (A) in the presence of pyrimidone (B) (cf. *Ibid* [3] 33, 846) and suggests modifications. (A) may be rapidly and quant. converted into diantipyrylmethane by means of aq. HCHO free from all traces of alkali. The reaction may

be satisfactorily carried out in a boiling H_2O bath, in Pt pressure bottles or in glass bottles which have been thoroughly rinsed with hot HCl. Traces of alkali yielded by the glass containers are sufficient to retard the reaction and to render it incomplete even after 32 hrs. In the presence of (B), no reaction whatsoever takes place between (A) and $HCHO$, but the reaction proceeds normally provided (B) is first neutralized with HCO_2H , using helianthine as indicator. Under these conditions it is possible to estimate the amt. of (A) present in an (A)-(B) mixt. LOUIS E. WISE.

Commercial chrysarobin (EDER) 10. Determination of methyl alcohol in presence of ethyl alcohol (WILKS) 7. Use of adsorptive capacity of talcs and kaolins in the perfume industry (ROHLAND) 27. Detection of methyl alcohol in ethyl alcohol (PAZIENTI) 7.

U. S., 1,143,114, June 15. G. P. FULLER. Formaldehyde solution is made from polymerized CH_2O by mixing it with 3 to 4 times its wt. of H_2O and with 0.0005 to 0.003 of a mol. proportion of Na_2SO_3 . The latter may be separately added at the time of making up the soln. or a dry mixt. of polymerized CH_2O with Na_2SO_3 may be made for use as desired to avoid expense in transport and storage of CH_2O in the form of its aqueous soln. The Na_2SO_3 acts as an active catalyzer in promoting solution of the polymer.

U. S., 1,144,141, June 22. J. LAGUTT. Acid ferrocyanides of dimethyl-*p*-aminophenol and *p*-hydroxyphenyltrimethylammonium are made by adding $K_4FeC_6N_6$ to a soln. of $p-Me_2NC_6H_4OH$ and $p-HOC_6H_4Me_2N$ compds. (obtained by methylating $p-NH_2C_6H_4OH$) acidulated with H_2SO_4 , dissolving the pptd. compds. in NaOH and $Na_2S_2O_4$ soln. extg. the $Me_2NC_6H_4OH$ with C_6H_6 and recovering the base from the C_6H_6 by adding H_2SO_4 and finally acidifying the residual soln. to effect pptn. of the ferrocyanide, which seps. as shining yellowish white plates.

U. S., 1,144,237, June 22. W. H. PERKIN, C. WEIZMANN and H. DAVIES. Dihalogen derivatives of saturated hydrocarbons, *e. g.*, dibromoisopentane, are made by reacting on vapors of monochloro derivs., *e. g.*, isoamyl bromide or chloride with halogen which is supplied at such a rate that it is immediately used up in the reaction when it comes into contact with the vapors. By thus avoiding an excess of Cl at any time, the formation of tri- and tetrahalogen compds. is minimized. Cf. C. A. 8, 1190.

U. S., 1,144,270, June 22. R. F. VON WALTHER. 6-Chloro-1-methyl-3-hydroxybenzene-4-carboxylic acid is made by heating dry Na *p*-chloro-*m*-cresolate under a pressure of 5 atm. in CO_2 to 160° . The product is suited for use as a disinfectant. From H_2O it forms needles and from alc. flat prisms. It m. 205° .

U. S., 1,144,558, June 29. F. E. MATTHEWS and H. J. W. BLISS. 2,3-Dichloro-3-methylbutane is made by heating vapors of 1,2-dichloro-3-methylbutane at $324-36^\circ$. The product is subjected to fractional condensation and the unconverted portion returned for further treatment.

U. S., 1,144,829, June 29. G. FENDLER. Extracting egg yolks with acetone. See Ger., 272,057 (C. A. 8, 2459).

Brit., 5,369, Mar. 3, 1914. E. W. LUCAS and J. S. HILLS. A prepn. to be used in wet poultices and dry packs consists of kieselguhr, mixed with volatile oils or oleoresins, such as oil of turpentine and ext. of capsicum, or with substances yielding volatile oils or oleoresins, such as mustard or capsicum. An antiseptic such as Na_2BO_3 may be added.

Brit., 5,408, Mar. 3, 1914. H. HIBBERT. Prepn. of mesityl oxide from diacetone-alcohol, of dimethylbutadiene from pinacone, and of tetrahydrobenzene from cyclo-

hexanol. These and other reactions in which 1 or more mols. of H_2O are removed from a single mol. of an organic compd. are effected in the presence of small quantities of I with or without the use of reduced pressure.

Brit., 5,773, Mar. 6, 1914. R. MÜLLER and DEUTSCHE CELLULOID FABRIK. Organic acid anhydrides, mixed or not with the corresponding acid, are prepd. by passing N_2O_4 alone, or other N oxides mixed with air or O, over dry salts of organic acids in the solid state or dissolved or suspended in inert liquids. The resulting anhydride may be freed from the nitrate formed by heating *in vacuo*, or by extrn. Mixts. of acetates, butyrates, propionates, etc., give mixed anhydrides.

Ger., 281,148, Nov. 28, 1911. E. LANGER. In the manuf. of a readily sol. stable disinfectant for the prepn. of a mouth wash and rinsing water, preparing exact portions, in tablet form, of the strongly disinfecting and bactericidal NaF and Na_2SiF_6 , rendered stable by admixt. with tartaric acid and Na_2CO_3 or $NaHCO_3$, equivalent in strength to a 0.1% sublimate soln. E. g., 30 parts Na_2CO_3 or $NaHCO_3$, 15 of Na_2SiF_6 or NaF, and 15 of tartaric acid are ground separately with alc. to which have been added the oils, and the like, to render the product palatable, together with a small amt. of soap as an emulsifying agent. The alc. is then expelled by drying, all the constituents are intimately mixed, as by bolting, and compressed to tablets of 0.6 g. each. If only 5 parts of NaF are used, from 5 to 10 parts of succinic acid are added. The tablets are dissolved in H_2O or may be allowed to dissolve in the saliva.

Ger., 281,547, Dec. 4, 1913. Addition to 257,138 (C. A. 7, 2455). H. DECKER. In the manuf. of hydrohydrastinine, employing polymerized HCHO (in the presence of a solvent or diluent) instead of aq. HCHO soln., as specified in the principal patent. The operation can then be carried out in an open vessel and at temps. above 100° .

Ger., 281,553, July 4, 1911. G. A. RANFT. In the evolution of formaldehyde gas or the production of aq. HCHO solns. from polymerized HCHO, the latter is heated in admixt. with H_2O and an alkali or alk. earth chloride, or mixts. thereof, in open vessels, or heated H_2O , or steam, is conducted through the mixt. By means of a boiling soln. of 20 g. $CaCl_2$ in 100 cc. H_2O , a mixt. of 30 g. trioxymethylene is converted quant. into an aq. HCHO soln., and simply by warming on the H_2O bath a very general depolymerization results. If steam be blown through a mixt. of 15-30 g. $CaCl_2$ and 30 g. paraformaldehyde, HCHO gas is formed.

Ger., 281,603, July 9, 1912. CHEM. FABRIK AUF AKTIEN (v. E. SCHERING). Tasteless homologs and substitution products of 2-piperonylquinoline-4-carboxylic acid are obtained by condensing homologs or substitution products of aniline (e. g., *p*-toluidine, *p*-aminophenol, *o*-anisidine) with piperonal and pyroracemic acid, in the usual manner. Cf. C. A. 8, 2780.

Ger., 281,801, Dec. 5, 1913. F. HOFFMANN-LA ROCHE & Co. Mfg. lipid compounds containing phosphorus from high molecular fatty acid derivatives by allowing H_3PO_4 , alone or in soln., to act upon higher mol. keto fatty acids and their derivs. E. g., 30 parts 10-ketostearic acid (from stearyl acid) are boiled with 15 parts crystd. H_3PO_4 and 30 parts glacial HOAc, under a reflux condenser with external temp. of 160° . Or the hydroxyphosphinic acids, or their derivs., obtained according to 280,411 (C. A. 9, 1372) from the higher mol. keto fatty acids and their derivs., are treated with mild oxidizing agents, and the free acids are converted into the salts in the usual manner. E. g., hydroxystearinphosphinic acid is mixed. in alc. soln. with warm alc. $HgCl_2$ soln.

Ger., 281,802, Aug. 3, 1913. H. LECHER. In mfg. aromatic or fatty aromatic hydrocarbons or ketones, instead of $AlCl_3$ as catalyzer, ordinary com. P_2O_5 is employed, at $150-200^\circ$ in splitting off the HCl; e. g., for the production of benzophenone,

0.2-0.3 parts of P_2O_5 , 14 of $BzCl$, and 30 of C_6H_6 , are heated in the autoclave up to 200° .

Ger., 281,902, Sept. 18, 1913. J. D. RIEDEL, AKT.-GES. Splitting off water from hydroxy compounds by distn. of the substances, such as glycerol, tartaric acid, terpineol, together with glycollic acid or glycollide, under the ordinary or reduced pressure. In this manner secondary reactions are prevented and foaming is reduced, since glycollic acid and glycollide act as solvents or diluents.

Ger., 281,912, Apr. 3, 1913. F. HOFFMANN-LA ROCHE & Co. Mfg. acyl compounds from *p*-hydroxyphenylethylamine and 2-imidazolylethylamine by coupling the amines or their hydrochlorides, such as in alk. soln. with halogenacyl chlorides, as chloroacetyl, bromopropionyl chloride, and treating the resulting halogenacylamines with NH_3 . The aminoacylamines so obtained are less poisonous than the amines themselves.

Potash salts, 1914. W. C. PHALEN. U. S. Geol. Survey, *Separate from Mineral Resources of U. S. 1914*, Part II, 25 pp.—Production statistical. Cf. C. A. 8, 3706.

R. S. MCBRIDE.

Potash from kelp. FRANK K. CAMERON. Bur. of Soils, U. S. Dept. Agr., *Rept.* No. 100, pp. 122, plates 40(1915).—The report consists of 5 parts as follows: I. **Pacific kelp beds as a source of potassium salts.** FRANK K. CAMERON. pp. 9-32.—C. discusses sources of supply of potash, especially the German deposits, and shows the amt. of various potash salts received into this country during the 12-month periods ending June 30, 1912, and 1913, resp. The desirability of an American source of potash is dwelt upon and the investigations along this line referred to. Chief among these investigations is that on the various species of kelp. A comparison of the potash and other constituents occurring in leaves and stems is given, but nothing further than a tentative conclusion is justified. There is a final discussion concerning the commercial side of the kelp question. II. **The kelp beds from Lower California to Puget Sound.** W. C. CRANDAU. pp. 33-49.—A survey is given of the kelp groves in the region, along with observations on the growth of different varieties. III. **The kelp beds of Puget Sound.** GEORGE B. RIGG. pp. 50-58.—This investigation was along the same line as that described in Part II. IV. **The kelp beds of Southeast Alaska.** T. C. FRYE. pp. 59-72.—Discussion similar to that of II, and III. V. **The kelp beds of Western Alaska.** pp. 105-22.—Weather and harbor conditions are given, how beds were mapped, etc. Similar to Parts I, II, III and IV. B. E. B.

The production of potash in California. T. H. NORTON. *Mining Eng. World* 42, 1159-61(1915); cuts.—A brief description of the production of K_2O from the Pacific coast kelp. The salines of Searles lake and the alunite of Utah are touched upon.

F. W. SMITHER.

The solidification of concentrated magnesium chloride liquors. H. HOF. *Chem. Ztg.* 39, 15(1915).—Hof points out that his process (C. A. 8, 2924) differs from that of Forcke (C. A. 8, 3706) in that the solidification is brought about by the conversion of calcined $MgSO_4$ to $MgSO_4 \cdot 4H_2O$, whereas Forcke's process depends upon the formation of $MgO \cdot MgSO_4$, the latter salt being produced by the partial decompn. of $MgCl_2$ in the process of heating the conc. liquors with residues (containing $MgSO_4$) from the leaching tanks. Hof admits that $MgSO_4 \cdot 4H_2O$ and not $MgSO_4 \cdot 7H_2O$, as originally stated, is formed in his process.

A. F. SEEKER.

The waste liquor question of the potash industry. BERGER. Bunzlau. *Z. angew. Chem.* 27, 1, 660-2(1914).—It is shown how the problem of disposing of the enormous amt. of end liquors containing $MgCl_2$ embarrasses potash works. Permission to run them into streams is no longer granted by the authorities and the consumption of $MgCl_2$ concentrates for road sprinkling, for the textile industry, and for the manuf. of cement floors is extremely small as compared to the output. Ger. patent 278,106, which provides for the manuf. of MgO and HCl by heating an infusible mixt. of $MgCl_2$ and $MgO \cdot MgCl_2$ in a rotary tube furnace, appears to offer the most hopeful way out of the difficulty, provided a sufficient market can be created for the disposal of $MgO \cdot MgCl_2$ into which, for economical reasons, part of the waste liquor concentrate must be converted by means of the MgO obtained in the first operation. Possible uses for $MgO \cdot MgCl_2$ are: the manuf. of cement floors, for clarifying factory waste liquors, as an absorbent for disinfectants like phenol and tar oils, for conditioning the soil in dry regions; and making it hygroscopic, and for transporting to the tropics where it can be converted into HCl by heating, this being a much more convenient procedure than transporting the acid itself. A return of 1.2 to 1.5 marks per 100 kg. for $MgO \cdot MgCl_2$ would enable technically As-free HCl of 20° Bé. to be delivered at the works for 1 mark per kg.

A. F. SEEKER.

Chemical analysis of the mother liquors of the salt-mine of Comacchio. MARIO ASQUINI. Padova. *Ann. chim. applicata* 3, 284-95(1915).—The analysis, expressing the components as ions, in grams per kg. H_2O at 16° was as follows: Na 49.858, K 3.952, Ca 0.301, Mg 13.362, Fe 0.0243, Al 0.00008, Li 0.00007, Ba 0.00223, Sr 0.00216, NH_4 0.00092, Cl 105.213, Br 0.621, SO_4 19.501, I 0.00003, BO_3 0.00371, HCO_3 0.15212, totaling 192.991 g. The direct detn. of residue at 160° was 193.809. Li was detd. spectroscopically as follows: 500 cc. of the H_2O were evapd. on the salt bath with excess of pure Na_2CO_3 . The residue was digested with EtOH, the alc. soln. evapd., and the residue taken up with a mixt. of abs. EtOH and Et_2O . Mg was pptd. with CaO and the Ca sepd. by $(NH_4)_2C_2O_4$. The NH_4 salts were driven off by ignition and the residue dissolved in 5 cc. H_2O , slightly acidulated with HCl . Then the liquid was successively dild. until the Li line α disappeared in the spectrum, and this limit found from known titrated solns. of $LiCl$.

S. LEVY.

Preparation of sodium hypochlorite. MARIO RICCI. Rome. *Ann. chim. applicata* 3, 282-4(1915).—Criticism of the paper of Cattania and Ranucci (*C. A.* 9, 1670), calling attention to arithmetical and other errors. It is shown that the percentages of active Cl given are impossible, that deposition of $NaCl$ would not take place when indicated, and that its gradual removal even if deposited would not tend to prevent decomp. of the $NaOCl$, because artificial addition of $NaCl$ to a $NaOCl$ soln. has absolutely no effect in causing decompn., which depends only upon the concn. of the OH and OCl ions, upon the temp., and upon light.

S. LEVY.

Ammonia as a gas for filling air ships. A. SANDER. Darmstadt. *Chem. Ztg.* 39, 325-6(1915).— NH_3 having been proposed as a noncombustible gas for filling balloons, S. points out that not only does it form explosive mixts. with air (16.5 to 26.8% by vol. of NH_3) but that on a basis of buoyancy it costs ten times as much as H, requires a special envelope to prevent corrosion of the fabric, has an extreme tendency to absorb moisture when passing through clouds or mist, is likely to suffocate the operators, and necessitates the use of an envelope of more than double the size of that required for a vol. of H of the same lifting power.

A. F. SEEKER.

The manufacture of hydrogen for inflating balloons. A. FOURNIOLS. *Rev. gén. sci.* 26, 339-45(1915).—A review of the methods that have been proposed for the com. production of H. The hydrogenite, hydrolith and silicol processes are discussed at

some length with cuts illustrating app. for field use. Cf. Jaubert, *C. A.* 8, 477; Seeker, *C. A.* 8, 3619. F. W. SMYTH.

Substitutes in industry, commerce and trade. C. KIPPENBERGER. *Ber. pharm. Ges.* 24, 495-526(1914); 25, 32-63(1915).—An address, first taking up the project for the Brazilian coffee valorization and later dealing with substances and commodities more commonly used as substitutes or surrogates, which for convenience of treatment are divided into 4 groups: (1) indigo, diamond, caoutchouc, etc.; (2) oleomargarin, artificial silk, artificial semi-precious stones, etc.; (3) lupines, chicory, artificial wool, alloys, medicaments, etc.; (4) alc.-free beer, soft drinks, etc. W. O. E.

Transportation of dangerous articles on vessels. *Commerce Reports* 158, 115 (1915).—A summary is given of rulings made by the United States Steamboat Inspection Service with reference to the transportation on passenger vessels of thermit, fuming H_2SO_4 , "Kilsum" insecticide, "Luxo" flash powder and "Sun" metal polish. U. S., 1,142,795, June 15. R. B. LLOPART. **Zinc sulfate** is made by heating a mixt. of blende containing sulfides of Fe and Zn with ZnO or $ZnCO_3$ or calamine to 400-500° in an oxidizing atm. Strong air currents are not allowed to come into contact with the material during the heating. The product is leached with hot H_2O and the $ZnSO_4$ obtained is suited for the manuf. of lithopone. Cf. *C. A.* 9, 1849.

U. S., 1,143,132, June 15. S. PEACOCK. **Fixing atmospheric nitrogen.** A mixt. of Al_2O_3 with a sufficient excess of C to prevent the formation of CO_2 during the process is fed into an inclined rotary kiln and as the mixt. travels through the kiln a burning mixt. of oil or C injected with air is passed through the kiln in the same direction. Free N is fixed by combining with the Al_2O_3 to form $Al_2C_2N_6$, Al_2N_3 and $Al_2(CN)_6$. CaO or SiO_2 may also be used as fixing agents.

U. S., 1,143,343, June 15. J. C. WOODRUFF. **Nickel hydroxide** is made by treating a 1% soln. of $Ni(NO_3)_2$ at 90° or higher with the theoretical amt. of NH_4OH to effect the pptn. Complete pptn. of flocculent hydroxide (suited for reduction on an inert support to form a catalyzer) is effected.

U. S., 1,143,366, June 15. F. W. DEJAHN. **A catalyzer for use in the synthetic production of ammonia** is made by reducing NiO on pumice, with H at 550°, adding a small amt. of metallic Na and heating in anhydrous NH_3 to 450°. With this catalyzer, a yield of 4.5% of NH_3 is obtained from H and N under 80-90 atm. pressure at 520-40°.

U. S., 1,143,482, June 15. A. BADIN. **Aluminium nitride** is made by passing a mixt. of bauxite 30 and C 12 parts through a coal dust flame fed with just sufficient air to produce CO to the nearly entire exclusion of CO_2 by the combustion.

U. S., 1,143,614, June 22. B. H. CRISWELL. **Mixture for cleaning glass**, etc., composed of $NaCl$, $MgSO_4$, oleic acid, petrolatum, NH_4OH , glycerol, tripoli, whiting and H_2O . This mixt. is used to impregnate cloth used to scour the glass.

U. S., 1,143,621, June 22. W. L. GEDDES. Fiber-board is made from the residue obtained in making ext. of licorice root, after treating the residue with NaOH to remove resin and non-cellulosic constituents, and washing.

U. S., 1,143,622, June 22. G. GERDOM. Plastic mixture for making the cores of obturators of breech-loading ordnance; formed by mixing tung oil 10, tallow 14, petroleum jelly 7 parts, after separately heating to 205° and then incorporating about 17 parts of finely shredded asbestos after the mixt. has cooled to about 120°. When cold, the mixt. is pressed into the required form.

U. S., 1,143,625, June 22. I. HECHENBLEIKNER. Liquid calcium nitrate is collected in small molds, each of which is cooled by H₂O around the mold to cause solidification of the nitrate into cakes. The latter are then broken up by a coarse crusher and pulverizer while passing an air blast over the material to prevent undue heating and the finely divided nitrate produced is carried to the point of collection on the air blast.

U. S., 1,143,893, June 22. R. DODD and H. B. P. HUMPHRIES. A plastic material from soy bean. See Brit., 15,316, 1913 (C. A. 9, 132).

U. S., 1,143,952, June 22. H. FREEMAN. High-grade cyanide, *e. g.*, NaCN, is made by treating the crude cyanide in soln. with Fe(OH)₂ and heating to form ferro-cyanide, purifying the latter by crystn. and then converting it back to cyanide by heating on a bath of molten Pb with Na or other metal corresponding to the cyanide under treatment.

U. S., 1,144,338, June 22. J. W. AYLSWORTH. Matrix for forming fac-similes of intaglio or relief plates, half tones, set type, etc., formed of hard infusible condensation product of PhOH with CH₂O and (CH₃)₂N₂.

U. S., 1,144,457, June 29. C. BEINDL. Cyanogen is made by passing a mixt. of NH₃ and C₂H₂ over a network of wire formed of Ag, Au, Ir, Pd, Rh, Co, Cr, Cu, Fe, Mn, or alloy of Cu and Zn, heated to 480°. Nitrides may also serve as catalysts. The gases from the reaction are absorbed with NaOH soln. Cf. C. A. 9, 1981.

U. S., 1,144,730, June 29. K. SCHAEFER. Producing hydrogen. Reducing gas

and steam are alternately supplied through the pipes 16 and 12, resp., to a filling of tubular Fe rods and loose pieces of Fe, b and b₁, within the chamber. The outer portion of the Fe filling is composed of smaller pieces than the central portion to equalize the flow of the gases. The H is drawn off through the pipe 18.

Brit., 5,145, Feb. 27, 1914. NORSK TANGSYNDIKAT. Leaching seaweed with H₂O at a temp. not exceeding 50°, the direction of flow of the H₂O being opposite to that of the weeds. The lye is evapd, at a reduced pressure, preferably lower than half an atm. The product contains I compds., Mg compds., mannitol, mucous substances, and "kreftin," a substance considered to be a carbohydrate, of the formula $nC_6H_{10}O_6 + mH_2O$. The ingredi-

ents may be sepd., or the product used in the prepn. of baths for the treatment of rheumatism and skin diseases.

Brit., 5,146, Feb. 27, 1914. **NORSK TANGSYNDIKAT.** Alginates are obtained from the stalks of seaweeds by removing the outer skin by grinding, cutting, or other mechanical means, cutting the stalk into small pieces, leaching with warm H_2O , bleaching, and finally extg. the desired substance with chemicals in the known manner.

Brit., 5,147, Feb. 27, 1914. **J. S. LUCOCK.** An anti-rust composition for maintaining the brightness of steel and other metal surfaces consists of liquid paraffin, starch, and alum. The starch and alum are mixed with H_2O , the H_2O is evapd., and the residue is mixed with the paraffin at about $110^\circ F$. The liquid is strained when cool.

Brit., 5,798, Mar. 7, 1914. **E. N. LAINE.** Purifying natural graphite. The graphite after preliminary purification and classification by mechanical means, is washed first with dil. acid, then with H_2O , and dried; it is then intimately mixed with alkali or alkali carbonates, such as Solvay soda, a mixt. of Na_2CO_3 and K_2CO_3 , or $NaOH$, and heated to a high temp., preferably 1050° ; the product is then washed first with H_2O , then with dil. acid, and finally with H_2O , and dried. HCl is the acid specified.

Brit., 5,830, Mar. 7, 1914. **E. HOWL and F. PERRY.** Recovering sulfuric acid from waste pickle by concg. to such a degree that substantially the whole of the $FeSO_4$ is pptd. in the anhydrous form.

Brit., 5,859, Mar. 7, 1914. **V. HERENG.** Artificial lithographic stones are made by a process similar to that described in 12,640, 1913 (*C. A.* 8, 3706), with the addition of white sand to the other materials used, namely cements, oölitic limestone, and trass, these materials being mixed in somewhat different proportions to those given in the principal process. A mixt. of 3 parts of cement and 1 part each of limestone, trass, and white sand is sifted, mixed, and compressed in a mold formed with fine perforations, and is left in H_2O for a day and then submitted to the action of the air for about 2 days. The stone is then placed in H_2O for 4 months in a cool chamber free from the action of air currents. Cf. *C. A.* 8, 2787.

Fr., 468,535, Apr. 26, 1913. **L. C. BONNEAU and V. E. HASENFRATZ.** In the treatment of crude ammonium salts, after the drying and removal of the S by means of C_2HCl_3 , the material is subjected, in a diffusion battery, to extrn. by means of condensed water containing NH_3 from the drier. The residue is worked up, with the aid of hot milk of lime, into $Ca_2Fe(CN)_6$, which can be pptd. by KCl as the double salt.

Fr., 468,879, May 5, 1913. **A. LABBÉ.** In the manuf. of plastic products from dihydroxy- and trihydroxybenzene, resorcinol, hydroquinone, pyrogallol, pyrocatechol, and their derivs. are dissolved in $HCHO$ solns. in the presence of very small amts. of dil. mineral acids which appear to act as catalyzers, whereupon the mass solidifies, after several hrs., to an elastic product, the hardness of which increases with the diln. of the $HCHO$, and which can be rendered transparent by the addition of acetone or glycerol to the $HCHO$. The product is permanent, fireproof, and easily worked.

Ger., 279,474, Oct. 8, 1912. **S. C. BOND.** In mfg. cork products from ground cork, the cork particles are mixed with a binder, pressed in molds, and heated.

Ger., 281,528, Aug. 24, 1913. **ALPINE MASCHINENFABRIK-GES. M. B. H. v. HOLZHAÜßERSCHÉ MASCHINENFABRIK G. M. B. H.** App. for etching metal.

Ger., 281,792, Aug. 30, 1912. **W. HENTSCHEL.** Process of dehydrating alkali lyes, depending upon the observation that completely dehydrated KOH has no oxidizing action on Fe heated to redness, and that this is practically true of KOH with 1% H_2O , while, on the contrary, alkali of 1-4% H_2O content acts energetically on Fe heated to redness. The dehydration of the lyes is effected by allowing them to flow through a system of Fe retorts of different temps., wherein the alkali of 96-99% dehydration

is maintained at a temp. below red heat, while the residual H_2O is removed in retorts heated to redness. The lye is passed in a thin layer over the flat bottoms of the retorts.

Ger., 281,806, June 14, 1913. P. DEGENER and W. BERNDT. **Mummifying stuffed animal and anatomical preparations.** After the specimen has been prepd. for preservation it is treated with $HgCl_2$ as a hardener, then dehydrated in alc. baths of increasing concn., and then immersed in a bath consisting of a volatile hydrocarbon or a deriv. thereof (xylene, $CHCl_3$). The specimen is then immersed in warm (liquid) paraffin and finally in a mixt. of paraffin 3 and light resin (colophonium citrinum) 1. After complete satn. the excess liquid is allowed to flow off and the specimen allowed to cool. By this treatment the milky-opaque, half transparent appearance of the muscles of fish, amphibia, and the like, is simulated on drying. The slimy-transparent luster of the surface is imitated by a layer of resin-alc. varnish. Anatomical specimens may be prepd. in like manner.

Ger., 282,226, Feb. 22, 1913. Addition to 278,868 (C. A. 9, 1096). HENKEL & Co. In mfg. **magnesium perborate**, instead of Mg salts in fusion with alkali perborate, the alkali peroxides can be employed directly, and need not be converted first into the alkali perborates. The Mg salts are mixed with alkali peroxides, borax, and corresponding amts. of substances (of an acid character) to neutralize excess alkali. This mixt. is allowed to take up the necessary amt. of H_2O (about 25%). The mass is then fused at about 60° , with stirring. After the melt has been held at the specified temp. for some time, it is allowed to solidify by cooling. The choice of added bodies is detd. by the purpose for which the end product is to be used. Of the Mg salts, only those are considered whose anions form with the alkali of the peroxide, salts containing H_2O of crystn. E. g., 1 mol. $MgSO_4 \cdot 7H_2O$, 2 mols. Na_2O_2 , and 0.5 mol. borax, are mixed dry with sufficient H_3BO_3 to neutralize the excess alkali. This mixt. is allowed to absorb about 25% moisture, exercising care. The resulting mixt. is allowed to melt on the H_2O at about 65° , and is stirred for some time; it solidifies, on cooling, to a solid cake which is readily comminuted and which can be pulverized after complete drying. By this process, loss of active O is said to be prevented, with the formation of a uniformly high grade product of great stability.

Ger., 282,252, June 1, 1913. R. FLEISCHER. Constructional details of an app. for decomposing and dissolving potassium salts and the like in continuous operation. Cf. C. A. 8, 3225.

Ger., 282,433, Mar. 25, 1914. A. E. STRIPPEL. In the manuf. of a stencil sheet material, long-fibered material is treated with a soln. containing an animal colloid (gelatin), glycerol, a Cr salt ($K_2Cr_2O_7$), and a hygroscopic nitrate ($NaNO_3$). Preferably the following proportions are used: gelatin 450, glycerol 510-620, $NaNO_3$ 42.5, and $K_2Cr_2O_7$ 9-13.6 g. After drying, the material is satd. with a soln. of glycerol alone or of glycerol with alc. and $AlCl_3$, e. g., with 5 parts glycerol, 1 of alc., and 1 of $AlCl_3$. Cf. C. A. 8, 1849.

Ger., 282,489, Mar. 20, 1913. M. LEISTICO. Process of preventing the scum on boiling salt solutions, consisting in adding to the soln. before or during the boiling

process, $MgCl_2$, solid or in soln., or as the end- or mother-liquor from KCl or sulfate manuf. The amt. of this admixt. is detd. by the content of organic substances in the soln., or by the firmness of the scum.

Ger., 282,505, Nov. 19, 1913. BADISCHE. Removing carbon monoxide from gas mixtures by means of ammoniacal cuprous chloride soln. under pressure. The solns. contain, in 1 liter, considerably more than 60 g. NH_3 gas in the form of free base or carbonate. Fe app. or parts in motion are not injured by this soln. so that high pressure can be employed, where stoneware and Pb are not suitable. NH_3 is supplied as it is lost, the soln. is kept in circulation between the absorption and a lower pressure chamber where the CO is removed, and any oxidation of Cu is corrected by the CO before it is removed. A suitable soln. is prepd. by mixing 200 kg. Cu_2Cl_2 , 250 kg. NH_4Cl , 500 kg. 25% NH_4OH , and 500 kg. H_2O . Operating at pressures above 100 atm., very small amts. of CO may be removed from gases (such as H containing CO) in a short time.

Ger., 282,657, Nov. 17, 1911. M. SPETER. In a process for the direct separation of scandium from mixtures with other rare earths, the minerals are decompd. with H_2SO_4 , HCl, or the like, or fused with alkali and then dissolved in acid. The acid soln. is pptd., boiled, with H_3PO_4 , filtered off or expressed, the ppt. again dissolved in H_2SO_4 , and pptd. as oxalate. The crude Sc oxalate differs from the other trivalent earths in that it forms with H_3PO_4 and its salts in acid soln., an insol. compd.

Ger., 282,665, Aug. 31, 1911. H. BARSCHALL. App. for obtaining high percentage oxygen by the rectification of liquid air in counter current to the vapors therefrom. From 100 cu. m. of liquid atm. air, 13-14 cu. m. O, of standard purity, are said to be produced by this app. The liquid air flows within a large number of narrow, long tubes of about 5-9 mm. internal diam. in a small stream, in a downward direction. The tubes are wound helically around a longitudinal axis, and at such an inclination that the flow of liquid air is slow, care being exercised that only liquid flows from the exit so that the vapors always rise counter to the liquid. If a warm gas is allowed to rise in contact with the outer surface of the tubes, the temp. is maintained, at the lower end of the tubes, at about -184° , and the liquid air, during its downward flow, is freed from almost all its N, so that O of a purity up to 99.5% flows out, while the N, with but very little O, passes out at the top of the system (about 7% O). If the O produced is allowed to bathe the outer surface of the tubes, a further purification is effected, and such difficultly removable constituents as A can be sepd.

Ital., 134,253, June 30, 1913. A. KRUMM and A. BONELLI. A solid laundry product consists of a mixt. of $CaOCl_2$ and gelatinous silica.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The pottery industry. U. S. Bur. of Foreign and Domestic Commerce, *Miscellaneous Ser.* No 21(1915).—This rept., prepared with the coöperation of the Bur. of Standards, besides the statistical tables as to costs, wages, numbers of workmen, output, etc., usually found in such documents, contains a great deal of technical matter, covering the origin, compn., and rôle of the various raw materials of the pottery industry in the U. S., England, Austria and Germany. The processes of manuf., the machinery, structure and organization of the factories are discussed. Conditions of labor as to organizations, and their rules, and wages paid, are given and freely criticized. The methods of manuf. seem to be largely "rule of thumb" and there is room for great improvement by the introduction of rigid methods of control. W. B. JOHNSON.

A study of the Atterberg plasticity method. CHARLES S. KINNISON. *Bur. Standards, Tech. Paper* 46, 18 pp. (1915); cf. *C. A.* 8, 3712.—The practical significance of the Atterberg factor and the rating of clays based on shrinkage or water of plasticity are discussed. The Atterberg factor when used alone is of little significance but when coordinated with the water of plasticity, as recommended in this paper, it appears to be possible to differentiate between the nonsticky or safe working clays and the sticky varieties which are difficult to work. R. S. MCBRIDE.

Report of committee on (wood) preservatives. E. BATEMAN, *et al.* *Proc. Am. Wood Preservers' Assoc.* 1915, 131-40.—The report contains the standard method of analysis of the ZnCl₂ adopted by the association in 1912, specifications for a thermometer for use in creosote oil distn. and definitions of tar and creosote oil. *Zinc chloride analysis:* Weigh 10-14 g. sample into a 600 cc. Jena beaker, add 400 cc. cold H₂O and stir until soln. is complete. Allow basic Zn chloride to settle overnight, filter through a weighed paper (12.5 cm.), collecting the filtrate in a liter graduated flask. Dry the insol. material overnight at 100°, cool and weigh between clipped watch glasses. To each of 3 100 cc. portions of the filtrate add 15 g. NH₄Cl and 5 cc. concd. HCl and dil. to 350 cc. with hot H₂O. Heat nearly to boiling and titrate with K₄Fe(CN)₆, using U acetate as external indicator. If MnCl₂ exceeds 0.3%, modify the method as follows: to the 100 cc. portions of filtrate add 1 cc. H₂O₂ (2.5-3%) and 10 cc. 1:1 NH₄OH. Let stand on steam bath until settled. Filter, wash the beaker and paper twice with hot H₂O, dissolve the ppt. in smallest amt. of 1:1 HCl in original beaker, reppt. as above, filter and wash well with hot H₂O. Add the filtrate to that obtained from the first pptn. To the combined filtrates add 15 cc. HCl, just neutralize with NH₄OH and add 5 cc. HCl Add 25 cc. satd. H₂S soln., dil. to 325 cc., heat to 180° F. and titrate as above. *Estimation of iron and aluminium:* Weigh 10 g. sample into a beaker and dissolve in 100 cc. H₂O. Add dil. HCl to dissolve all basic Zn chloride, add Br-H₂O and boil off excess. Add

dil. Na_2CO_3 until a slight permanent ppt. is formed, add 3 drops glacial HOAc and 2 g. NaOAc and boil. Filter, wash, redissolve the ppt. in the original beakers with hot 1:1 HCl . Reppt. Fe and Al with a slight excess of NH_4OH , filter, wash free from chloride, ignite in Pt and weigh as Fe_2O_3 and Al_2O_3 . To prep. standard $\text{K}_4\text{Fe}(\text{CN})_6$ soln. dissolve 43.25 g. $\text{K}_4\text{Fe}(\text{CN})_6$ and 14 g. cryst. Na_2SO_3 in H_2O and make up to 1 l. Standardize against a known Zn soln. and keep in dark bottles. Prep. the indicator by dissolving 4.4 g. U acetate (free from Na) in 100 cc. hot H_2O and adding 2 cc. glacial HOAc . Wash water should contain 10 g. NH_4Cl and 10 cc. concd. NH_4OH per l. *Standard thermometer*: The thermometer shall be of glass and shall undergo no serious change at the zero point when heated to 400° . The space above the Hg column shall be filled with CO_2 or N . The scale shall read from 0° to 400° in 1° graduations, etched on the stem. The tip of the thermometer shall carry a ring for the purpose of attaching tags. The dimensions are to be: total length 375 mm., tolerance 10 mm., bulb length 14 mm., tolerance 1 mm.; distance from 0 to bottom of bulb 30 mm., tolerance 4 mm.; scale length 295 mm., tolerance 5 mm., diam. of stem 7 mm., tolerance 1 mm.; diam. of bulb 6 mm., tolerance 1 mm. The accuracy of standardization should be: up to 200° to the nearest 0.5° ; 200 – 300° to the nearest 1.0° ; 300 – 360° to the nearest 1.5° . *Tar* is defined as the non-aq., liquid product obtained in the destructive distn. of complex org. matter. Tars are classified as follows: Class A. Tars consisting principally of aromatic compds. and containing well-defined amts. of phenoloids. Class B. Tars consisting principally of aromatic compds., but lacking phenoloids. Class C. Tars consisting principally of aliphatic compds. *Creosote oil* is defined as any and all distillate oils b. 200 – 400° , which are obtained by distn. from tars of Class A. E. H.

U. S., 1,142,989, June 15. H. S. SPACKMAN and E. W. LAZELL. **Hydrated lime plaster** is made by crushing together a mixt. of 85 parts of hydrated high- Ca lime, containing about 5% of unhydrated CaO , 10–15 parts of a fused Ca aluminate mixt. containing a low % of lime and about 12% of NaHSO_4 or KHSO_4 . The crushing reduces the original volume of the mixt. by about 10–15% or more and increases the rapidity of drying and hardening of the mixt.

U. S., 1,143,004, June 15. C. WESTERGARD. **Artificial stone, tiles, etc.,** are made by molding a mixt. of sand 77, cement 21 and S 2% with soapy H_2O , allowing the product to stand in a kiln for 12 hrs. while kept moist by spraying with H_2O to prevent too rapid hardening, then supplying steam to the kiln for 3 hrs. at a temp. of 42° and then raising the temp. to about 100° for 1 hr. The use of soap gives a product of finer texture, more fire-resistant than if H_2O is used alone.

U. S., 1,143,670, June 22. W. WEILER. **Artificial stone.** See Brit., 3,720, 1913 (C. A. 8, 2613).

U. S., 1,144,669, June 29. G. B. SHIPLEY. **Apparatus for treating wood with liquid preservatives.** The wood is placed on a platform within a vertical cylindrical tank and the platform is mounted on a rod raised and lowered by a piston actuated by hydraulic pressure, to raise the platform for loading and unloading and lower it to submerge the wood to the desired depth in the treating liquid. Cf. C. A. 8, 565.

Brit., 4,928, Feb. 25, 1914. T. G. PARK and F. R. HILL. **Processes of mfg. artificial marble.** In one process, colored cementitious fluid is poured into a mass of cementitious material without being mixed, and the combined mass is then poured in a succession of streams on to a polished surface and manipulated to modify the distribution of the color, the product being backed with a thin layer of cement and subjected to pressure. Two or more colored cementitious fluids may be separately poured into the cementitious mass so as to avoid intermingling of the colors. When making pilasters, molding, etc., a smooth, flexible sheet, such as moistened paper, is placed

upon the polished surface to receive the cement, and a woven fabric is applied to the backing before it sets. The complete mass is then removed from the polished surface and the flexible sheet from the molded surface; the plastic mass is then transferred to a mold by means of the woven fabric, and a backing of cement is applied to the molded marble. The figured face may be polished with spirit polish or putty powder (SnO_2). When it is desired to apply the artificial marble to walls, a canvas backing is employed. The product may be secured in position by means of a paste consisting of white lead, gold size, and Parian cement.

Brit., 5,242, Feb. 28, 1914. J. H. AMIES. Cements. See U. S., 1,087,914 (C. A. 8, 1495).

Brit., 5,989, Mar. 9, 1914. E. J. LOVEGROVE, N. G. CROMPTON. Clinker or ash, such as refuse-destroyer clinker, is ground and mixed with 10–20% of a bituminous material to form a paving composition suitable for ramming. Alternatively, clinker ground to an impalpable powder may be employed with a grit composed of sand, stone, or the like, and 10–20% bituminous material added. The clinker may be ground as it leaves the destructor or after it has cooled, and is mixed with the bitumen at a temp. of 275–375° F., the heat for drying, mixing, etc., being supplied by the destructor or otherwise.

Ger., 281,588, Sept. 5, 1912. O. KRANER. In mfg. artificial stone slabs, or the like, from the recovered material of the paper and asbestos manuf., and oxychloride cement, with or without filling, the wet material is mixed with MgCl_2 , the H_2O -content of which is detd. by the amt. of H_2O in the material, and then the oxide is added, as in the manuf. of sorel cement. The wet material consists essentially of kaolin, $\text{Al}_2(\text{SO}_4)_3$, fiber, glue, and other binders.

Ger., 281,694, Oct. 28, 1913. GRUBENHOLZ-IMPRÄGNIERUNG, G. M. B. H. A wood preservative. Those derivs. of the nitrated phenols and naphthols in which the H of the OH is substituted by alkyl or organic acid radical (Ac, HCO, Bz, Me, Et, etc.), have been shown to possess, in general, a higher preservative action than the corresponding nitrophenols or nitronaphthols. Furthermore, the acid derivs. of the nitrophenols (as the Ac deriv.), possess a low m. p., are liquid at the temp. (about 70°) used in impregnation, and form emulsions with H_2O . Consequently, larger amts. can be incorporated in the wood. Finally, the substituted compds. are not explosive, so that the dried wood containing the solid compds. can be used freely in mines, for building, etc. $(\text{NO}_2)_2\text{C}_6\text{H}_4\text{OAc}(a)$ is especially suited for the preservation of wood. It may be produced by boiling $(\text{NO}_2)_2\text{C}_6\text{H}_4\text{OH}(b)$ with 4 times its wt. of Ac_2O and 0.25 times the amt. of fused NaOAc , for a long time under a reflux condenser, pouring the melt into well cooled H_2O , and filtering off the rapidly crystallizing (a) . This compd. is readily sol. in all organic solvents other than ligroin, and is purified by soln. in C_6H_6 and pptg. with ligroin. $(\text{NO}_2)_2\text{C}_6\text{H}_4\text{OOCH}$ is prepd. by melting (b) with 3 times its amt. of anhydrous HCOOH and allowing $1/2$ mol. POCl_3 to drop into the melt gradually. The resulting mass is then heated to about 80° until the evolution of HCl ceases. The reaction product is poured into H_2O and crystallized from indifferent organic solvents such as C_6H_6 . Cf. C. A. 8, 2471.

Ger., 281,793, Oct. 3, 1913. M. RÜPING. Process of preparing wood for impregnation, consisting in forcing needles into the wood and withdrawing them, thereby forming openings which admit the impregnating liquid to the interior of the block.

Ger., 282,368, Jan. 14, 1914. C. FLEISCH. Mfg. a slaked lime of smooth texture and moisture proof, with the aid of beef tallow and a carbohydrate. The CaO is slaked by boiling H_2O and intimately mixed with beef tallow, with the addition of crystd. sugar, while the mass is hot. The sugar increases the hardening properties of the CaO .

tallow mixt. Hot H_2O , of the temp. of the slaking heat of CaO is added, and the tallow is added while the mass is still hot. The sugar is added to restore to the product the hardening properties which are to an extent destroyed by the tallow. When applied and allowed to harden, the surface is porous and resistant to moisture.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Furnace curves. R. J. WEITLANER. *Met. Chem. Eng.* 13, 425-8(1915).—A number of curves are given and their significance discussed. It is concluded that furnaces have individual curves, their fuel consumption being a function of their production in a certain time period. These furnace curves should be used to det. whether fuel has been wasted or saved during a certain working period and to serve for comparing furnaces as well as fuels. A bonus system can be based upon such curves.

F. W. SMYTH.

Note on coal analysis. A. G. STILLWELL. *Chem. Analyst* 13, 9(1915).—For the detn. of volatile matter, the use of 2 Pt crucibles, one inside the other, with a pack of fine asbestos in between them, is suggested.

H. M. LANCASTER.

A new briquetting method for the recovery of high value briquets from a low value brown coal. HERBING. *Feuerungstechnik* 3, 190-1(1915).—H. reviews the present methods of making briquets and states that all previous briquets made of the Austrian brown coal broke up in the fire and no better results were obtained than with the raw coal. The binder used in the new method is a petroleum residue or a cell pitch, the latter being cheaper, particularly in localities where paper is manufactured, although it is lower in heating value. The coal before briquetting is distd. until approx. 3% H_2 , with respect to total combustible matter, is retained in the residue, corresponding approx. to that contained in anthracite coal. About 20% of the volatile constituents is retained in the coal. The by-products of the distn. are recovered and the residue after the addition of 10% of petroleum residue is briquetted. The resulting briquet is similar in its av. comp. to a good bituminous coal. The best results are obtained when the C content of the raw coal on an ash- and moisture-free basis is increased from 75 to 86% in the partially coked coal, and the H_2 content reduced from 5.4 to 3.7%, while the vol. matter is reduced from 47.7 to 21.4%. Analyses are shown of the raw coal, partially coked coal and the finished briquets.

H. R. GUNDLACH.

A new alcohol fuel. ANON. *Chem. Trade J.* 56, 554(1915).—A test of a new fuel known as "Natalite," said to consist of $EtOH$ about 60%, and ether 40%, showed its consumption to be 1 gal. per 26.2 ton miles. The engine started easily either from cold or warm and the valve caps and heads were found to be clean after the trial. A trace of NH_3 is added to correct any tendency towards acidity under running conditions. It is to be manufactured in Natal, South Africa, from waste molasses.

Apparatus for the determination of sulfur in gas. E. R. WEAVER AND J. D. EDWARDS. *Bur. Standards. J. Ind. Eng. Chem.* 7, 620-1(1915).—Combustion method.

ISADOR MILLER.

An investigation on spent oxide residues. ANON. *Gas World* 62, 719-21(1915).—Little information has been published regarding the material arising from the combustion of spent oxide of iron. Attempts have been made to use it in haematite furnaces and for the lining for blast furnaces. Considerable attention has been given to the disposal of this material in purple ore briquettes. With 3% of the burnt oxide added to the purple ore it is possible to secure a briquet of satisfactory mechanical condition and chem. compn. When used for purification purposes the burned spent oxide to be

effective should have a slight alkalinity made by adding slight excess of CaO or NaOH. The red oxide residues scarcely ever show the presence of FeS. The black oxides show an increase of extractable matter by CS₂ and the development of sol. Fe salts on exposure. The quantity of residue resulting from burning spent oxide varies from 16% to 35%, according to the nature of the original purifying agent. Appreciable quantity of CaSO₄ in the oxide decreases efficiency and increases back pressure. Sketches and tables are shown.

M. L. TROWBRIDGE.

The composition of gas in relation to the performance of the Bunsen burner. ROBERT FRENCH PIERCE. *Am. Gas Light J.* 103, 1-5(1915).—The efficiency of gas as a fuel is a function of the flame temp. and the latter quality is not always a function of the calorific value of the gas. The light output of an incandescent mantle was used as an indication of the relative flame temp. of the gases in an incandescent gas lamp. A Welsbach burner was adjusted for max. incandescence, and the horizontal candle-power measured daily from Aug. 3, 1911 to Nov. 21, 1911. The gas was tested daily for calorific value, sp. gr., and candle power. The temp. and humidity of the air in the room were also detd. Carburetted water gas was used. Numerous tables and curves show that the incandescent gas lamp, adjusted at all times for max. incandescence, tends to be essentially a const. consumption, const. light output app., independent of charges of gas, quality, calorific value, sp. gr. etc.

P. J. COLE.

A preheater for use in tar distillation. TAIZO KURODA. *J. Chem. Ind. Japan* 18, 413-7(1915).—A description with a drawing is given of the construction of a preheater in which the tar to be distd. is heated by the hot distillates that come over. It is maintained that this device gives a smoother and more efficient run and a larger yield of light oils than with the ordinary water-cooled app.

H. L. OLIN.

Gasification of tar. A. R. WYATT. *Gas World* 62, 756(1915).—The crude tar is pumped into an overhead tank and flows by gravitation down the coil around the ascension pipe, by which means it is heated by the time it reaches the retort. The tar valve is opened and also the steam at about 80 lbs. pressure, the tar is injected into the retort in the form of spray. The steam is condensed in the usual way, the residue being a dense, hard coke, which may be removed after letting the retort stand for an hour. The rate of flow of the tar is about 40 gals. in 6 hrs. and should produce 2400 to 3000 cu. ft. of 20 candle gas. It is advisable to scatter some fine coke dust upon the retort to facilitate the removal of the residue. The steam keeps the ascension pipe perfectly clear. Sketches explain the operation.

Carbolic acid in Japan. G. H. SCIDMORE. *Commerce Reports* 159, 139(1915).—A plan is under way for starting a semi-official factory for producing carbolic acid from coal tar. Expts. conducted by the Tokyo Gas Co. on the production of benzene, naphthalene, carbolic acid and aniline from coal tar have shown good results.

E. J. C.

Effect of different methods of crushing on the determination of the ash of coke. F. A. EASTAUGH. *Inst. Min. and Met.*, May 20, 1915; *advance proof* 3 pp.; *J. Soc. Chem. Ind.* 34, 602-3.—Four samples of coke were prepd. by different methods. No. 1 was broken by means of a wooden mallet, reduced in size by quartering, then ground in a stone mortar to pass a 60-mesh screen. No. 2 was broken on an Fe plate by means of a steel hammer and reduced to 60-mesh on a bucking plate. No. 3 was broken in the same manner as No. 2, but the final grinding was done in a hand Weatherhead mill. No. 4 was passed through a Taylor crusher, and ground in a Braund disk mill. Two g. were taken from each dried sample and burned, and the amt. of Fe oxide detd. in the

ash. The % of ash found (uncorrected and corrected for Fe_2O_3 , resp.) was: Sample No. 1, 17.79, 17.79; No. 2, 20.78, 17.52; No. 3, 19.58, 17.88; No. 4, 18.25, 17.11. It was assumed that the amt. of Fe found in the ash of No. 1 was a natural constituent of the coke, and the other results were corrected on this basis. No. 4 seems to be the best result, the amt. of foreign matter introduced during the crushing being probably less than in the other 3 samples. E. J. C.

The use of gas coke in central heating plants. H. RIES. Munich. *J. Gasbel.* 58, 198-201, 213-6(1915).—Gas coke and by-product coke were tested in 2 school heating plants. The useful heat was detd. by leading the steam into a surface condenser and measuring the amt. and temp. of the cooling H_2O . All details of tests are given in full. Analyses of the fuels gave for (a) gas coke, (b) by-product coke: total combustible matter, (a) 89.4, (b) 90.0; ash, (a) 7.10, (b) 9.3; H_2O , (a) 3.2, (b) 0.7; calorific value, (a) 12909 B. t. u. per lb.; (b) 12897. The 1st set of expts. were on a cast Fe boiler so arranged that the hot gases were drawn up through the descending column of fuel. The results for gas coke were—load in B. t. u. per sq. ft. heating surface (1), 2480, 2738; useful heat (2), 68.8, 70.0%; loss in heat in stack gases (3), 8.6, 10.2%; loss in stack gases due to incomplete combustion (4), 9.1, 3.8%; loss in unburned residue and ash (5), 3.7, 2.9%. For by-product coke (1), 2434, 2694; (2), 72.6, 74.8; (3), 10.6, 11.0; (4), 4.6, 4.3; (5), 1.1, 0.6. The 2nd set was carried out on a return tubular boiler, and gave for gas coke (4 expts.): (1), 1818 to 3278; (2), 85.0 to 79.6; (3), 8.3 to 12.3; (5), 2.0 to 2.7. For by-product coke: (1), 1825 to 3360; (2), 86.1 to 76.4; (3), 9.5 to 14.5; (5), 0.9 to 1.3. No products of incomplete combustion were found in any test with this boiler. With the higher loads here carried, the trouble from clinker formation was so serious as to make it certain that loads much above 3000 B. t. u. per sq. ft. could not be carried in practice. The conclusion is that there is no choice between the 2 varieties of coke in heating plants. W. L. BADGER.

The use of coke in gas producers. HENRY MARKGRAF. *Stahl u. Eisen* 35, 373-5 (1915).—Producers operated at the Lothring Works, using only coke, furnish a gas which compares very favorably with producers using coal. CARLE R. HAYWARD.

Brit., 5,051, Feb. 26, 1914. E. HOWL and F. PERRY. In the purification of combustible gas, tar fog and finely divided impurities are sep'd. by subjecting the gas to the action of a stream of particles electrostatically charged by means of an influence machine, high-tension dynamo, or induction coil. The gas passes upwards through a tower of conducting material, at the top of which is an insulated water-tank connected to a dynamo, etc. Fine spray escapes through jets and the tar or other particles coalesce and collect in the sump.

Brit., 5,142, Feb. 27, 1914. D. D. BARNUM, H. A. CARPENTER and RITER-CONLEY MFG. CO. Gas retorts are arranged in vertical rows, and the retorts of each row, or the retorts of pairs of adjacent rows, have, extending from the mouthpieces, sep., valve-controlled connections with a vertical off-take pipe leading to a main located either at the top or bottom of the retort bench. Where a sep. off-take pipe is provided for each vertical row of retorts, the pipes may be arranged in pairs between pairs of rows of retorts, and the pair of pipes may be replaced by a single conduit with a central dividing partition. Cf. *C. A.* 8, 2938.

Brit., 5,730, Mar. 6, 1914. H. STRACHE. A mixture of distillation and water gas is obtained in an app. comprising a fuel bed and retort, through which coal passes to the fuel bed. During the hot blast, air is admitted by a pipe, the CO produced is burned with air supplied by a pipe, and the combustion gases, after heating the retort, escape by another pipe. Distn. gas collects in a space above the retort, and during the run when steam is admitted, the distn. gases are displaced into the gas-outlet pipe which is kept open during the following hot blast until the mixt. of H_2O and distn. gas still in the retort is displaced by the combustion gases.

Brit., 5,734, Mar. 6, 1914. R. PEARSON and CHALK FUEL POWER GAS & BY-PRODUCTS CORPORATION. Gas, lime, and other by-products are obtained in a producer by feeding on to a bed of incandescent fuel briquets containing chalk, solidified tar, naphtha oil, and small coal or peat, or both, the mixt. being subjected to steam in the prepn.

Brit., 5,764, Mar. 6, 1914. D. KOECHLIN. Purifying coal gas and increasing its CH_4 content by passage of the gases evolved in the latter stages of the distn. of coal, first over Fe_2O_3 heated to 120° , and then over Ni heated to 300° ; water-gas may be added to the gases treated. The Fe_2O_3 and Ni are arranged in 2 chambers which are heated by flue gases from the ovens or by generator gas, the heating gases first heating the Ni and then the Fe_2O_3 . The Ni can be regenerated continuously by mixing a small proportion of air with the gas. The Fe_2O_3 is obtained by calcining pptd. $Fe(OH)_3$ and the Ni by reduction of its oxide. The enriched gas is finally mixed with the gas obtained by passing the gases of the 1st stage of distn. through a red-hot chamber.

The generator is formed of several similarly constructed sections with elec. granular C resistance heaters which pass through the sections horizontally. The walls of the sections are formed of an outer metal shell, an intermediate insulating layer, *e. g.*, asbestos, and an inner refractory brick lining. The elec. heaters are enclosed in a mixt. of SiO_2 , $CaCO_3$ and Na silicate.

U. S., 1,144,801, June 29. B. VAN STEENBERGH. Electric resistance heater for hydrocarbon generators such as that of pat. 1,144,800 (*supra*). A resistance packing of granular C is placed in a metal tube lined with cardboard and coated with a mixt. formed of SiO_2 , $CaCO_3$ and Na silicate.

Brit., 5,434, Mar. 3, 1914. C. WHITE. In a process of cracking oils, etc., mineral oils and residues are brought in a liquid state and without addition of steam or H_2O on to CaO , or CaO containing C, heated to a temp. of 400–650°. The operation is conducted under reduced pressure in order to prevent the formation of gas. The vapors are condensed and fractionated for the production of petrol, the remaining heavy oils being subjected to a further cracking. The CaO may be regenerated by removing the deposit of C by heating it in a current of air.

Brit., 5,847, Mar. 7, 1914. O. H. VALPY and O. D. LUCAS. Catalytic bodies are prepd. by heating to reduction and sintering a mixt. comprizing a metal oxide, and a metal compd. of the organic type composed of metal C, and O with or without H and which, when heated, evolves CO or CO_2 . If it is desired to complete the reduction to the metallic state, a reducing agent which is solid or becomes so on heating is added. Suitable organic compds. are carbonates, oxalates, tartrates or acetates, and in examples the following mixts. are used: Ni and Fe oxalates and oxides, and C; red oxide of Fe, $MnCO_3$, $Fe(OCO)_3$, C and Al; Fe_2O_3 and NiO , Fe tartrate and Ni acetate and Al. The C and Al act as the reducing agent, and it is found that the production of the material is facilitated by the addition of Al, Ce, Mg, or other alk. earth metals. The mixt. is briquetted with the aid of a suitable binding material such as tar, which may form all or part of the reducing agent. The catalysts produced according to the above examples are suitable for use in cracking hydrocarbon oils. Cf. *C. A.* 9, 711.

A. D. LITTLE.

The [British] Empire's resources in paper-making materials. S. C. PHILLIPS. *J. Roy. Soc. Arts* 63, 613–36(1915).—A very thorough paper on the subject, followed by an interesting discussion. E. J. C.

Arsenic content of modern wall-papers. A. F. SCHULZ. *Arb. kais. Gesundh.* 48, 303–20(1915).—Of 311 samples of com. wall-paper examd. 80% were found to contain As. Quant. exam. showed that the As was present in such quantity as might be ascribed to the unavoidable impurities present in the colors employed in the manuf.

The small amts. of As found cannot be considered harmful from a hygienic standpoint. Whenever it is desirable to det. whether a wall paper may or may not be injurious to health the As present must be detd. quant. The manner in which As poisoning is brought about through wall papers has not been satisfactorily established, but it appears that the As-containing dust present in the air of the room is responsible for it. There is a lack of evidence to show that As poisoning as a result of wall papers has taken place of late, and the proofs in the cases described are not sufficient to warrant such an assumption.

C. A. NOWAK.

Equivalent weights per ream. SINDALL AND BACON. *Paper Makers' Monthly J.* 53, 146-7 (1915).—The authors review briefly 6 different methods used at present for detg. the equiv. wts. per ream, and suggest the use of a definite relation between unit area and unit weight.

Sulfite waste liquors and their utilization. W. KIBY. *Chem. Ztg.* 39, 212-4, 261-3, 284-5, 307-8, 349-52 (1915).—A general discussion. J. H. MOORE.

Explosions of paper dust 24.

U. S., 1,141,510, June 1. R. WILLSTÄTTER. Dissolving cellulose. See Ger., 273,800 (C. A. 8, 2948).

U. S., 1,141,951, June 8. A. A. DUNHAM. Mixture for coating paper for lithographers use, etc., formed of hydrolyzed starch (neutralized with NH_4OH) 25, casein 2.5, Na_2HPO_4 0.4, kaolin or other mineral filler 100 and H_2O 150 parts.

U. S., 1,142,922, June 15. M. C. WHITAKER and J. S. BATES. Separating fiber and other constituents of resinous wood by treating chips with a dil. NaOH soln. at the boiling point under 20 lbs. pressure per sq. in. and then adding NaOH to the resulting soln. to bring the total NaOH present to about 6% and to cause sepn. of resin soap. During the boiling under pressure the turpentine vapors are led off and condensed.

U. S., 1,143,401, June 15. J. L. JARDINE. Obtaining paper pulp or fiber from bamboo. See Can., 160,045 (C. A. 9, 1246).

U. S., 1,143,587, June 15. M. W. MARSDEN. Recovering fiber from waste portions of the cotton plant by comminuting and mechanically sepg. the light and heavy portions by a blower or "cyclone separator," treating with H_2O and steam under pressure to ext. the sugar, tannin, coloring matter, etc. and then treating with an alk. soln. under high pressure to remove incrusting substances. Paper formed from the fiber possesses great strength and uniformity.

U. S., 1,143,979, June 22. W. G. LINDSAY. Solvent for acetylcellulose (such as is also freely sol. in acetone) formed of EtOAc 60-70 and MeOH 30-40 parts. Cf. C. A. 9, 1546.

Fr., addition 18,345, Oct. 21, 1913, to 417,274. BAYER & Co. Mfg. cellulose esters. Not only acid sulfates of the primary aromatic amines, but also neutral sulfates thereof (e. g., *o*-toluidine sulfate) and of the other amines (methylamine), serve to effect the production, in the acetylation process, of acetone-sol. products.

Fr., 468,380, Apr. 22, 1913. P. JOLIOT. In mfg. lustrous cellulose threads, the stretched yarns are converted into alkali-cellulose by means of NaOH, and then subjected, while stretched, to the mild action of CuO-NH_3 or CS_2 , whereupon the regeneration of the cellulose follows in the known manner.

Ger., 281,225, Nov. 29, 1913. BADISCHE. The acyl compds. of completely hydrogenated aromatic amines, which are readily accessible technically, serve very well for the manuf. of celluloid-like masses. They possess an exceptional softening and solvent power for nitrocellulose and the like, and the products obtained with their

use are odorless and colorless, and stable to heat and air. They possess, also, uniformly, a low sp. gr. *E. g.*, 35 parts of acetyldicyclohexylamine (obtained by acetylizing dicyclohexylamine, and forming colorless crystals *m.* 103°) are mixed with 100 parts of nitrocellulose, with the addition of alc., and worked in the usual manner. The product is a beautiful, colorless, celluloid-like mass.

Ger., 281,374, Nov. 24, 1911. Addition to 256,922 (*C. A.* 7, 2116). BAYER & Co. In the manuf. of liquid solutions of acetyl celluloses, alc. solns. of ZnCl_2 or thiocyanates need not be employed, as specified in the principal patent. Aq. solns. of the metal salts mentioned, as well as of other metal salts, dissolve acetylcellulose much more readily, if such solns. are concd. *E. g.*, 5 parts acetylcellulose may be dissolved in a soln. of 70 parts ZnCl_2 and 40 parts H_2O . Additions, such as 5 parts of triacetin, or dyes, as 2 parts diamond black, may be made to the resulting clear soln. Or 5 parts of acetylcellulose are dissolved in a soln. of 70 parts SnCl_4 and 30 parts H_2O , a clear soln. being obtained. Also 80 parts SbCl_3 and 20 parts H_2O make a good soln. with 5 parts acetylcellulose. The resulting clear solns. can be dild. with the corresponding metal salt solns. or even with alc. or other solvents, within wide limits, and permit of ready filtration (as by filter press) and purification. The solns. are physiologically indifferent, so that the operators are not injured. By dild. with H_2O or other pptnt., the acetylcellulose seps. out at once in the form of a gelatinous or flocculent mass. Cf. *C. A.* 8, 2060.

Ger., 281,515, Feb. 2, 1913. W. SCHACHT. In the manuf. of sizing for paper, the completely cooked resin soap, with added colloidal substances, is acted upon by liquid or gaseous acids or acid salts, preferably with the simultaneous introduction of a current of air, whereby the material is more or less decomposed. As colloidal substances are specified starch, casein, animal glue, saponified or unsaponified oils or fats, vegetable protein, water-glass and the like. As gaseous acids are used SO_2 and CO_2 , and as acid salts are specified bisulfates, bisulfites, and bicarbonates of the alkalis. The colloidal resin size must be rendered alk. separately, and then added to the other ingredients in the mixing cylinder. A complete sizing effects a saving of resin and alum or $\text{Al}_2(\text{SO}_4)_3$.

Ger., 282,050, June 14, 1913. C. G. SCHWALBE. Disintegration of wood and similar vegetable fiber for the manuf. of cellulose, with the use of Ca sulfite lyes (satn. hot or cold), followed by steaming to remove the soln. *E. g.*, the comminuted wood is soaked for 3-5 hrs., at 70-100°, with one of the ordinary Ca sulfite solns. of about 3% by wt. of SO_2 , the liquid is drawn off, and gaseous SO_2 is added until the acid contained in the wood is doubled. The lye still present is then removed, and the material is steamed.

Ital., 129,729, Feb. 27, 1913. C. BENIAMINO. Process of mfg. wood pulp, consisting in heating the wood by means of steam (without pressure) and then exhausting the vat. After having absorbed a solvent (basic salts) it is cut up into fine fibers.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Permissible explosion-proof electric motors for mines; conditions and requirements for test and approval. H. H. CLARK. U. S. Bur. Mines, *Tech. Paper* 101, 14 pp. R. S. MCBRIDE.

Explosions of paper dust and how they may be prevented. ANON. *La sicurezza e l'igieno nell'industria* 1914, 186; *Ind. chim. min. met.* 2, 83-4 (1915).—In the paper

works of Jules Petit, Turcoing, in which are manufd. paper tubes to cover the spindles of cotton spinning machines, the edges of the paper must be smoothed off before pasting; this is done in special machines, called "gratteuses," and in this operation is formed a dense powder which is drawn by a ventilator into a chamber and collected on jute filters; at the end of the week, workmen enter the dark chamber and empty the contents of the filters into bags. On one such occasion, the workmen being provided with lanterns with good glass globes, there was a most violent explosion and the whole chamber became a furnace. Analysis of the dry dust showed that it contained 17.55% ash and 82.65% org. matter, with a mean moisture content of 4.50%. Inflammability tests showed that a cloud of the dust blown over the igniter gave a flame 17 cm. long per g. dust. The only safe lights to use in the presence of such dusts are incandescent elec. bulbs.

C. A. ROULLER.

Battery-bell signaling system (WHEELER) 4.

U. S., 1,143,330, June 15. C. M. STINE. Dynamite is made with the addition of nitrated ivory nut to the usual constituents of dynamites. The proportions may be: nitroglycerin 35, nitrated cotton 1, nitrated ivory nut 5, NaNO_3 52 and wood meal 7 parts. The nitrated ivory nut is insol. in nitroglycerin and its use as a substitute for an equal amt. of nitrated cotton produces an explosive which is more easily detonated.

U. S., 1,143,623, June 22. W. M. GROSVENOR. Preventing explosions of vapors of ether, benzene, etc., given off in drying celluloid or other materials. The drying is carried out in 2 separate stages in different compartments. During the first stage, the % of inflammable vapor in the compartment is kept so high as to form a non-explosive mixt. and during the second stage the % is kept so low as also to prevent formation of an explosive mixt.

U. S., 1,144,076, June 22. H. STAIGER. Composition for match heads composed of KClO_3 , sulfide of P and other usual ingredients of match heads with a binder of "feculose."

U. S., 1,144,077, June 22. H. STAIGER. Match-head composition composed of usual ignitable ingredients including KClO_3 and sulfide of P united with a binder of glue 70% and gum ammoniac 30% with sufficient H_2O to form a pasty mixt. Cf. C. A. 8, 1872.

Brit., 5,736, Mar. 6, 1914. H. STOLTZENBERG. The use, as explosives or ingredients of explosives, of compds. of betaine with acids rich in O such as HNO_3 , HClO_3 , HClO_4 , H_2CrO_4 , picric acid, and $\text{H}_2\text{Mn}_2\text{O}_8$. One example contains 25% nitroglycerin, 30% betaine nitrate, 38.5% wheat flour, and 0.5% betaine. The following compds. of betaine are described: Two with HNO_3 —one $\text{Bet.}_2\text{N}_2\text{O}_5$ obtained as white crystals by passing N_2O_5 into an ice-cooled soln. of betaine in MeOH, and another $\text{Bet.}_2\text{N}_2\text{O}_5$ obtained by the action of HNO_3 on betaine for a long time under pressure; $\text{Bet.}_2\text{HNO}_3$ obtained as white, lustrous plates by evapg. betaine down with HNO_3 or by repeatedly evapg. the hydrochloride with conc. HNO_3 in excess; $\text{Bet.}_2\text{H}_2\text{Cr}_2\text{O}_7$ crystallized by evapg. betaine down with H_2CrO_4 in aq. soln.; $\text{Bet.}_2\text{HClO}_3$, white crystals from betaine and HClO_3 ; and $\text{Bet.}_2\text{HMnO}_4$ from betaine and $\text{H}_2\text{Mn}_2\text{O}_8$.

Brit., 5,737, Mar. 6, 1914. H. STOLTZENBERG. The use, for stabilizing nitro explosives, of betaine and compds. of betaine with acids rich in O and with salts, such as HNO_3 , H_2CrO_4 , HClO_3 , NaBr , and BaI_2 . One example of explosives so stabilized contains 25% nitroglycerin, 36% betaine nitrate, 38.5% wheat flour, and 0.5% betaine.

Fr., addition 18,487, Oct. 17, 1913, to 410,239. C. CLAESSENS. In mfg. smokeless powder, the nitro derivs. of benzene, toluene, phenol, naphthalene, di- or tri-

nitrotoluene (20-30%), used instead of nitroglycerin for gelatinizing nitrocellulose, can be employed with the use of volatile solvents.

Ger., 280,820, Jan. 8, 1913. W. KRAUSHAAR. Electric miners' lamp for the automatic detection of fire-damp or other combustible gas. In circuit with the lamp is arranged a wire heated by catalytic combustion of definite cross-section and length, of an especially high positive or negative temp. coefficient such as Fe or B, so that simply by the temp. change caused by the presence of the gas mixt. sought to be detected, a change in the resistance of the lamp circuit results sufficient to cause an appreciable change in illumination.

Ger., 280,962, Oct. 3, 1912. H. SCHÜRMANN. Device for preventing the propagation and action of coal-dust and fire-damp explosions.

Ger., 281,157, May 22, 1913. BADISCHE. Quantitative gas analysis by the acoustic method, whereby the gas mixt. under exam. is set in vibration, and the resulting tone is compared with a tone of definite pitch. The resulting waves are transmitted telephonically or microphonically to a set of reeds which correspond to certain wave numbers. The set of reeds may be selected with reference to a few detd. % constitutions of the gas mixt. The reeds, when caused to vibrate, actuate a registering or alarm device. E. g., the presence of CH_4 (0-10%) in air may be detected with the aid of a tone of 980 vibrations per sec. The analysis-pipe is made to vibrate with air with a frequency of 1000 per sec., so that with 0% CH_4 there are 20 waves, 22 waves in the presence of 1% CH_4 , and 43 waves in the presence of 10% CH_4 .

Ger., 281,906, Oct. 21, 1913. CENTRALSTELLE FÜR WISSENSCHAFTLICH-TECHNISCHE UNTERSUCHUNGEN, G. M. B. H. Mfg. hexanitroethane by subjecting the solns. of $\text{C}_2\text{H}_5(\text{NO}_2)_4$ obtained by treating its salts in concd. acids (e. g., 100 g. of the K salt in 500 cc. concd. H_2SO_4 of sp. gr. 1.84), to the action of nitrating agents (e. g., 30 cc. of a mixed acid of equal parts by vol. of H_2SO_4 of sp. gr. 1.84, and HNO_3 1.52), at about $+10^\circ$. The $\text{C}_2(\text{NO}_2)_6$, m. 141° , can be used as an explosive.

Ital., 132,194, Apr. 24, 1913. SOC. ANON. "LA SABULITE." Increasing the power of explosives by the addition of alk. earth silicides. NH_4NO_3 is also added if the explosive is fresh.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Revival of the use of natural dyestuffs. E. S. CHAPIN. *J. Ind. Eng. Chem.* 7, 625-8(1915).—An address before the National Assoc. Cotton Manufacturers. Methods and recipes are given.

ISADOR MILLER.

British national dye scheme. D. G. ANDERSON. *J. Ind. Eng. Chem.* 7, 538-41 (1915).

ISADOR MILLER.

Turkey red oils from fatty acids. F. CERBAN. *Seifenfabr.* 35, 477-9(1915).—Castor oil fatty acids were prepd. from the oil in the usual manner. A low degree of sulfonation was obtained at a temp. of 30 to 35° by mixing 101 g. of the fatty acids with 15 g. of 66° Bé. H_2SO_4 and allowing to stand for 2 days with stirring, after which 161 cc. of 10% NaOH were added. The oil remained clear. A moderate degree of sulfonation was effected under the same conditions, using 25 g. of 66° Bé. acid. After standing 20 hrs. 100 cc. cold H_2O were stirred in and then 100 cc. hot H_2O , so that the temp. of the mixt. was 45° ; after one day the acid H_2O was drained off and the H_2SO_4 detd. The amt. taken up by the oil was 6.1 g. After neutralization the oil was dild. till it contained 50% fatty acids. It remained unaltered for several months. A high degree of sulfonation was produced by using 35 g. of acid with the same amt. of

oil as above. The sulfonated oil contained 11.8 g. of H_2SO_4 and was somewhat darker than the moderately sulfonated.

E. SCHERUBEL.

Cottonseed crushed and linters obtained 27.

U. S., 1,143,543, June 15. J. L. JARDINE. Preparing jute and similar textile materials for bleaching by treating each 24 oz. of the material with 1 gal. of a soln. of $\text{Mg}(\text{HSO}_3)_2$ containing 1.4% combined SO_2 and 2.1% free SO_2 at about 143° for 20 hrs. while allowing sufficient escape of SO_2 to prevent rise of pressure and adding H_2O as required during the heating to compensate for that lost by escape of steam.

U. S., 1,143,569, June 15. B. BORZYKOWSKI. Viscose threads are "set" by treatment with a soln. formed from *p*-nitrosodimethylaniline or similar nitroso compd. 0.5, $(\text{NH}_4)_2\text{SO}_4$ 10, NaCl 15 and H_2O 100 parts. The nitroso compd. prevents liberation of free S by decompn. and a stable product of great luster and transparency is obtained.

U. S., 1,144,181, June 22. A. ERLNBACH and K. MARX. Dyes for furs, hair, etc., are formed by mixing *p*-aminodimethyl- (or diethyl) aniline sulfate or hydrochloride with *m*-diaminoanisole or *m*-diaminophenetole sulfate or hydrochloride. The mixt. dyes deep blue-black from an aq. soln. with NH_4OH and H_2O_2 .

U. S., 1,144,325, June 22. A. ERLNBACH. A dye for hair, furs, etc., is made from sulfates of $(\text{NH}_4)_2\text{C}_6\text{H}_4\text{Me}$ and $(\text{NH}_4)_2\text{C}_6\text{H}_4\text{OMe}$ in the proportions of 2:1. The product is sol. in H_2O and when oxidized with H_2O_2 gives a full bluish black on furs or hair previously mordanted with FeSO_4 .

U. S., 1,144,577, June 29. E. WRAY and F. HESS. Dark blue or black vat dyes are made by condensing α -isatin derivs. with derivs. of aminonaphthols; e. g., 2-benzoylamino-5-hydroxynaphthalene with isatin- α -anilide, 5-hydroxy-1-phenylnaphthylamine with 5-chloroisatin-2-*p*-chloroanilide or 5-hydroxy- μ -phenyl-1,2-naphthimidazole with isatin- α -chloride.

U. S., 1,144,655, June 29. G. HEBERLEIN. Producing pattern effects on mercerized cotton fabrics. See Ger., 280,134 (C. A. 9, 1396).

Brit., 5,011, Feb. 26, 1914. FARBW. V. M. L. & B. Printing fabrics with reduction dyes, such as vat or S dyes, by lithographic or typographic processes, by applying the dye, finely ground, with a varnish or oxidizable oil to the fabric, which has been prepd. with an alk. reducing agent, and fixing by steaming. In a modification, the alk. reducing agent is applied to the fabric after the color has been printed on. A mixt. of helindone violet R and printers' varnish is specified as the color, and a mixt. of hydrosulfite NF, Na_2CO_3 , wheat starch, and H_2O , as the alk. reducing agent.

Brit., 5,238, Feb. 28, 1914. F. STEINIG. Threads, films, etc., are manufd. from viscose by squirting into a warm and highly concd. soln. of a neutral salt, to which a small % of a sol. NH_4 salt has been added, and allowing the thread so formed to rest in the air to regenerate the cellulose. The bath referred to consists of a soln. of Na and NH_4 sulfates, and is employed at a temp. of 30 – 40° . Cf. C. A. 8, 3373.

Brit., 5,569, Mar. 5, 1914. A. R. WHITEHEAD and J. FARRAR. Constructional details of a dyeing machine.

Fr., 467,887, Jan. 30, 1914. E. T. J. WATREMEZ. Bleaching vegetable fibers. See U. S., 1,133,769 (C. A. 9, 1395).

Fr., 468,821, Feb. 23, 1914. HEBERLEIN & Co. In the manuf. of a wool-like cotton fabric, 51° Bé. H_2SO_4 (and stronger) exerts upon the cellulose a gelatinizing and parchmentizing action, whereby the cellulose is weakened, while acid of a strength below 51° Bé. is almost without action within 15 mins. If the cellulose (cotton)

were previously mercerized and therefore fast to acid, the luster is destroyed by acid of 49–51° Bé. (49.5–50.5° Bé.), the parchmentizing effect is not produced, and the fabric is softer, denser, and more like wool. The same effect is produced by compression. The period of action is several secs. to several mins. H_3PO_4 of 55–57° Bé., HCl of 1.19, HNO_3 of 43–46° Bé., ZnCl_2 of 66° Bé. at 60–70°, and a short period of action of CuO-NH_3 produce the same effect.

Ger., 280,710, May 10, 1913; addition 18,674, Dec. 20, 1913, to Fr., 451,798. BADISCHE. New derivs. of dibenzanthrone and vat dyes derived therefrom. The green vat dyes formed according to the principal process of Fr., 451,798, may be converted, by treatment with Br, into new vat dyes having more desirable properties, and showing greater resistance to b. soap- and soda-water.

Ger., 281,571, Nov. 5, 1911. Addition to 258,638 (C. A. 7, 3546). LANDAU & Co. and I. KREIDL. Of the salts of the rare earths used according to the principal patent for weighting silk, only those are applicable which, in the hydrated form, do not oxidize in the air, since the silk suffers by the oxidation process. By admixt. with such salts of the rare earths as do not possess these disadvantages, Ce salts can be rendered suitable for weighting silk. In the waste product from incandescent mantle manuf., Ce is sepd. until the mixed material, in the hydrated form, does not oxidize in the air.

Ger., 281,581, Dec. 23, 1910. W. MATHESIUS and M. FREIBERGER. In bleaching cotton goods, the material, bucked in the usual manner, is immersed in a heated alk. ice bath, preferably in a continuous operation. The Cl-content of the material after treatment is reduced to $\frac{1}{16}$ by rinsing with a more dil. Cl liquor. The material is then passed through a similar app. in which an acid Cl soln. is allowed to act. The material is then washed in the usual manner. The baths are heated to facilitate the bleaching action. In order that the Cl baths shall not be heated too strongly, a heating agent is employed whose temp. is but slightly above that of the desired temp. of the Cl baths (e. g., warm H_2O). In this process the alk. Cl bleaching process need not be carried to the formation of oxycellulose.

Ger., 281,797, Oct. 23, 1912. H. EICHELER. Perforated yarn spool of metal, for dyeing, spinning, and weaving purposes.

Ger., 281,911, Aug. 13, 1913. BAYER & Co. Mfg. sulfonyl chlorides of the anthracene series. Anthraquinone or β -chloroanthraquinone are converted, by the action of chlorosulfonic acid, into the chlorides of the dichloroanthracenedisulfonic acids.

Ital., 129,734, Feb. 27, 1913. A. BARDELLI. In a process of mfg. artificial silk from com. mercerized cotton, the decompn. of the collodion during the treatment at ordinary temp. is prevented by rendering the Schweitzer reagent alk. with NaOH before bringing it into contact with the mercerized cotton.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

North Dakota paint and oil laws. ANON. *Drugs, Oils and Paints* 31, 17–8 (1915).—Copy of law regarding the sale of boiled linseed oil and the adulteration of paints. Linseed oil must comply with the U. S. Pharmacopeia tests for purity and boiled linseed oil must be heated to 225° F. All white lead or compds. intended for use as a substitute thereof must be labeled to clearly show the % of each mineral constituent. All mixed paints must show their true compn. unless made of pure linseed oil, lead carbonate, oxide of Zn, turpentine, Japan driers and pure colors. The presence of

rosin spirits, C_6H_6 , benzine, or other than spirits of turpentine or turpentine driers shall be clearly shown on the label with the % thereof. The presence of not more than 1.5% of H_2O will not be considered as adulteration. Western Zn oxides carrying not more than 5% of $PbSO_4$ will be considered as commercial ZnO. The term "white lead" may be used only for the basic carbonate. Substitutes for linseed oil must be shown on the label.

E. W. BOUGHTON.

Prohibition of lead paints in Great Britain. ANON. *Oil, Paint and Drug Rep.* 87, No. 22, 18(1915); cf. *C. A.* 9, 1999.—This article includes a report of the expert testimony before the govt. committee, and a minority report which urges a trial of regulation before prohibiting the use of lead paints. Also in *Drugs, Oils and Paints* 31, 57-60(1915).

E. W. BOUGHTON.

Determination of moisture in shellac. A. C. LANGMUIR, *et al.* *J. Ind. Eng. Chem.* 7, 633(1915).—Official method worked out by a committee of the Am. Chem. Soc. and approved by several manufacturing companies.

ISADOR MILLER.

The condensation products of phenol and formaldehyde with special reference to bakelite. GORO MATSUMOTO. *J. Chem. Ind. Japan* 18, 434-80(1915).—M. classifies the various condensation products of $PhOH$ and CH_2O in 3 groups, *viz.*, crystallizable, sol. and fusible, insoluble and infusible. He sums up the results of his investigations on bakelite as follows: (1) the whole process may be divided into 3 stages: the initial condensation, the concn. of the products, and the hardening. Reactions in all stages are accelerated by certain reagents: (2) CH_2O which combines with phenol in the initial stages may be well estd. by Lemme's method. (3) The following may be used as condensing agents: H_2SO_4 , HCl , NH_4OH , $(CH_3)_4N_4PhNH_2$, Na_2SO_3 , Na_2CO_3 and $NaOH$. Neutral salts have no effect. (4) As a hardening agent only basic substances as $NaOH$ or NH_4OH can be used, of which the latter is the better. (5) The combination of $NaOH$ as the condensing agent and NH_4OH as the hardener gives the best results both in yield and quality. (6) With the use of cresol instead of phenol an analogous substance is obtained.

H. L. OLIN.

Bakelite suit decision. ANON. *Met. Chem. Eng.* 13, 411-4(1915).—A full review of the decision in favor of the plaintiff in the case of the General Bakelite Co. *versus* the Geo. J. Nikolas & Co. varnish and lacquer manufacturers. The case is not only of com. importance, but very instructive in various of its legal and chemical aspects. The bakelite patents in question were held valid and infringed.

F. W. SMITHER.

Constituents of the fruit of the Osage orange (MCHARGUE) 12.

U. S., 1,143,110, June 15. C. ELLIS. Composition for removing paint and varnish, composed of denatured alc. 40, $MeEtCO$ 25, propionic acid 6 and ceresin wax 0.25 parts; or acetone 30, C_6H_6 25, propionic acid 4 and ceresin wax 1 part. Kerosene, toluene, CCl_4 , C_6H_5Cl , amyl acetate, starch, etc., may also be added. Cf. *C. A.* 9, 1849.

U. S., 1,143,111, June 15. C. ELLIS. Paint- and varnish-remover formed of acetone 30, C_6H_6 25, butyric acid 4 and ceresin wax 1 part. This mixt. is suitable for spreading on the surface under treatment; for dipping articles in the remover, the latter is formed of denatured alc. 40, $MeEtCO$ 25, butyric acid 6 and ceresin wax 0.25 parts.

U. S., 1,143,130, June 15. A. E. NIENSTADT. Composition for removing paint and varnish, composed of $MeOH$ 7.5, acetone 7.5, C_6H_6 15, castor oil 2, NH_4OH ($26^\circ Be.$) 2, $C_{10}H_8$ 4 and NH_4 stearate 8 parts.

U. S., 1,143,387, June 15. L. HAMBROCK, JR. Composition for removing paint or varnish, formed of copal 6, tung oil (polymerized by heat) 4, beeswax or ceresin

wax 4 and oil from the distn. of copal 8 parts. This forms a pasty mixt. which may be diluted with C_6H_6 or MeOH.

U. S., 1,143,714, June 22. O. W. KNIGHT. A plastic phenol resin mixture (suited for making varnish or insulation) is formed by fermenting waste sulfite liquor, adding $Na_2Cr_2O_7$ or $K_2Cr_2O_7$ to convert into aldehyde at least part of the alc. produced, mixing with phenol and heating to effect condensation. $FeCl_3$, $FeSO_4$ and $Fe_2(SO_4)_3$ may be used as condensing agents and by omitting the dichromate the alc. may be distd. off and recovered during the condensation.

U. S., 1,143,877, June 22. W. ALEXANDER. Composition for removing paint, formed of a 50% aq. soln. of glucose 4, pyroxylin varnish 57, acetone 10, C_6H_6 17, H_2O 10 and a C_6H_6 soln. of paraffin 0.1 part.

U. S., 1,143,878, June 22. W. ALEXANDER. Composition for removing oil- or water-paints, formed of a 50% aq. soln. of glucose 10, a 10% acetone soln. of nitro-cellulose 70, C_6H_6 20 and H_2O 15 parts.

U. S., 1,144,599, June 29. H. JAMSON. Paint which will withstand repeated washing, is made from linseed oil 1 pint, powdered size 8 oz., turpentine 8 oz., Paris white 10 lbs., "patent" drier 8 oz., a pigment such as Zn white or red or white Pb 2.5 lbs. and H_2O 2 qts.

U. S., 1,144,701, June 29. C. ELLIS.

Apparatus for making white lead. Molten Pb from the receptacle 1 is atomized with air and steam and the fine solid Pb formed is passed through the tube 8 by a screw conveyor. Air, steam and CO_2 are brought into contact with the finely divided Pb in the tube 8 and the hydrated material then passes through the tube 17 where it is treated with CO_2 . Cf. C. A. 9, 2000.

Brit., 5,432, Mar. 3, 1914. G. CUNEO. Anti-fouling coating compositions for ships, etc., contain inorganic compds. of F derived from HF or H_2SiF_6 as the anti-fouling ingredients. These ingredients may be added also to ordinary paints to increase the hardness of the coating. An example of a comp. for coating submerged structures comprizes 50% of varnish consisting of resin and benzene, 25% of F compd., and 25% of pigment such as ZnO or Fe_2O_3 .

Ger., 280,074, Mar. 3, 1914. E. ROLFFS. Process of transferring pigment pictures on rolls, especially for polychrome printing.

Ger., 281,452, Feb. 28, 1913. Addition to 272,465 (C. A. 8, 2628). E. F. WERNIG. In the manuf. of a linseed-oil-varnish substitute from animal oils, such as train and the like, the process of the principal patent is modified in that the oil is at first heated to a moderately high temp. and then, without further application of heat, but with prevention, as much as possible, of radiation, it is allowed to stand for some time.

The splitting up of the readily hydrolyzed glycerides proceeds then with comparative rapidity. Furthermore, during this period, small amts. of fatty acids, hydrocarbons, traces of glycerol and acrolein distil over. In these interposed periods of rest, in which the application of external energy is suspended, considerable time is saved. A white fat is obtained as the product of distn. The period of treatment

for the distn. is shortened to about 6 hrs. *E. g.*, fish oil is heated first in the still at about 280° . The fire is then removed, and the draughts closed for 1–2 hrs. In this period a spontaneous heating of the oil to about 350° takes place, and small amts. of fatty acids, hydrocarbons, and traces of glycerol and acrolein, together with some H_2O , distil over. During the breaking down of the glycerides incident to this action, the temp. gradually falls. At a temp. of $260\text{--}85^{\circ}$ the distn. with steam (of about 375°) is begun, with or without vacuum, in order to shorten the operation as much as possible. The final product is an almost white distillate. A thick oil or varnish substitute equally as valuable as the product of the principal patent is obtained. Cf. *C. A.* 8, 3128; 9, 726.

Ger., 281,483, Aug. 12, 1913. A. EIBNER. Light and dark cinnabar. See U. S., 1,137,467 (*C. A.* 9, 1696).

Ger., 281,504, May 29, 1913. C. G. BÖSSENROTH. Mfg. paste tempera colors in tubes or boxes. The ordinary oil colors as well as the tempera colors turn dark in time (brown) because of the high oil content. The products of this process contain no fats or oils, are insol. in H_2O after drying, and are unaffected by atm. influences. They are obtained by working pigments up to an emulsion with binder consisting of gelatin soln. and blood fibrin, and then adding $HCHO$ or other hardener for the binder. So long as these colors remain away from the air no change takes place in the paste and its spreading property. After application and drying the coatings cannot be wiped or washed off, and they are unaffected by H_2O , air, or bacteria. *E. g.*, 1 kg. Zn-white, 100 g. gelatin soln. (10%), and 70 g. fibrin, are ground up in a drum- or ball-mill, and the resulting emulsion is mixed with 30 g. $HCHO$ (40%). Cf. *C. A.* 9, 158.

Ger., 281,594, Dec. 12, 1913. ÖL- UND FARBFILM-AKT.-GES. In mfg. oil- and paint-films, a suitable breadth and length of weakly sized, strongly absorbent, firm paper, such as pattern paper, is stretched upon a smooth surface and impregnated, on the upper surface, with water-glass. The paper is then removed and satd. on the back with oil varnish. Therefore, after another application of water-glass to the surface, no more moisture is taken up, and the surface becomes smooth. After impregnation the paper is clamped firmly upon a surface, with the water-glass surface up. Oil-varnish or oil-paint is then applied to this surface, with or without a drier, liquid rubber, or the like, by spraying. After 5–10 hrs. a film of oil or paint has formed on the water-glass surface, with its surface free from gumminess, while the under surface does not adhere to the water-glass surface because of the saponifying action of the alkali, and the film can therefore be removed readily. The under side, however, will adhere readily to suitable surfaces, and serve as substitutes for rubber in the manuf. of dust- and water-proof sacks, packing material, wall coverings for building, etc.

Ger., 281,688, Apr. 2, 1914. Addition to 281,687 (*C. A.* 9, 2156). CHEM. FABRIK GRIESHEIM-ELEKTRON. The manuf. of tech. valuable products from organic vinyl esters, according to the principal process, is facilitated by means of catalytic substances, such as organic peroxides, the ozonides, the organic acid anhydrides, in combination with O or agents yielding O (perborates, percarbonates) as well as certain metallic oxides, such as Ag_2O . These agents also influence the properties of the products. *E. g.*, 0.5–1 g. benzoyl peroxide is mixed with 1 kg. vinyl chloroacetate, and the mass is heated carefully in a large vessel provided with a reflux condenser. At $80\text{--}100^{\circ}$ the polymerization is instituted with rapid rise of temp., so that the reaction vessel must be cooled. If the contents are dild. with an indifferent solvent, such as C_6H_5Cl (300 g.), the violent progress of the reaction is moderated. The reaction product is a thick syrup which can be worked further in various ways. *E. g.*, by illumination of the sirup, the valuable solid masses specified in the principal patent

are obtained in a short time, inasmuch as the unaltered vinyl ester polymerizes. These solid masses can also be obtained by driving off the vinyl ester and the diluent *in vacuo*.

Ger., 281,758, Apr. 12, 1913. A. GOTTSCHALK. App. for dissolving dried oils and varnishes and paint films, as well as for softening hard paint brushes, comprizing a hermetically sealed chamber wherein is built a container for the solvent to be volatilized. Below or within the liquid container is a tube system adapted to contain hot H₂O or steam. A porous plate is provided, to be satd. with the liquid.

Ger., 281,759, June 12, 1913. P. HEINRICH. Color atomizer (air brush). Cf. C. A. 9, 2011.

Ger., 281,939, June 27, 1913. CHEM. FABRIKEN DR. KURT ALBERT and DR. LUDWIG BEREND. In mfg. oil-soluble formaldehyde resins, adding to the condensation products from phenols and HCHO or substances which split off such products, all of which are insol. or difficultly sol. in fatty oils, solubilizing agents which are sol. in the resulting HCHO-resins formed, as well as in fatty oils. Resins or resin compds., such as resin acids, resin esters, resinsates, and the like, find application as solubilizing agents. The condensation products from phenols and HCHO or the like are heated for a long time with the resins or the like. Suitable phenols are cresols, naphthols, and their derivs., halogen compds., carboxylic acids, etc., and instead of HCHO, its polymers (trioxymethylene, hexamethylene), or other aldehydes. E. g., 100 g. com. phenol are heated with 70 g. HCHO (40%), and 0.1 g. HCl, for 3 hrs. under a reflux condenser, whereupon the H₂O and excess phenol are removed. To the resin, still in the liquid state, are added 30 g. of colophony, and the mass is heated for about 2 hrs. The resulting yellow resin is sol. in linseed oil, turpentine, benzene, alc., and like solvents, and m. at about 150°. A similar product is obtained with crude cresol and trioxymethylene.

Ger., 282,306, June 1, 1912. Addition to 272,465 (C. A. 8, 2628). E. F. WAENTIG. In the manuf. of linseed-oil and varnish substitutes from animal oils, such as train and the like, the process of the principal patent is modified, with the production of a higher yield, by operating *in vacuo* or at least in a partial vacuum. The temp. in the still is maintained at about 270-85°. At a lower temp. the distn. is protracted materially, and at a higher temp. the breaking down of the glycerides which constitute the varnish may result, thereby decreasing the yield. Air cannot be used in the removal of the finished product from the still on account of the danger of gelatinization. This objection is met by adding to the contents of the still, as soon as the satd. fatty-acid content becomes low, such organic acids or their esters as may remain in the finished product without disadvantage, and serve as diluents or dispersing agents and are also difficultly or not at all volatile. Acids of the unsatd. series, such as linoleic acid, are suitable; also resin may be used. The treatment of train oil with steam of a very high temp. cannot be continued until satd. acids begin to go over, but the heating is discontinued as soon as the formation of the varnish has begun. Since, however, in this case the contents of the still always contain satd. acids, they are after-treated with steam of low temp. (at most 315°), whereby the satd. acids are driven over. The thick oil is always viscous until it finally gelatinizes in case it is boiled too long. In order to prevent gelatinization, organic acids or esters thereof which can remain therein may be added to the varnish. Cf. 281,452 (*supra*).

Swed., 37,362, Dec. 4, 1912. J. AKTSCHOURIN. In the production of colophony from colophony resin, the usual extrn. of the wood by means of alkali, and subsequent breaking of the colophony resin or extrn. of the colophony by means of benzine or ligroin, is effected in the presence of a reducing agent, such as SO₂, sulfite or hydrosulfite.

27. **FATS, FATTY OILS AND SOAPS.**

E. SCHERUBEL.

Behavior of some oils and fatty acids in Mackey's cloth oil tester. W. McD. MACKEY. *J. Soc. Chem. Ind.* 34, 595-7(1915).—Four tables are given showing expts. with olive oil, raw linseed oil, cottonseed oil, olein, and semi-hardened cottonseed oil spread upon cotton wool. Results show that the I no. alone does not give reliable indication as to the behavior of an oil as regards liability to induce spontaneous heating when spread on fiber. E. SCHERUBEL.

The Kambara earth and its bleaching action on oils. S. UENO. Tokyo. *J. Ind. Eng. Chem.* 7, 596-600(1915).—Lab. expts. on Kambara earth (Japanese) which has a marked bleaching action on fatty and mineral oils. This action is affected by the presence of impurities in the oils and varies with the temp. and duration of treatments, the longer treatment being more effective at low temp., and *vice versa*. The presence of air during treatment influences the color of the bleached oil. Contact with H or CO₂ during treatment does not lessen the bleaching power; this is decreased by the presence of free H₂O, strong inorg. acids (except H₃PO₄), or alkalis in the earth as well as by the action of heat. The chem. properties of the oil are not changed by the bleaching action. The spent residual earths have no bleaching power but can be revived. Kambara earth gives a bluish green coloration on admixture with cod liver oil; this may perhaps serve for the identification of the latter. I. M.

Cottonseed crushed and linters obtained. ANON. Bur. Census, *Preliminary report*, March 18, 1915.—The number of establishments crushing cottonseed, the quantity of seed crushed and linters obtained from the crops of 1912, 1913, and 1914 are given. In 1914 there were 880 cottonseed mills in operation; 5,493,899 tons of cottonseed were crushed and 772,270 running bales of linters obtained. R. S. MCB.

The menhaden industry of the Atlantic coast. ROB. L. GREER. Bur. Fisheries, Doc. 811 from Appendix III of Annual Report U. S. Commissioner of Fisheries, for 1914. 27 pp.—Statistical summary, including a description of processes used for cooking, pressing, and drying of material and statement of properties of the oil and scrap. R. S. MCBRIDE.

Large scale treatment of salmon cannery waste. J. W. TURRENTINE. U. S. Bur. of Soils. *Pacific Fisherman* 13, No. 2, 14-5.—A discussion of the relative merits of large scale, centrally located plants and small plants erected as integral parts of or contiguous to a cannery. Large scale operations are described. Cf. C. A. 9, 836. W. H. FRY.

Utilization of salmon cannery waste. J. W. TURRENTINE. U. S. Bur. of Soils. *Pacific Fisherman* 13, No. 1, 15-16.—Salmon cannery waste, consisting of fish other than salmon, and refuse remaining after cleaning, may be used to produce a good quality of oil and dry scrap of satisfactory compn. and appearance. Cf. C. A. 9, 836. W. H. FRY.

Lathering numbers. M. STEFFAN. *Seifensieder Ztg.* 42, 1-3, 23-5, 68-70, 137-8(1915).—A large number of detns. were made on various hard soaps, powders and soft soaps with Stiepel's app., and the influence of saponin and hard water detd. The lathering no. of a saponin soln. is diminished when soap is added and the same is true of a soap soln. when saponin is added. The addition of hard water decreases the lathering properties in proportion to the amt. added because of the formation of Ca and Mg soaps. Hard water does not influence the lathering of a saponin soln. and it is of advantage to add saponin where soaps are used with hard water. The observations of Schrauth, to the effect that free castor oil fatty acids increase the lathering,

were confirmed. Hard water also interferes with the lather under these circumstances. In the case of Dr. Thompson's washing powder the max. lather is obtained with a 0.4 to 0.5% soln., although stronger solns. give more lather, which, however, disappears rapidly. The limit at which lather will appear is about a 0.01% soln. but in the case of Minlos' powder it is 0.1%. The soft soaps are similar to the soap powders, the max. lathering no. being found between 0.3 and 0.5% solns. E. SCHERUBEL.

The adsorptive capacity of talcs and kaolins and their use in the perfume and soap industry. P. ROHLAND. *Seifenfabr.* 35, 459-61(1915).—Talcs adsorb animal and vegetable colors to some extent but to a greater degree blue, violet and red aniline colors, greens and yellowish reds and yellows and brown in the order given. In general the more colloidal a color the more quickly it is adsorbed. The colors contg. the groups NO_2 , NH_2 or $\text{N}=\text{N}$ are poorly adsorbed. Acid colors are well adsorbed. Mixts. of 2 colors may sometimes be sepd. by talc, e. g., aniline red and wool black, the former being adsorbed. In the soap and perfume industries talcs are of advantage because of their power to adsorb and hold odors of all kinds. Kaolins have properties similar to those of talcs. Cf. C. A. 9, 1102. E. SCHERUBEL.

Detection of paraffin wax in beeswax and determination of a new constant for East Indian and European beeswaxes. M. S. SALAMON AND W. M. SEABER. *J. Soc. Chem. Ind.* 34, 461-2(1915).—All pure beeswaxes of European or Indian type yield a clear soln. after sapon. with 0.5 N alc. KOH. If 15% or more of paraffin wax is present, insol. oily droplets are found. If the % falls below 15, the paraffin appears sol. in the soaps present and hence a special method is necessary for its detection. As the paraffin wax would be less sol. in the hot alc. soln. than the hydrocarbon natural to the beeswax, by observing the temp. at which the alc. soln. becomes turbid, some indication is obtained as to the presence or absence of paraffin wax. The limits of temp. at which cloudiness appeared in the hot alc. soln. were 59.5° to 60.5° for European waxes and 56° to 57° for Indian waxes. These points are disturbed by as little as 5% of paraffin wax. They may be detd. as follows: One g. of wax is sapond. over a flame for 1 hr. with 10 cc. of 0.5 N alc. KOH and 10 cc. alc. The flask is removed from the flame, a thermometer inserted and the liquid stirred until the soln. becomes cloudy, when the temp. is read. Carnauba, stearin, insect or Japan waxes do not interfere. Three tables are given. E. SCHERUBEL.

Bleaching of carnauba wax. BELA LACH. Vienna. *Chem. Rev. Fett.-Harz.-Ind.* 22, 40-1, 49-51(1915).—Gray-brown and even "fat gray" quality of Carnauba wax is difficult to bleach; 69-80% white paraffin is added to facilitate bleaching action. The resinous coloring matter is removed by partial sapon. with 8% of a 40% Bé. NaOH soln. at 100° , which yields a second grade product; a subsequent treatment with bleaching blacks or silicates or a mixt. of both and final filtration yields a perfectly white wax. The app. and its operation are described in detail. To facilitate recovery of the wax from the press cake by extn. with some solvent, it is mixed with sawdust while still warm from the press. P. ESCHER.

Detection of phytosterol in animal fats (KÜHN) 12. Constituents of the fruit of the Osage orange (McHARGUE) 12. Turkey red oils from fatty acids (CERBAN) 25.

U. S., 1,143,332 June 15. N. SULZBERGER. A catalyzer for use in hydrogenating oils is formed by reducing Ni silicate by heating with H or hydrazine. Small amts. of Pd may be added.

U. S., 1,143,339, June 15. D. WESSON. A catalyzer for use in hydrogenating oils and fats is made by treating a soln. of $\text{Ni}(\text{NO}_3)_2$ or other sol. Ni compd. with

NH₄OH, applying the ppt. to an inert carrier such as asbestos, heating to drive off volatile compds. and then reducing the Ni by heating in H.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Determination of sugar in bagasse. NOEL DEER. *Intern. Sugar J.* 27, 213-5 (1915).—D. modifies the usual detn. by using larger quantities of material and by concg. the dil. aq. ext. The extractor, shown in the fig., consists of a cylinder 6 in. in diam. and 12³/₄ in. long, having draw-off cocks *B* fitted at the bottom and at 8¹/₄ in. from the bottom. The flat lid *C* carries a reflux condenser *D* and is made to fit tightly by means of a rubber washer and large sized letter clips. The bagasse is contained in a basket *F*, 5¹/₄ in. in diam. and 10¹/₂ in. high, made of centrifugal screen. *H* is a handle. A perforated Pb sheet rests on top of the bagasse to keep it submerged during digestion. To make a detn. fill the extractor to the level of the upper cock with boiling water containing a little Na₂CO₃; drop in the basket, containing 495 g. bagasse; place the lid with the condenser in position and boil the mixt. for 1 hr.; cool to 95°, remove lid, stir the liquid and draw off into a graduated flask 1027 cc. (corresponding to 1000 cc. at lab. temp.). Evap. to less than 200 cc., make up to 200 with Pb(OAc)₂ soln., filter and polarize. With a 40 cm. tube the reading multiplied by 0.2 gives the polarization of the bagasse. In the evapn. an elec. low-water alarm is used to prevent over-concn.

A. GROSS.

The plurality of amyloses. C. TANRET. *Compt. rend.* 159, 530-2 (1914).—T. studied the amt. of sol. starch formed by heating various starches with H₂O to different temps. (45-90°) and comparing these with the amt. formed on heating to 100°. He concludes from the fact that every starch forms a different amt. of sol. starch when treated the same way, that there must be a variety of sol. starches corresponding to each species.

E. M. FRANKEL.

Reduction of copper oxide in reducing sugar determinations (WEDDERBURN) 7.

Brit., 5,900, Mar. 9, 1914. J. J. EASTICK, J. C. N. EASTICK and A. G. EASTICK. In the manuf. of invert sugar or starch glucose, decolorizing C containing little acid-sol. matter is added during inversion. The liquid is preferably agitated by means of a current of air or O, and may be filtered before treatment.

Ital., 132,083, July 24, 1913. A. GUADAGNINI. In a process of extg. from beet roots and other sacchariferous vegetable matter a fermentable liquid as a source of alc., the triturated roots are treated in an open autoclave at 100° until all volatile products have been driven off, the autoclave is closed, and the pressure is raised in such manner that the temp. is brought to 128° during a period of about 1 hr., under which conditions the sugar is converted into glucose. The autoclave is opened to allow the accumulated gases to escape. The liquid product is suitable for alc. fermentation.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

The artificial leather industry during the war. H. ARMIN. *Kunststoffe* 5, 133-4 (1915).—A discussion of conditions in Germany. F. W. SMITHER.

Tannery chemistry in 1914. W. FAHRION. *Z. angew. Chem.* 28, I, 257-9, 268-72, 277-9 (1915).—A review with references to current literature and patents. E. H.

Determination of water-solubles in leather. C. C. SMOOT, III, AND L. E. STACEY. *J. Am. Leather Chem. Assoc.* 10, 363-5 (1915).—The sample to be extd. was packed in an alundum thimble, and the temp. and rate of flow of the water controlled by special app. (described and illustrated). Results can be duplicated within 0.2%. L. B.

How high results in tannin may be obtained. H. G. BENNETT. *Collegium (London)* 1915, 97-102.—Causes of high results are (1) weighing residues only once instead of drying to const. weight, (2) imperfect drying of residues due to too low temperatures, (3) use of too concd. infusions, (4) insufficient cooling of dishes. The first produces high results because the non-tannin residues become dry sooner than the sol. solids. The third cause operates through relatively greater absorption on the part of the hide-powder than in the case of more dil. infusions. In support of the 4th, B. shows that results are more concordant when dishes are cooled 1 hr. than when the time is 20 or 40 min. Cooling overnight is recommended. B. suggests evapg. only 25 cc. of soln. for total and sol. solids, elimination of volatile acids by adding 0.025 g. tartaric acid in soln. to each dish, cooling dishes a uniform time (1 hr.), and the adoption of a narrower range of tannin strength for the infusion. B.'s general conclusion is that where analyses differ in tannin %, the lower is more likely to be correct. L. B.

Analysis of tanning materials for fish nets. G. C. A. VAN DORP. *Collegium (London)* 1915, 71-2.—Cutch has been generally used for tanning fish nets. Another material, probably mangrove ext., showing by the hide-powder method higher tannin content than cutch, gave poor results. Very little material was absorbed by cotton from the mangrove, but much from the cutch. The author suggests that in estg. the value of tanning materials for fish nets a method be adopted which shows the absorption by cotton instead of by hide-powder. L. B.

Detection of sulfite-cellulose extract in mixtures. Committee report. A. C. ORTHMANN. *J. Am. Leather Chem. Assoc.* 10, 359-63 (1915).—Three exts. were analyzed by 4 collaborators, 2 being mixts. containing sulfite-cellulose. The analyses were made by the hide-powder method and by means of "reagent 33" (cf. C. A. 7,

1305, 1820, 3249). Difference in "tannin" detd. by the 2 methods affords a means of estg. % of sulfite-cellulose present.

L. B.

"Alum loading" in raw stock. G. J. LAEMMLE. *J. Am. Leather Chem. Assoc.* 10, 351-8(1915).—Discussion of the practice by hide dealers of adding $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ to green-salted skins to prevent loss of water.

L. B.

Bleaching leather. Two methods with oxalic acid and potassium oxalate. *Le Cuir; Leather Manufac.* 26, 187-8(1915).—The leather is first placed in a tank containing an alkaline soln. which turns the phlobaphenes a dark brown color. A subsequent acid bath neutralizes the alkali and removes the dissolved phlobaphenes. A pure water bath follows and a coat of oil, if necessary, before the usual drying and finishing. Three tanks are used: the first contains a 4% soln. of calcined Na_2CO_3 ; the second a 4% soln. of oxalic acid; and the third, fresh pure water. Dry tanned skins are plunged, thick parts first, into the first tank (130° to 140° F), where they remain 5 min., are allowed to drip, plunged into the third tank (pure water), then placed butts first into the acid soln., where they remain 5 min., are then returned to the pure water tank, are rinsed thoroughly and allowed to drip on a horse. For very defective leather 6% solns. may be used, the first one heated to 150° F. and the time extended to 10 min. With careful work the grain will not become brittle, but the grain side can be set out with a stone or metal when partly dry and given a coat of linseed oil to avoid trouble. With the $\text{K}_2\text{C}_2\text{O}_4$ the method is analogous to that with oxalic acid but the action is less pronounced. It may be used on light or sensitive leathers or when a fine finish is desired. The leathers are immersed for 10 min. in the alkaline bath, a 6% soln. of ammoniacal Na_2CO_3 , at 130° F. The second, or bleaching bath proper, contains 2% $\text{K}_2\text{C}_2\text{O}_4$ and 6% HCl . The time is from 5 to 10 min. A pure water bath precedes and follows the second soln. The leather would become hard and brittle if the time were prolonged. There is no free acid in the finished leather, because the acid entering in the acid bath was neutralized at once by the alkali from the alkaline bath.

Recovery of sludge from the sulfide process of depilating skins. JOHN HELFRICH. *J. Am. Leather Chem. Assoc.* 10, 367-9(1915).—The sludge is pptd. by adding 0.12% H_2SO_4 and 0.02% $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$, and filtered on a sand bed. The product has 15% H_2O . Of the dried sludge, 8.53% is N, of which 3.9% is available as fertilizer.

L. B.

Notes on the alundum thimble. F. H. SMALL. *J. Am. Leather Chem. Assoc.* 10, 366-7(1915); cf. G. A. 8, 1031.—Difficulties previously met in using the alundum thimble in a Teas extractor, due to steam passing between the thimble and the walls of the extractor, are overcome by making the thimble with a tapering top and fitting a rubber gasket to the annular space.

L. B.

U. S., 1,142,953, June 15. F. B. GALLIVAN. Waterproof leather-board is made by mixing a pulp formed of fibers of tanned leather with 10% of the gelatinous ppt. formed by the reaction of Na_2CO_3 with $\text{Al}_2(\text{SO}_4)_3$, FeSO_4 , MnSO_4 or $\text{Cr}_2(\text{SO}_4)_3$. Vegetable fiber, e. g., jute, may be added.

Brit., 5,863, Mar. 7, 1914. F. HIRSCH. Chrome tanning. See Ger., 274,549 (C. A. 8, 3136).

Ger., 281,453, Feb. 24, 1912. M. HÖNIG. In mfg. a tanning extract from sulfite cellulose back water, adding to the water so much acid, forming insol. salts with Ca

(H_2SO_4 , $\text{H}_2\text{C}_2\text{O}_4$), that all the ligninsulfonic acids in the liquors are liberated, together with the volatile acids, and all the Ca combined with these acids is pptd. The resulting ext. is low in ash, so that alkalinity of the tanning liquors obtained therefrom is not to be feared. Furthermore, the ext. is rich in substances which are taken up by the skin and which are not colloidal. By reason of its high content of free organic acids it effects, in the first stages of tanning, a rapid and complete deliming of the skins, together with an active swelling and a prompt tanning action. If it is employed in combination with vegetable tanning materials for complete tanning, it aids in securing a more complete utilization of the vegetable material on account of its solvent action, and shortens the tanning process because of its soft, swelling action. Cf. C. A. 8, 591.

Ger., 281,484, May 18, 1913. BADISCHE. Tanning animal skins by treating them with H_2O -sol. amorphous aromatic, hydroxy compds. containing in the mol. 2 or more aromatic nuclei which contain not more than 1 OH group in a nucleus, which are united with each other by 1 or more at. groups or polyvalent ats., which contain, besides OH, 1 or more other salt-forming acid groups and which ppt. glue or gelatin soln. Other tanning or indifferent substances may be added also. E. g., the well limed and soaked hides are immersed in an approx. 2.5 % aq. soln. of sulfonated dimethyldihydroxydiphenylsulfone rendered moderately acid. After about 10 days the tanning process is completed. A single or repeated dyeing follows. The finished leather is neutralized, oiled, and dried. For the production of the sulfonated dimethyldihydroxydiphenylsulfone, 50 parts dimethyldihydroxydiphenylsulfone (obtained by heating *o*-cresol with H_2SO_4) at the ordinary temp. are stirred with 200 parts of 23% alum until the product has become sol. in H_2O . The reaction product is poured upon about 200 parts ice, and the excess H_2SO_4 is removed from the soln. by lime or baryta. The resulting soln. is employed either directly or after further concn. Cf. C. A. 9, 1857.

Ger., 281,717, Nov. 5, 1909. Addition to 200,519. O. RÖHM. In tanning hides, the neutralization of the skins obtained according to the principal patent can be effected by allowing the enzyme of the pancreas to act on the skins in a liquid containing salts and in a state of decompn. or fermentation. The resulting acids have a neutralizing action, and the skins taken from the soaking tank need only a short rinsing to prepare them for tanning.

Ital., 131,163, Apr. 4, 1913. P. L. MARTY and F. M. PRADON. A dye may be extd., in the usual manner, from *Rhus pentafilla*, which, when decolorized, serves as a tanning agent.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Increased rubber yield in Malay States. CASPAR L. DREIER. Vice Consul, Singapore. *Commerce Reports* 157, 92-3(1915).—Comparison of 1914 production with that of 1913. E. H.

A new machine for the preparation of vulcanized rubber for analysis. R. WHEATLY and B. D. PORRITT. *J. Soc. Chem. Ind.* 34, 587-8(1915).—Because of the great variation in phys. properties, shape and character of rubber goods careful selection and prepn. of the sample, fine division, and thorough mixing are necessary to ensure reliable analytical results. The methods heretofore proposed for the reduction of

samples to a fine state of division are briefly reviewed. As a result of experience in dealing with a large variety of samples of different qualities the authors have decided that rasping is in general the most satisfactory method. A machine for accomplishing this has been devised. The abrasive surface consists of a circular file, made from a 1-inch diam. rod of file steel, the cutting edges being parallel to the axis. This is mounted in bearings set on a bed plate, and has a double pulley keyed to one end. A small elec. shunt-wound motor, of $\frac{1}{8}$ h. p., furnishes the power to drive the file at 1200-2400 revolutions per min. These rotational speeds correspond to peripheral speeds of 314 and 628 ft. per min., resp. The rasped rubber falls into a detachable tray placed below the file. For the harder qualities of rubber the low speed gives the more satisfactory results, while a better result is obtained by increasing the rate of revolution when dealing with soft material. The comp. of the rubber was found to be unaltered by the heat developed during treatment. Care must be taken to protect the finely divided material from oxidation if not immediately used for analysis or if preliminary drying is required, and to prevent oxidation during the course of analysis. The present app. is ineffective in the case of raw rubber and reclaimed rubber.

E. J. C.

The function of litharge in the vulcanization process. H. P. STEVENS. *J. Soc. Chem. Ind.* 34, 524-6(1915); *India Rubber J.* 49, 846-8(1915).—Analyses of mixes containing 100 parts rubber, 5 parts S, and 0 to 70 parts PbO cured 2 hrs. and 3 hrs. at 132° , show that the curing effect is due to the heat generated by the reaction $4\text{PbO} + 2\text{S}_2 = 3\text{PbS} + \text{PbSO}_4$. (Cf. *Gummi-Markt.* 1911, 123; *Gummi-Zig.* 15, 710, 748; 29, 424, which give the method for the detn. of these reaction products). S. concludes that a max. curing effect is obtained with a mix containing $17\frac{1}{4}$ parts PbO in which the amt. of S is just sufficient to cure the rubber fully, and to convert the whole of the litharge into PbS and PbSO₄. Analysis shows a max. of S combined with rubber in both cures of this mix, the S being distributed as follows: combined S 3.37, free S 0.33, S as PbS 1.05 and S as PbSO₄ 0.25 parts. Further additions of PbO cause a reduction in the coeff. of vulcanization, larger amts. of PbS and PbSO₄ being formed. The free S drops suddenly with both cures in the sample containing $17\frac{1}{2}$ parts PbO. Even with large amts. of PbO a little free S always remains. S. states that the cured samples containing $17\frac{1}{2}$ parts and more of PbO showed no sign of "bloom" after standing several months.

U. S., 1,143,152, June 15. R. T. VAN VALKENBURG. A composition for closing punctures in pneumatic tires is made by heating a mixt. of asbestos 4.75, "alabastine" 5.5, NaCl 10, charcoal 1, Fe₂O₃ 1 and H₂O 55 parts at about 113° until thick, adding flour 2 and corn meal 1.5 parts and agitating the mixt. while boiling.

Brit., 4,955, Feb. 25, 1914. W. E. MUNTZ. The fabrics used as foundations in vulcanized rubber goods are preserved from the effects of SO₂ and H₂SO₄ by impreg-

nating the fabric or the rubber coating or the coated fabric with any of the following substances: (1) additive compds. of NH_3 with salts such as ZnSO_4 and MgSO_4 ; (2) HOAc or other organic acid, which is afterwards acted on by NH_3 or other alkali; (3) NH_3 and CO_2 applied together or in succession, preferably under pressure during vulcanization; (4) NH_3 applied alone, preferably during vulcanization. Cf. C. A. 9, 2008.

Brit., 5,464, Mar. 3, 1914. P. M. MATTHEW. Vulcanizing rubber goods, such as belting, and, if desired, calendering and compressing them with patterns, by leading the goods in a sinuous path around and between the surfaces of heated rotary cylinders.

Fr., 468,493, Feb. 16, 1914. W. E. MUNTZ. Rubberized cotton fabric is protected from the destructive action of the SO_2 and H_2SO_4 which form gradually in contact with the air, by treating the fabric, before impregnating it with rubber, with a soln. of $\text{Ba}(\text{OH})_2$ (3%) or with salts of Ca, Zn, Cd, Pb, or Al, and then with $(\text{NH}_4)_2\text{CO}_3$. Cf. Brit., 4955 (*supra*).

Ger., 281,966, Aug. 2, 1913. BADISCHER. In the manuf. of polymerization products from butadiene, its homologs and analogs, the polymerization by means of Na and like metals results in the rapid production of a new Na-caoutchouc which in many respects differs in its properties from the product obtained according to 249,868 (C. A. 6, 3200), if the said metals are allowed to act with the addition of metal hydroxides or organic hydroxyl compds. E. g., 100 g. isoprene are shaken up with 3 g. Na in wire form and 4-5 g. finely powdered anhydrous NaOH , for 2-3 days in a closed vessel at the ordinary temp., until the Na is finely divided and the liquid has begun to thicken. The mass is then allowed to stand, when the Na and a portion of the NaOH settle to the bottom. The supernatant mass thickens rapidly and is solid after about 6 days, so that it cannot be removed from the vessel in a solid mass. The mass is separated from the small portion containing Na and freed from a small amt. of volatile constituents *in vacuo*, and, if necessary, from alkali by washing. Cf. C. A. 8, 435.

Norw., 24,923, July 22, 1913. M. BARRICELLI. In mfg. an elastic mass as a rubber substitute, 4 kg. bone glue, 1 kg. gelatin, 3 kg. H_2O and 3 kg. glycerol are melted together to a sludgy mass, which is mixed with 0.05 kg. S, and 500 cc. glacial HOAc is added later. The resulting mass is then warmed for some time on the H_2O bath, and immediately before molding, 500 cc. HOAc and 1 liter formalin are added. The amts. of H_2O and of glycerol can be altered according to the desired elasticity of the final product. A very strong mass consists of 10 parts gelatin, 5 of crude glycerol, 2 of pure glycerol, 3 of H_2O , 0.25 of $\text{K}_2\text{Cr}_2\text{O}_7$, 0.25 of $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$, 2 of sirup, 0.05 of S, and 0.1 of Al powder.

Swed., 36,863, July 31, 1912. H. K. A. S. VON EULER-CHELPIN. Mfg. isoprene by conducting turpentine oil vapors over an ignited mass consisting of finely divided Ni to which has been added 2-15% Mn or Os.

Swed., 37,268, Mar. 19, 1912. J. OSTROMISSENSKIL. In the manuf. of isoprene and its homologs, the crude material is converted into the gaseous form in the presence of readily condensable and sufficiently stable hydrocarbons, such as aromatic hydrocarbons, benzene, toluene, xylene, naphthalene, benzine, petroleum ether, etc., and then heated to high temps. CHEMICAL ABSTRACTS

Vol. 9.

SEPTEMBER 10, 1915.

No. 17.

I. APPARATUS.

L. C. JONES.

Modern apparatus for the preparation of hydrogen. OSKAR KAUSCH. Berlin. *Chem. App.* 2, 125-8, 141-4(1915).—A review, with 16 cuts. J. H. MOORE.

An automatic filter washer. J. M. PICKEL. *Chem. News* 112, 3-5(1915).—P. describes improved forms of an app. previously reported (cf. *J. Am. Chem. Soc.* 23, 589(1901)), for washing out fertilizers, water-sol. ammoniates, phosphates, etc. The app. may consist of any number of elements for the simultaneous washing of more than one filter. In one form each element (a 300 cc. percolator with its siphon) is separate and distinct, and the charging of each with H_2O requires a separate and distinct operation. In another form each element is so connected with all the others that all are charged with H_2O by one and the same operation. This is accomplished by means of a superimposed vessel of sheet Cu with a removable lid to exclude dust, and divided into H_2O -tight compartments by partitions reaching only part way to the top. Each compartment holds about 260 cc. of H_2O . In the bottom of each compartment (see fig.) is a small hole, *a*, about 5 mm. in diam.; over this hole is soldered a galvanized Fe tee, *b*. In one branch of *b* is inserted by means of a stopper the glass tube *c* for a H_2O gage; into other branch of *b* is screwed an ordinary brass gas cock, *d* (male, small size). To the nozzle is attached the siphon (by means of a stopper provided with an air-vent). This consists of a glass tube, *e*, 10 cm. long and 1.8 cm. in diam. (inside). The lower end of this tube is fitted with a stopper carrying a small glass tube, *f*, about 4 mm. in inside diam., 9 cm. long and V-shaped (ground sloping on 2 sides) at upper end which extends about 5 cm. into *e*. Over the V-shaped tube, and supported by it, is a cap (glass tube), *g*, about 7 mm. inside diam. and 4.5 cm. long; it is closed at its upper end. The siphon delivers 10-15 cm. of H_2O at each overflow. The flow of H_2O , drop by drop, into the siphon is so regulated by the cock that the siphon delivers H_2O to the funnel underneath more slowly than the H_2O runs out of the funnel. Intermittent washing is thus effected. In the large filtering funnel is placed an inverted small funnel to throw the H_2O around over the edge of the filter paper.

F. W. SMITHER.

Use of the Zeiss interferometer for gases. R. LUCION. *Bull. soc. chim. belg.* 27, 343-6(1913).—The type of interferometer studied by Rayleigh and improved by Zeiss by the introduction of optical compensation was found to afford as great a degree of accuracy in the detn. of small amts. of air in industrial H as the chem. method which depends upon the weighing of the H_2O produced by combustion, and the time required for a detn. was much less than in the latter case (*i. e.*, after a calibration had once been secured for the gas in question). This interferometer consists essentially of 2 parallel, twin tubes which are illuminated through a collimator at 1 end by means of an elec. lamp; at the other extremity are a lens and a graduated head (which actuates an op-

tically compensatory plate). If the 2 tubes contain the same gas the 2 portions of the field of vision show identical interference bands; if a different gas is placed in 1 of the tubes the displacement of the interference bands in $\frac{1}{2}$ the field of vision may be nullified by means of the compensatory plate, the movement of the latter being referred to the graduated head by which it is actuated. The interferometer must, therefore, be calibrated from mixts. of known compn. Inasmuch as H_2O vapor acts as a gas it is necessary to dry both the comparison gas and the gas to be tested. Since gas pressure exerts an influence on the position of the interference bands it is necessary to connect the containing tube with the air by means of a rubber tube attached to an open capillary glass tube (to prevent appreciable diffusion); measurements are thus made at atm. pressure, the connection with the atm. being open only at the moment of reading. The method permits the detn. of only 1 variable, i. e., it is only applicable to binary mixts. The principle of chem. absorption may be applied to the detn. of CO_2 in flue gases, for instance, by filling the comparison tube with the dried flue gas, while the other tube is filled with the same gas (dried) freed from CO_2 by passage through KOH soln. In the particular detn. under consideration (the estimation of air in industrial H) the interferometer was calibrated by means of synthetic mixts. containing pure H or industrial H which had been subjected to careful chem. analysis; a variation in the air content of industrial H of 0-10.19% by vol. corresponded to a variation of 870-780 in the reading of the scale to which the motion of the compensatory plate was referred. It is possible, by means of this method, to attain such accuracy in the detn. of air in CO_2 or CH_4 that the error does not exceed $\pm 0.01-0.02\%$.

H. S. PAINE.

Notes on centrifugals. G. BARNICK. Leipzig. *Chem. App.* 2, 152-5(1915).

F. A. HARVEY.

The determination of the specific gravity of gases, and the reduction to normal conditions. M. HOFSSÄSS. *J. Gasbel.* 58, 49-51(1915);

see fig.—The app. is inserted in the gas line and washed out by closing *e*. A sample from *a* to *b* under the pressure of the main is allowed to escape through *d*, and the time it takes the manometer *h* to fall a fixed distance is noted. The lower mark on *h* is movable and is set so that with air the time is 1 min. For calibrating with air, the 3-way cocks *a*, *b*, and *c*, and the leveling bulb *g*, are so manipulated that the app. is washed out with air first. A slide rule for calcg. the results is shown, and a set of curves is given from which may be read the factor for reducing the vol. of a gas satd. with H_2O , to 0° and 760 mm.

W. L. BADGER.

A new thermoregulator. EDV. BJÖRNSSON. Lund.

Z. Instrumentenk. 35, 74-5(1915).—A spiral of thin Cu tubing, filled with toluene or pure paraffin oil and closed at both ends, is connected by a fine Cu tube to a small reservoir and to a second, fine, thin-walled Cu tube. This second tube is flattened until it is almost closed and is bent into the quarter arc of a circle. On the end of the tube

is a pointer with Pt contacts, which make contact with Pt points if the pointer moves up or down. By a valve the reservoir may be cut off from the tubing at any desired

temp., leaving a closed system full of liquid. Expansion of the enclosed liquid straightens the flattened Cu tube. The elec. contact is utilized in gas heating to actuate a magnet which draws a lever down, pinching the rubber tube of the gas burner. By means of 2 screws the motion of the lever is limited to give a max. and a min. flame. In elec. heating the contact throws in or out an auxiliary coil. Advantages are: rapidity of adjustment, 10 min. being sufficient for the fine adjustment after the rough adjustment is made; the app. is entirely free from friction or lost motion; the liquid is in a closed container, thus avoiding loss or contamination; constant temp. may be maintained with the regulator near 100° within 0.05° with elec. heating and within 0.1° with gas heating.

F. A. HARVEY.

Comparison of mercury thermometers with platinum thermometers. F. HOFFMANN AND W. MEISSNER. Reichsanstalt. *Z. Instrumentenk.* 35, 41-9(1915).—Thermometers of Jena glass 16^{III} and 59^{III} previously investigated by Weihe and Grütz-macher (*Z. Instrumentenk.* 32, 217-29(1912)) have been further studied over the range 100° to 300° by comparison with a Pt resistance thermometer. The thermometers of glass 16^{III} were of solid stem; those of glass 59^{III} were both of solid stem and milk glass scale. The potentiometer method was used with the resistance thermometer, which consisted of Pt wire, with 4 leads, wound on mica. The results are expressed in the formulas: For Jena glass 16^{III} $g_t = t(t-100)(-46.40 \times 10^{-8} + 2.8872 \times 10^{-7}t + 4.96 \times 10^{-11}t^2)$; for Jena glass 59^{III} $g_t = t(t-100)(-19.16 \times 10^{-8} + 3.0729 \times 10^{-7}t - 0.56 \times 10^{-11}t^2)$ where g_t gives the difference between the mercury and resistance thermometers. The value for 59^{III} is the mean for the 2 classes of thermometer. The different forms vary up to 0.03° from the mean.

F. A. HARVEY.

New voltage regulator. G. E. GRAU. *Elektrotechn. Z.* 36, 63-6(1915).—The construction and operation of the high speed voltage regulator of the Siemens-Schuckert Co. is described. Its applicability for power and speed regulation is discussed and a new arrangement in which the voltage relay is provided with a special reverse attachment, by means of which a premature interruption of the regulation process occurs, is described. This arrangement provides for greater speed of regulation. Cuts and diagrams are given.

Ger., 282,540, May 16, 1914. ATMOS G. M. B. H. Detection and estimation of mineral deposits by measuring the sp. gr. of the earth with the aid of a closed liquid manometer wherein the sealing liquid (Hg) confines within the short limb a vol. of gas under pressure. By regulation of the temp. the gas is brought to a constant vol. so that the sp. gr. can be detd. when the app. is at that specific temp. The U-shaped manometer, *a a'*, filled with Hg and closed at both ends, is mounted in a heat-insulated Cu container *b*, together with a thermometer *c* and a stirring device *d*. Above the Hg in the limb *d* is a vacuum, and the space above the Hg in the limb *a'* is a gas, as N. An insulated metallic circuit extends from the point *e* (downwardly directed and adapted to contact with the surface of Hg in the limb *a'*), out through the casing, through a telephone receiver *g*, a source of a. c. (primary and secondary coils) *h*, and to the Cu vessel *b*. The connection between the Cu vessel and the Hg in the manometer is made through a cock *i* which rests upon the bottom of the Cu vessel, and which is closed during transportation of the app. to prevent the entry of the N from the short limb into the vacuum space over the Hg in the limb *a*. By means of the telephone receiver *g* the contact between the point *e* and the Hg in limb *a'* may be detected. The Cu vessel is filled with H₂O, or other suitable liquid, the temp. of which may be read upon the thermometer. The stirrer equalizes the temp. of the liquid, as does also the good heat conducting surface of the vessel *b*. The manometer consists of a material (such as invar nickel-steel and quartz glass) whose coeff. of expansion may be neglected. The detn. of the sp. gr. of the earth is made by noting the temp. of the liquid in the container *b* at the instant when the point *e* touches the Hg surface in the limb *a'*. From these temp. readings at points with different sp. gr., considering that the temp. of the liquid corresponds to that in the manometer limb *a'*, the difference in sp. gr. may be calcd. Under suitable conditions, the sp. gr. at different points varies as the abs. temp. of the gas in the limb *a'*. The results are sufficiently accurate for practical purposes.

The structure of complex atoms and the changes of mass and weight involved in their formation. WILLIAM D. HARKINS AND ERNEST D. WILSON. *Proc. Am. Acad. Sci.* 1, 276–83(1915).—The authors calc. the change in mass which occurs when a positive and a negative electron are brought close together. The effect of the overlapping of the fields of the two electrons is expressed in terms of the "mutual electromagnetic momentum" as $G = \pm (\mu K^2 e^3 / 8c^2 r^3) - 4\pi \int_0^\infty \int_0^\infty (y^2 dy dx / \sqrt{[(x-a)^2 + y^2][(x+a)^2 + y^2]})^{3/2}$ or $G = \pm \mu K^2 e^3 / 4\pi r a^2$ and $\Delta m = e_1 e_2 / 4\pi r a c^2$ where Δm is the change of mass due to the overlapping of the electrons, or $\Delta m/m = 3R/d$ where R = radius of the electron, and d is the distance between the centers of the electrons and $\Delta m/m$ represents the fractional change of mass. Taking R as the radius of the positive electron and -0.77% as the "packing effect" (see following abstracts) the distance apart of 1 positive and 1 negative electron would be 400 times the radius of the + electron. Though this case is simpler than that for any known complex atom, since the helium nucleus or the alpha particle is assumed to contain 4(+) and 2(−) electrons, the theory accords well with the diameter of the gold nucleus as calcd. by Rutherford to be less than 6.8×10^{-12} cm. According to the theory presented the gold nucleus consists of about 197 (+) hydrogen nuclei and 118 (−) electrons which must be packed in this extremely small space.

W. D. H.

Atomic structure. I. Changes of mass and weight involved in the formation of complex atoms. W. D. HARKINS AND E. D. WILSON. *J. Am. Chem. Soc.* 37, 1367-83 (1915).—The first 27 elements do not have at. wts. which are whole numbers, but they differ from whole numbers by a constant percentage amt., namely -0.77% . This difference has been called the "packing effect," and it represents the decrease in mass, and presumably in weight also, which must take place if the other atoms are built up from H atoms. If the at. wt. of H ($O = 16$) be decreased by this "packing effect" %, it is then a whole no., and all the elements built up from H atoms as units (*i. e.*, all those whose packing effect is -0.77%) have also at. wts. which are whole numbers. Evidence is presented to show that the electrons and positive particles are packed exceedingly closely in the nucleus of a complex atom, as a result of which the electromagnetic fields overlap to a considerable extent, which would mean that the mass of the atom ought to be equal to the sum of the masses of the individual particles from which it is built. Prout's hypothesis in the original form was not valid, and is here presented in a new form, that the atoms are composed of H atom nuclei. The probability that the sum of the deviations of the at. wts. (basis of $O = 16$) from whole numbers should be as small as it actually is by accident for the first 27 elements was calcd. to be one chance in 15 million, but a change of only 0.77% from the O basis to that of H gave one chance in 10 that the at. wts. should be by accident as close to whole numbers as they are. The atomic weights of the elements are represented by the formula $W = 2(n + n') + \frac{1}{2} + \frac{1}{2} (-1)^{n-1}$ where n is equal to zero for the lighter elements.

II. Structure of complex atoms. The hydrogen-helium system. *Ibid* 1383-96.—A scheme (see below) is presented to show that the system which has been found to apply to the at. wt. and valence relations of the members of each radioactive series also holds true as well for the lighter atoms. That is, beginning with He, which has an even at. number, the addition of each mass of 4 or one He atom, adds 2 to the at. number and also increases the valence by 2. Beginning with Li, which is represented by $He + 3H$, the same rule holds for the members of the odd numbered groups. The theory is shown to be in accord with the astronomical evidence for the evolution of the elements from H and He. The He nucleus or the α particle is supposed to be made up of 4 positive H nuclei and 2 negative electrons. With the exception of Ne, Si, Mg, and Cl, the elements with at. wts. up to 59 (Co) could be represented *very exactly* as composed of H and He, and in all cases except Be, of He alone or of He and H_2 . It was concluded that isotopes do not exist for these elements, except the 4 mentioned, to any considerable extent. The 4 elements also accord with the system but less exactly. For elements above Co the tendency for the at. wts. to approximate whole numbers seems entirely to disappear, or is covered up by the appearance of some other

Increment from series 4 to series 5 = 6 He.

new series. The elements are thus supposed to be "atomic compds." (not chem. compds.) of H and He. The fact that A has a higher at. wt. than K is shown to be due to the fact that at this point in the system there is a tendency to take on He atoms more rapidly, and this rule is followed by all of the members of series 4 of the Mendeléeff table except K and Ca. A thus contains one more He group than corresponds to the structure of the elements of series 3 and this increases its at. wt. by 4. III. Recent work on the structure of the atom. *Ibid* 1396-421.—A review. E. B. MILLARD.

Integral atomic weights. F. W. DODD. Weymouth, England. *Proc. Trans. Nova Scotian Inst. Sci.* 13, 216-27 (1912-13).—The suggestion is put forward that the accepted at. wts. are fractional parts of a series of higher or integral at. wts., which more correctly represent the properties and constitution of the ats., except in the matter of wt. There is evidence that these integral at. wts. are a real function of their respective elements. From these integral at. wts. the following may be inferred: (a) The heavier elements are built up from the lighter elements with probably H, He and possibly Li largely as constituents, these sub-atoms being conjoined in some vibratory system which renders a part of their material unnecessary to the structure of the complex atom; for if the at. multiple, or the integral at. wt. be taken as proportional to the number of ultimate sub-atoms, constituting any given atom, then the excess of these magnitudes over the accepted at. wt. may be considered proportional to the loss of material in the formation of the atom. (b) The quantity of missing material is a very simple function of the closeness of the combination, *i. e.*, of the d. of the substance. (c) The sp. heat of an element depends more upon the number of ultimate sub-atoms, in its main atom, than upon the actual wt. of the main or complex atom. (d) With a given number of sub-atoms, the m. p. is a direct function of the quantity of missing material, so that the m. p. and sp. gr. curves are similar so long as the number of sub-atoms (*i. e.*, the at. multiple) remains const. H. JERMAIN CREIGHTON.

Electrical activation of nitrogen. A. KORNIG. *Z. Elektrochem.* 21, 267-86 (1915); cf. *C. A.* 7, 3053; 8, 626, 2283, 2971.—Mol. N reacts at ordinary temps. with Li and with other elements (metals) at temps. where no dissociation into atoms could be found by gas-density methods. Either mol. N must possess a kind of residual activity (or secondary valence) which allows it to react, or there is a physically unmeasurable but chem. significant quantity of N in the dissociated state at ordinary temps. The latter was considered more probable. The reaction velocity of Li (*s. g.*) with N was detd. only by its speed of vaporization from the solid or liquid state (which governs the v. p., and is dependent upon temp.), and the "resistance at the surface" caused by a more or less adherent film of solid reaction product. When a monoatomic Li mol. strikes 3 N atoms, N_3Li will be formed; a large reaction velocity was not to be expected on account of the extremely small concn. of N atoms. A full discussion of Strutt's work (*C. A.* 9, 1561), of elec. activation by impact ionization, of N atoms as intermediate products, afterglow, etc., has been given. The N after-glow may be produced in the entire absence of O or O compds. Traces of metal vapor or dust act unfavorably on the N after-glow by forming nitrides and thus using up the active N and by a catalytic retardation of activation; traces of O oxidize the metals and destroy their retarding effects. High tension d. c. arcs can also activate N as well as condenser sparks, and N so formed reacts with C_2H_4 , C_2H_2 , C_4H_{10} , NO and metals, but not with H, CH_4 , H_2O , O_2 or O_3 . Pure O at low pressures showed a weak glow after passing through an elec. discharge, and the glowing O formed NO with N. This is the first instance of an oxidation of N at low pressures outside of the elec. discharge. At atm. pressure the reaction took place only inside the discharge area. The presence of active H outside the discharge was not established with the present app., doubtless because its "activity" disappears much more rapidly than that of N or O. E. B. M.

Numerical relationships between electronic and atomic constants. H. S. ALLEN. King's Coll. *Proc. Phys. Soc. London* 27, 425-31(1915); *Engineering* 99, 687(1915).—The quantity hc , where h is Planck's const. and c = velocity of light has the dimension of (elec. charge)². Putting $2\pi e^2/hc = \sqrt{p}$ where e = electronic charge, the charge e in c. s. u. = $9 p^{10^{-8}}$, $e/m = p^{10^{12}}$, "at. mass of electron" = $10 p$, and other derived quantities depending on e , m , and c can be expressed in terms of simple integers, powers of 10, p and π .

PAUL D. FOOTE.

Report of the committee on nomenclature and symbols. *Proc. Phys. Soc. London* 26, 381-4(1914).—Nomenclature and symbols for numerous physical quantities are recommended by a committee composed of J. J. Thomson, H. L. Callendar, A. Campbell, C. Chree, G. Carey Foster, W. Eccles, George Greenhill, A. Russel, R. J. Strutt, S. P. Thompson, and W. Watson.

PAUL D. FOOTE.

The thermochemistry of compounds of copper and aluminium. LUIGI ROLLA. Univ. Genoa. *Gazz. chim. ital.* 45, I, 192-6(1915).—In calculating the sp. heat of several compds. between metals Schimpff (*C. A.* 4, 1129) and Schübel (*C. A.* 8, 2837) showed that the deviations from the law of Neumann and Kopp can not be attributed to the heat of formation nor to the position of the compd. on the fusion curve as was shown for Cu_3Al , CuAl and CuAl_2 . However, in Lindemann's formula for the atomic frequency of an element in which this value is calcd. from the atomic frequencies of the elements the sp. volumes are used as well as the abs. m. ps. R. detd. the sp. vols. of the compds. named and finds a diminution with respect to the sp. vol. of the free elements which is large enough to affect the values for the atomic frequency and therefore also the sp. heats. In order to det. also whether there is any relation between the heat of formation and the deviations from the law of N. and K. the heats of formation of the 3 compds. were detd. This was done by detg. the heat of formation of the bromides of Al, Cu and of the 3 alloys in $\text{Br}_2\text{-KBr}$ soln. The values obtained were: CuAl 32.38, CuAl_2 23.29 and Cu_3Al -13.33 Calories, resp. The strongest exothermic compd. is formed with the least contraction. There is apparently no relation between the heat of formation of alloys and the deviation from the law of Neumann and Kopp.

E. J. WITZEMANN.

The electrical resistance of acetic acid in the solid and liquid phases. J. H. L. JOHNSTONE. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 13, 191-208(1912-13).—The following satisfactory methods have been investigated and used for the measurement of high elec. resistances: (1) For the measurement of resistances between 10^4 and 10^8 ohms an alternating current "bridge" method may be employed, in which the telephone or galvanometer of the Kohlrausch app. is replaced by an electrometer and two of the resistances by capacities; (2) using a sensitive galvanometer and a d. c., resistances ranging from 10^8 to 10^{10} ohms may be conveniently measured, since here the polarization effect will be small as compared with the total resistance, because the current flowing through the cell will be minute; and, furthermore, as the applied e. m. f. is large, the "e" term will be a small fraction of the total e. m. f.; (3) for greater resistances than 10^{10} ohms an electrometer may be substituted for the galvanometer in (2). The sp. resistance of AcOH in the solid and liquid phases has been measured at temps. ranging from -80° to 47° . Sudden changes were observed at the m. and the eutectic points. The resistance in the solid phase above the eutectic point was found to vary in a peculiar manner as the temp. changed. This variation has been explained. The effect of small quantities of H_2O on the resistance of the acid has been studied, the results obtained explained, and it has been shown that the cond. of the acid above the eutectic point is due almost entirely to the presence of this H_2O . The temp. coeff. in the liquid phase has been found to be nearly const. and equal to 0.04, while in the solid phase it varies from 0.30, at -43° , to 0.25 at 70° .

H. JERMAIN CREIGHTON.

Confirmation of the law of Bunsen and Roscoe by means of the photochemical reaction of hydriodic acid. E. JIMENO GIL. *Anales soc. espan. fis. quim.* 12, 534-9 (1914).—G. studied the law of Bunsen and Roscoe according to which $i t = \text{const.}$ (i = intensity of light and t = period of illumination). An elec. arc and a Hg lamp in quartz were employed as sources of light and 3 vessels (either cylindrical in shape or with rectangular sides) containing the reacting medium were placed at distances from the source of light which bore the relation 1, $1 \times \sqrt{2}$, 2 to each other; the actual distances in 2 series of expts. were 20, 37.5, 40 cm. and 30, 42.5, 60 cm. Each of the vessels contained 40 cc. of a soln. composed of 2 g. KI, 100 cc. H_2O and 50 cc. HCl. The solns. were kept at const. temp. ($19-21^\circ$ for the entire series) in each expt. Heating of the solns. by the light was avoided by passing the rays through a H_2O filter. O was passed simultaneously and consecutively through the solns. so that the O conc. was const.; after an equal period of illumination for each of the solns. the amt. of I formed was detd. by titration with 0.02 or 0.01 N $\text{Na}_2\text{S}_2\text{O}_3$ soln., the HCl having been added to the KI soln. at the moment of placing the latter in the appropriate vessel. A similar soln. was kept in the dark for the same period of time as in the case of the 3 exptl. solns. proper and the vol. of standard $\text{Na}_2\text{S}_2\text{O}_3$ soln. required for the titration of liberated I was subtracted from the vol. of $\text{Na}_2\text{S}_2\text{O}_3$ soln. required in each case; the final values were, therefore, a measure of the catalytic action of light. For the distances 20, 37.5, 40 cm. the corresponding corrected vols. of $\text{Na}_2\text{S}_2\text{O}_3$ soln. were 2.0, 4.1, 8.0 cc., resp.; the corrected vols. of the latter soln. were 0.3, 0.58, 1.25 cc., resp., for the distances 30, 42.5, 60 cm. For the distances 20, 37.5, 40 cm. with different periods of illumination of 20, 40 and 80 min., resp., the corresponding corrected vols. of $\text{Na}_2\text{S}_2\text{O}_3$ soln. were 1.7, 1.7, 1.75 cc.; for the distances 30, 42.5, 60 cm. with varying periods of illumination of 20, 40 and 80 min., resp., the corresponding corrected vols. of $\text{Na}_2\text{S}_2\text{O}_3$ soln. were 0.95, 0.98, 1.00 cc. The law is, therefore, apparently confirmed, although slight discrepancies appear. Although the above reaction is especially influenced by blue rays of the region λ 436 the red rays also have considerable effect; the liberation of I causes a progressive increase in the intensity of the red coloration of the soln., thus producing absorption of all rays except the red and diminishing the velocity of the reaction. It is, therefore, advisable to use either dil. solns. or short periods of radiation. At the beginning of the reaction, all the light is absorbed by the HI with decompn. of a portion of the mols. and formation of I ions; the latter then absorb light in proportion to their conc. (thus retarding the reaction) and the total intensity of light absorbed is not employed in decomposing HI. In order to test the law rigorously it is necessary

to calc. the absorbed light according to the relation $L_{\text{HI}} = L \frac{K_{\text{HI}} C_{\text{HI}}}{K_{\text{I}} C_{\text{I}} + K_{\text{HI}} C_{\text{HI}}}$ where

L is the total intensity of the absorbed light, L_{HI} is the intensity of the light absorbed by HI and C_{HI} and C_{I} are the concs. of HI and I, resp. The absorption of light by the soln. employed in the present instance is small and an error in the measurement of the distance from the source of radiation is committed if this distance is not measured with reference to the mean point of absorption in the liquid. The error in measurement of distance may be greatly reduced if a distance of approx. 2 m. instead of 20 cm. is employed and a source of light of great luminosity is used; diffused light would, however, play a greater role in this case.

Determination of the size of ultramicroscopic particles suspended in a liquid by a chrono-photometric method. G. REAUME. *Bull. soc. chim.* 17, 155-63(1915).—An app. has been arranged by which 10 exposures of a plate can be made, sepd. by known intervals of time, showing the positions of colloidal particles suspended in H_2O . The principle of the method is the same as that of Henri (C. A. 2, 2328). From the formula $D^2 = (RT/N)(l/3\pi\eta r)$ the projection of the trajectory of a particle may be used to compute the radius. D is the projection on the axis of observation during the time l , η is the viscosity of the medium, N Avogadro's number, and r the radius of the spherical particle. By using condensed solar light in the ultramicroscope it was possible to extend the observations to particles $6\mu\mu$ in radius. Plates were used, since a cinematograph film does not return to its original length after development. The expts. were made with a S colloid suspended in H_2O , using time intervals of 0.75 sec., at 20° . From 2 sets of expts. the values of displacements were found to be proportional to the radii of the particles.

The stability of some liquid films. P. PHILLIPS AND J. ROSE-INNES. *Proc. Phys. Soc. London* 27, 328-38(1915).—By use of elementary but rigorous math. the equilibrium form of a thin film which is a surface of revolution is calcd. The stability for certain kinds of displacement for the sphere, cylinder, and catenoid is considered. P. D. F.

The structure of the capillary layer. G. BAKKER. *Z. physik. Chem.* 90, 89-120 (1915); cf. C. A. 8, 1226; 9, 736.—The great disorder in the motion and position of the molecules makes it possible in the case of liquids, vapors and their transition layers to compensate the substance by a const. expanded agent. The potential function of the attractive forces between the elements of this agent is the function: $-fe^{r/\lambda}/r$, where λ is a very small distance and r the radius of the sphere of influence. It has been shown that λ is of the order of the mean distance between two liquid mols. If ϵ_1 , ϵ_2 , ϵ are the energy of the liquid, the vapor and the capillary layer (all per unit mass), then $[(\epsilon_1 + \epsilon_2)/2] - \epsilon = \Delta\epsilon$. If M represents the mol. wt., N Avogadro's number, and n the number of mol. layers in the capillary layer, then for those cases where the mol. wt. remains unchanged by vaporization, it is shown thermodynamically that $\Delta\epsilon/r_1 = \frac{1}{2} (\rho_1 - \rho_2)/(\rho_1 + \rho_2) - 1/\eta$ ($2\sqrt{\rho_1} + 2\sqrt{\rho_2}/(\rho_1 + \rho_2)$ $2\sqrt{N/M} [H - T \cdot (dH/d\epsilon)]/r_1$, where ρ_1 and ρ_2 represent the densities of liquid and vapor, and H and r_1 the surface tension and the internal heat of vaporization. In order to test the validity of this equation, the heat of vaporization of C_6H_6 has been calcd. at a number of different temps. At 80° , for example, $r = 40.4 \times 10^6$ ergs, a value which agrees closely with

that detd. exptly. by Brown. Similar calcns. have been made for ether. It has been shown that the number of mol. layers in the capillary layer is 3-4 at the m. p., and at a few degrees under the critical temp. is of the order of 12. Further it has been shown that the radius of the sphere of influence is equal to about 6-7 times the mean distance between the liquid mols.

H. JERMAIN CREIGHTON.

The influence of light on colloidal systems. H. STINTZING. *Kolloidchem. Beihefte* 6, 231-96(1914).—In the discussion of colloidal systems it was suggested that they be characterized according to their vol. dispersity. The various former expts. on the influence of light on colloidal systems were discussed. If a soln. of Ag resinate in benzene be exposed to partial illumination by means of a silhouet it is found that the Ag is deposited on the illuminated part. The conclusion reached is that the light causes an indirect chemical action. A thorough investigation was made, both qual. and quant., on the new phenomenon that if a colloidal system is partially exposed to light there is an increase in amount of substance in the illuminated section. This phenomenon is similar to photocrystn., photosublimation, photodromy and the increase in amt. of substance in gas systems on illuminated surfaces. Films on glass plates of moist gelatin containing water-sol. colored salts were exposed to light by covering them with a black lid in which slits had been cut; they showed after only a few min. a more intense color on the illuminated parts. This was noticed with all rays of light from ultra-red to ultra-violet. Partial heating also caused the same effect. It was found that there was a decided difference in temp. between the strips of gelatin exposed to light and the dark strips and that the illuminated strips evapd. more quickly than the dark ones. The increase in substance was due to partial evapn. and was toward the illuminated portion. A series of expts. was carried out to show this phenomenon quantitatively. The expts. (see original) were carried out so that the colloidal systems were exposed to strips of light (silhouets) in a thermostat in such a manner that the parts exposed and unexposed to light could be sepd. and analyzed quantitatively. Because of the simplicity of analysis the systems investigated were: Ag resinate in benzene; gelatin solns; ferrum dialysatum; and Ag sol (Bredig). It was found that the increase in substance in all cases was toward the illuminated parts. Qual. expts. were carried out with: gelatin solns. containing $\text{Co}(\text{NO}_3)_3$, NiSO_4 , KI, litmus, sugar and quinine sulfate; chlorophyll in water; eosin and fluorescein in alc.; picric acid and inorganic salts in glycerol; quinine sulfate in H_2SO_4 and dyestuffs in paraffin. The phenomenon of increase in substance toward the parts exposed to light was found to be typical for all colloidal systems and was not found in mol. disperse systems. The degree of increase in substance was about the same in the different colloidal systems, being about 20-30% of the total. The cause of the increase in substance was found to be due to evapn. of the solvent at the parts exposed to light, for where the possibility of evapn. was not present the phenomenon was not present.

W. F. ZIMMERLI.

The distribution law. G. v. GEORGEVICS. Prague. *Z. physik. Chem.* 90, 47-58(1915).—It is shown that abnormal distribution results may be due to other causes than association. Exam. of viscosity data shows that the chem. affinity of $\text{C}_6\text{H}_5\text{CO}_2\text{H}$ and $\text{CH}_3\text{CO}_2\text{H}$ for H_2O is great while that of HCO_2H is small. The distribution of these 3 substances between H_2O and C_6H_6 indicates association. It is shown, however, that the distribution completely corresponds to the process of sorption. Measurements have been made of the distribution of $\text{CH}_3\text{ClCO}_2\text{H}$ and $\text{CHCl}_2\text{CO}_2\text{H}$, also of pyridine, piperidine and hydrazine between H_2O and C_6H_6 (cf. *C. A.* 9, 2171). From the results of the investigation, it is concluded that characteristic α -values have the same importance for sorption as for the distribution of substances between C_6H_6 and H_2O ; and that the "distribution law" has, therefore, lost its value.

H. J. C.

An hypothesis concerning the condition of dissolved electrolytes. H. C. S.

SNETHLAGE. Univ. Groningen. *Z. physik. Chem.* **90**, 1-46(1915).—The hypothesis of Arrhenius is not applicable to solutions of electrolytes in MeOH and EtOH. There exist in these solvents two sharply separated groups of electrolytes. The first embraces the strong electrolytes such as HCl and the salts. The following properties of these solns. are proportional to the gross concn.: catalytic action, light absorption, and change of cond. by H₂O; while the law of Kohlrausch and cond. are simple functions of the concn. It is possible that the raising of the b. p. constitutes an exception. Therefore, the ratio Δ_9/Δ_∞ is of no small importance in the detn. of the typical electrolyte properties. The 2nd group, which embraces most of the organic acids and probably also bases, is differentiated from the 1st group in that such a proportionality does not exist. Solns. of electrolytes of the 2nd. group show increasing efficacy (calcd. per mol. dissolved substance) with decreasing concn. So far as cond. is concerned, this change is governed by Ostwald's dilution law, and the change of catalytic efficacy by the formula, $k_R = \{(\Delta_9/\Delta_\infty)k_A + (1-(\Delta_9/\Delta_\infty))k_N\}1/v$, where k_R is the velocity const. of the reaction, k_A the velocity attributed to unit concn. of the catalytic ion, k_N that for the undissociated mol. and v the concn. of the catalyst. These phenomena are explained by the hypothesis that the characteristic properties of these electrolytes do not proceed from the free ions, whose relative concn. changes with the concn. of electrolyte, but from a special property of the mol. of the dissolved substances which are elec. polar and thereby active, in contradistinction to the mols. of non-electrolytes. In the case of the 2nd group there exists an equil. which depends on the concn. between two kinds of mols.: active and inactive, the latter being few in number. For the cases investigated, the relative concn. of the two varieties is given approx. by the value of Δ_9/Δ_∞ . With reference to the electrolytic properties, cond., catalytic action, etc., the active mols. are practically identical with the mols. of the electrolytes of the 1st group. The dissociation const. determines the equil. between the active and inactive mols., and is highly dependent on the nature of the solvent. The change of the mol. cond. with concn. of electrolytes of the 1st group is the result of a mutual influencing of the mol. which may be either intra- or intermolecular. Correspondingly, the difference between Δ_∞ and the mol. cond. at any particular concn. is proportional to the mean sepn. of the mols. The value of Δ_∞ , which is reached when the concn. is so small that the "disturbing" influence ceases to be effective, is a measure of the elec. and the catalytic activity of the mol., and is governed by the electrochem. character of the ions. On the other hand, for electrolytes of the 2nd group the change in cond. results from the transition of inactive to active mols. In the cases investigated, the concn. of the active mols. is so small that the mutual influence is inappreciable. The value for Δ_∞ is attained when the vol. is so large that the mols. are all in the active condition. Evidence is put forward which shows that the explanation of the properties of the 1st group, on the supposition that dissociation into ions occurs, and that the degree of dissociation, independent of the concn., is 1, is incorrect. The activity of the mol. can be explained by ascribing to an electron a special position within the at., whereby the mol. has two poles. A splitting in the mol., in the sense of the dissociation hypothesis, does not occur. It is probable that the forces between these poles are closely associated with the affinity. At all events, they are a standard for the properties of the electrolyte. Solvation may also serve as measure of the elec. catalytic activity of the mol., for a larger value of Δ_∞ appears to be associated with a stronger catalytic action and a stronger solvation and vice versa. This holds probably for the active mols. of both groups. In the case of the 2nd group, the transition from inactive into active mols. appears to be a process which proceeds with participation of the solvent. This is very probable if it is assured that the resulting active mols. are solvated. In this event the reaction may be expressed: inactive mol. + solvent $\longrightarrow$ solvated active mol. It is pointed

out that, in alc. soln. for example, a K ion in KCl differs from a K ion in KNO₃. Both the investigation of catalytic phenomena and the consideration of properties in alc. soln. lead to a conception regarding the condition of the electrolyte in this solvent which differs considerably from that for aq. soln. In conclusion it is pointed out that the continuation of this problem is of great importance for the development of the theory of soln.

H. JERMAIN CREIGHTON.

Antimony pentachloride as solvent. E. MOLES. Madrid. *Z. physik. Chem.* 90, 70-88(1915).—Pure SbCl₅ melts at 3.0°. The value given in text books is false and refers to a product containing more than 5% Cl. Pure SbCl₅ is not colorless, as supposed, but lemon yellow. The cryoscopic const. $E = 18.5$. The heat of fusion of SbCl₅ is therefore 8.17 cal., $d_4^{20} = 2.3356$. The b. p. curve has been detd. between 9 and 90 mm. When dissolved in SbCl₅, Cl, Br, SnCl₄, SbCl₃, CrO₂Cl₂ and CrO₃ have a normal mol. wt.; ICl₃ and AuCl₃ are dissociated, and I, SnBr₄ and SnI₄ react with the solvent. Ebullioscopic expts. indicate that in CCl₄ and CHCl₃, at ordinary concns., SbCl₅ is normal, but in dil. solns. it is dissociated.

Electrolytic dissociation of acetylene and its metallic derivatives. M. SKOSS-AREWSKY. *J. chim. phys.* 13, 3-17(1915).—A more detailed discussion of the expts. described in C. A. 9, 543.

E. J. C.

Solubility influences. ERIK G. THORIN. Stockholm. *Z. physik. Chem.* 89, 685-92(1915).—Solns. of different salts in H₂O and in EtOH have been used as solvents. Measurements have been made of the lowering of the solubility produced by the different salts. It has been found that the solubility lowering, which different salts exert towards nonelectrolytes, varies considerably with the nature of the salt. For example, the action of the halogen salts of Na increases with their electro-affinity. A striking difference exists between the influence of aliphatic and aromatic anions. The aliphatic anions lower the solubility in the same manner and to the same degree as inorganic anions, while aromatic anions increase the solubility or influence it but slightly. The solvent itself is found to play a specific role in the change in solubility by salts.

H. JERMAIN CREIGHTON.

The velocity of the auto-esterification of dibasic acids. ANTON KAILAN. Vienna. *Z. physik. Chem.* 89, 641-75(1915).—The elec. cond. of oxalic, malonic, succinic, tartaric, fumaric and maleic acids at different concns. at 25° has been measured in abs. amyl alc., and in amyl alc. containing small and large amounts of H₂O. The order of the strengths of these acids in amyl alc. is different than in aq. soln., maleic acid having the greatest cond. The velocity of the auto-esterification of the above mentioned acids, as well as of malic acid, has been measured in amyl alc. at 25°. It has been found that the velocity does not correspond to the square of the concn., as is the case with monobasic acids, but is approx. proportional to the concn. raised to the $3/2$ power. Approx. calcn. shows that the reaction that is influenced by H ions participates in the total

reaction to a considerable extent, but that in the case of oxalic and maleic acids does not exceed 50-70%. It has been found that the value of the "sesquimolecular" const. does not increase with increasing acid concn. as would be expected. This is explained by assuming that, in addition to the two reactions which occur in the case of auto-esterification with monobasic acids, here a 3rd reaction between an acid mol. and the alc. takes place. The one carboxyl group of a dibasic acid can consequently influence the auto-esterification of its own mol. as well as the auto-esterification of the carboxyl group of another mol. It has been found that the relative catalytic action of the undissociated acid mols. increases with increasing acid strength. This rule appears to hold for the above mentioned 3rd reaction. The retarding influence of the H_2O is usually very small, but differs from case to case. The order of the velocities of the auto-esterification of the acids investigated is not the same as in the case of esterification with alc. HCl. Evidence is put forward which indicates that steric influences play a part in indirect, as well as direct, ester formation. H. JERMAIN CREIGHTON.

Indirect ester formation in alcohol-water mixtures. ANTON KAILAN. Vienna. *Z. physik. Chem.* 89, 676-84(1915); cf. preceding abstr.—Measurements have been made of the velocity of esterification of succinic acid in alc.- H_2O mixts., which contain 12.3, 25, 50 and 75 vol. % of H_2O . In these expts. HCl has been used as a catalyst. Detns. of the cond. of HCl in the different mixts. have also been carried out. It has been found that the esterification of succinic acid, with $N/6$ HCl as catalyst, in an alc.- H_2O mixt. that contains 25 volume per cent H_2O is 100 times slower than in an alc.- C_2H_5 mixt. of the same alc. content; while with 50 volume per cent H_2O the esterification is 150 times slower than in the corresponding alc.- C_2H_5 mixt. H. J. C.

Catalysis. XXI. Reactions of both the ions and the molecules of acids, bases and salts. Reactions of sodium ethylate with methyl iodide in absolute ethyl alcohol at 25°. H. C. ROBERTSON, JR. AND S. F. ACREE. *J. Am. Chem. Soc.* 37, 1902-9(1915); cf. *C. A.* 7, 3125; 9, 544, 2018.—Using the method described in earlier papers, R. and A. have detd. the velocity of reaction at 25° between 0.5-0.025 N NaOEt and 0.5-0.125 N MeI in EtOH, also in EtOH with 1% H_2O , EtOH with 10% Et_2O , and in the presence of 0.5-1.0 equiv. NaI. In agreement with the earlier work, it is found that the reaction is not purely ionic, the "deviation" being strictly proportional to the concn. of the non-ionized NaOEt. The values K_i (0.127) and K_m (0.0596) agree well with those previously found for MeI and KOEt (0.126 and 0.0687) and for MeI and LiOEt (0.1367 and 0.03871) (according to the theory the K_i values should be identical). The addition of considerable amts. of Et_2O and NaI to some mixts. shows that the small amts. of these formed during the time periods measured in the other mixts. have no great effect on the reaction velocities. In a table in which the observed K_N values have been corrected for an assumed positive "salt catalysis" of 8% per g. mol. NaOEt K_i is raised from 0.127 to 0.136 and K_m lowered from 0.0594 to 0.05538. The harmony of the present work with that on KOEt and LiOEt shows that the "salt effect," whether large or small, is nearly the same for the 3 ethylates. **XXII. Reinterpretation of the reactions of sodium methylate and sodium ethylate with 1,2-dinitrobenzene, 1,2,4-dinitrochlorobenzene and 1,2,4-dinitrobenzene.** S. F. ACREE. *Ibid* 1909-14.—The work of Bruyn, Steger and Lulofs (*Z. physik. Chem.* 49, 329 et seq.(1904); *Rec. trav. chim.* 18, 13, 41; 20, 292) has been recalcd. on the assumption that the reactions are both ionic and mol.; the ionization of the NaOEt was obtained from A.'s own data, that of the NaOMe calcd. from Tijmstra Bz's (*Z. physik. Chem.* 49, 349(1904)). The values for K_N thus found agree closely with B., S. and L.'s observed reaction velocities. The following are the values obtained for K_i and K_m , resp.: NaOEt and o - $C_6H_4(NO_2)_2$ in EtOH at 45°, 0.229, 0.230; NaOMe and o - $C_6H_4(NO_2)_2$ in MeOH at 45°, 0.1458, 0.1278; NaOMe and 3,4-(ON_2) $_2$ C_6H_3Cl in 90.3% MeOH at 15°, 1.376, 0.759; NaOMe and 3,4-

$(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Cl}$ in abs. MeOH at 15° , 1.299, 0.724; NaOEt and 3,4- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Br}$ in EtOH at 15° , 2.838, 0.823; NaOEt and 3,4- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Cl}$ in EtOH at 15° , 4.473, 1.195. Since the ions and mols. of NaOEt react with the same velocity with $o\text{-C}_6\text{H}_4(\text{NO}_2)_2$, the addition of NaNO_2 and NaOAc should not affect the reaction velocity, a deduction confirmed by expt., while on the other hand, in conformity with the theory, the addition of NaI to NaOEt and 3,4- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Br}$ lowers the reaction velocity. C. A. R.

Catalytic effect of metals and metallic compounds. H. J. PRINS. Zaandam. *Chem. Weekblad* 12, 588-92(1915).—An address dealing with the "activation" theory of catalysis (cf. C. A. 8, 2695). GEORGE W. MOREY.

Speed of reduction of potassium permanganate by oxalic acid. A. BOUTARIC. *Compt. rend.* 160, 711-4(1915).—The amt. of unchanged KMnO_4 in soln. at a given time has been detd. by the intensity of a radiation of certain wave length after passing through the soln. If I_0 is the intensity transmitted when the concn. of KMnO_4 is zero, I_a that for a quantity a , the amt. of KMnO_4 changed at the end of a time t is x in the equations $I = I_0 e^{-hx}$, $I_a = I_0 e^{-ha}$, where the const. h depends on the radiation used ($\lambda 558\mu$ in these expts.) and on the thickness of the layer of soln. The velocity of the reaction was not, for the most part, proportional to the concn. of KMnO_4 ; it started at zero, increased to a max., and then decreased again. A "logarithmic law" was not followed. Details of the expts. are to be published later. E. B. M.

The specific heat and heat of fusion of ice. H. C. DICKINSON AND N. S. OSBORNE. *J. Wash. Acad.* 5, 338-46(1915); *Bur. Standards Sci. paper* 248; *Am. Soc. Refrigerating Engineers* 1, 32-61(1915).—Besides their value as natural consts., the results of this paper have a very important bearing on the molecular nature of the change of state solid-liquid. The detns. were made with the "aneroid" calorimeter (C. A. 9, 1705), which permitted detns. (1) of very high accuracy, (2) for very small temp. intervals (0.03° in one case), (3) on samples of water which were kept pure and invariable by hermetical sealing in a tin-lined case. Several writers had observed that the sp. heat of ice increased rapidly just below the m. p., and Nernst and many others had considered that it really increased in accordance with the observations. A. W. Smith (1903) found that the effect diminished as the ice became purer. He suggested that it was probably due to the slight melting caused by impurity, and would be absent in perfectly pure ice. This suggestion is strongly confirmed by the present results. Extraordinary precautions were taken in the purification of the samples, and the apparent increase in the specific heat is far less than that obtained by previous observers. Assuming that the lowering of the freezing point of the ice is proportional to the amount of dissolved impurity, D. and O. find that the apparent increase in the sp. heat, resulting from partial melting, is practically $19.75 \text{ } l/\theta^3$ where θ is temp. measured downward from zero, and l is the lowering of the m. p. owing to the impurity—that is, the temp. (below the zero for pure ice) at which the last of the sample melts. The results followed this formula within the exptl. errors. l , the final lowering, was calcd. to be about 0.001° in 3 samples, only 0.0005° in another still more carefully prepd. one, but no direct detn. of the actual difference in m. p. of the two was attempted. Cond. measurements, also, indicated less impurity than was needed to account for the variation in the sp. heat. It will, of course, always be impossible to show that there is no variation of sp. heat just before melting, because the exptl. difficulties increase indefinitely as the interval below m. p. decreases, but the results with the authors' 4th sample appear to show that the variations actually encountered in the other 3, redistilled and boiled, samples were due to impurity. Much more, therefore, do the results show that the greater variations observed by previous workers were due to impurity. All positive evidence of special variation in the specific heat near the m. p. appears, therefore, to be contradicted. It follows also that for the ice used by previous observers, and sup-

posed to be specially pure, the m. p. must have been appreciably more than 0.001° below that of pure ice—an interesting result which D. and O. do not discuss. The authors' formula for the sp. heat of ice from 0° to -40° is: $S = 0.5057 + 0.001863 \theta - 79.75 (1/\theta^2)$, where the first two terms are probably sufficient for absolutely pure ice. The latent heat (3 detns.) was found to be 79.76, with a discrepancy of about 0.002. The mean of this and a previous series of detns. by another method is 79.75.

W. P. WHITE.

The change in thermal conductivity of metals on fusion. ALFRED W. PORTER AND F. SIMMON. London. *Proc. Phys. Soc. London* 27, 307-14 (1915).—Cylinders of Hg and Na in glass tubes were heated at the top and so cooled at the bottom that half the metal was liquid and half solid, and the temp. distribution along the axis obtained by thermocouples inserted in narrow tubular depressions formed in the glass wall by locally heating and forcing in a knitting needle. The ratio of the thermal cond. for solid and liquid states, K_s/K_l , equals the ratio of the slopes of the temp. vs. distance along tube curve on each side of the m. p. $K_s/K_l = 3.91$ for Hg and 1.31 for Na.

PAUL D. FOOTE.

The thermal conductivity of mercury by the impressed velocity method. H. R. NETTLETON. Birkbeck Coll. *Proc. Phys. Soc. London* 26, 28-40 (1914). Discussion. *Ibid* 40-2.—Hg was passed through a vertical tube which was heated at the top and maintained at 0° at the bottom. The temp. distribution in the tube was obtained by a thermocouple; this data permits the detn. of the thermal cond. A mean value of 0.0201 c. g. s. units at 15.5° was obtained.

PAUL D. FOOTE.

The vacuum guard ring and its application to the determination of the thermal conductivity of mercury. H. R. NETTLETON. *Proc. Phys. Soc. London* 27, 129-48 (1915).—A vacuum cylindrical vessel containing Hg was maintained at its ends at 2 different const. temps. The vacuum chamber on the sides acts as a guard ring mitigating heat loss radially. Temp. distribution was obtained by exploration with a thermocouple and heat flow along the Hg column was measured by a spiral coil through which water flowed at a measured inlet and outlet temp. The mean value of thermal cond. of Hg was found to be 0.0196 c. g. s. units over a range 35 to 45° . From 30 to 50° it is practically const., possibly increasing slightly with increasing temp.

PAUL D. FOOTE.

Thermal and electrical conductivities of some of the rarer metals and alloys. THOMAS BARRATT. Wandsworth Tech. Inst. *Proc. Phys. Soc. London* 26, 347-70 (1914).—A new method of the "stationary temp." type was employed for detg. the thermal conds., k , from 20 to 100° , of Pt, Ir, Pt-Ir alloys, 90 Pt-10 Rh alloy, Rh, Au, constantan, W, Pd, Ta, and graphite. Elec. conds. K were also measured and values of k/KT computed where T = abs. temp. In general these values for pure metals range about 2.5×10^{-8} , though W, Rh, and Ir differ considerably from 2.5, giving about 3.9, 1.4, and 1.7, respectively. Graphite is also a very pronounced exception for its thermal cond. is very nearly that of 80 Pt-20 Ir, while its elec. cond. is 600 times less. k/KT for graphite ranges from 1110 to 770. Data on Pt-Ir alloys afford a good example of the effect of impurities on thermal and elec. properties of a metal. Grüneisen showed that the addition of a small amt. of impurity reduces the elec. cond. more than the thermal cond. Up to 90 Pt-10 Ir this property holds, but for higher amts. of Ir the thermal cond. decreases more rapidly than the elec. In general (Pt excepted) the thermal cond. decreases with increasing temp. In the temp. range employed, however, the slight observed temp. coeff. of thermal cond. might be ascribed to exptl. errors.

PAUL D. FOOTE.

Thermal conductivity. II. Thermal conductivity of badly conducting solids. THOMAS BARRATT. *Proc. Phys. Soc. London* 27, 81-92 (1915). Discussion. *Ibid*

92-3. The above method was employed for detg. the thermal conds. from 20 to 100° of fused silica, soda glass, red fiber, fire brick, ebônite, gas carbon, mahogany, walnut, oak, lignum vitae, greenheart, Am. whitewood, and boxwood. The woods show large temp. coeffs. of thermal cond. but possibly heating at 100° alters the structure.

PAUL D. FOOTE.

Specific heat of platinum at elevated temperatures. LUIGINA FABARO. Rome. *Nuovo cimento* 9, 123-39(1915).—By a thermo-elec. method, F. confirms the fact that the sp. heat of Pt at const. vol., even for high temps., increases with the temp., contrary to the general theory according to which the sp. heat is const. at such temps. S. L.

Equilibrium in the system: water, phenol and benzene. S. HORIBA. *Mem. Coll. Sci. Kyoto* 1, 49-55(1914).—The equil. relations in this ternary system have been examd. at 25°. The phenol in the solns. was detd. by means of Br, and the C_6H_6 and

H_2O by measuring the quantities of each which were necessary for the production of permanent turbidity. The results are shown in the following table and also in the triangular graph:

MIXTS. WITH 2 LAYERS.

Upper layer.			Lower layer.		
Phenol. Per cent.	Benzene. Per cent.	Water. Per cent.	Phenol. Per cent.	Benzene. Per cent.	Water. Per cent.
0	99.95	0.05	0	0.198	99.802
4.78	94.98	0.24	1.43	0.21	98.36
17.36	81.83	0.81	2.80	0.21	96.99
21.15	77.22	1.63	3.01	0.21	96.77
28.01	69.81	2.18	3.35	0.21	96.44
44.39	50.56	5.05	4.07	0.19	95.74
55.80	36.13	8.07	4.58	0.19	95.23
74.5	3.0	22.5	5.65	0.17	94.18
70.71	0	29.29	8.195	0	91.805

Satd. solns. with phenol as solid residue were found to have the following compn.:
 (1) 81.06% PhOH, 18.94% C_6H_6 , 0% H_2O ; 89.78 PhOH, 7.92 C_6H_6 , 2.30% H_2O ; 92.31 PhOH, 4.07 C_6H_6 , 3.62% H_2O ; 95.14 PhOH, 0 C_6H_6 , 4.86% H_2O . E. J. C.

Equilibria in ternary systems. XVIII. F. A. H. SCHREINEMAKERS. *Proc. Akad. Wetenschappen* 17, 1260-74(1915).—S. derives formulas and outlines conditions of vapor-pressure and sublimation curves in certain equilibria. B. R.

E. B. MILLARD.

The Thomson effects in tungsten, tantalum and carbon at incandescent temperatures determined by an optical pyrometer method. A. G. WORTHING. Nela Lab. *Phys. Rev.* 5, 445-51(1915).—A method is given for detg. the Thomson effect in filaments of incandescent lamps by means of a temp. survey near a cooling junction, with a Holborn Kurlbaum pyrometer. The temp. distribution depends upon whether a. c. or d. c. is used in heating and upon the direction of d. c. Factors requiring consideration are: rate of development of heat in an element of the filament, radiation intensity, distance along and radius of filament, heating capacity, resistivity, temp., rate of heat conduction, thermal cond., and several important consts., yet in spite of these many variables, surprising accuracy is obtainable. The following values of the Thomson e. m. f. coeffs., microvolts per degree, (σ), were observed: (1) temp. abs., (2) σ . W 2200, —35; 2000, —28; 1800, —21 to —16; 1600, —11; 1500, —10; Ta 2100, +24; 1900, +20; 1700, +16; C 2100, —22; 2000, —21; 1800, —19.

PAUL D. FOOTE.

High temperature investigation and a study of metallic conduction. EDWIN F. NORTHRUP. Princeton. *J. Frank. Inst.* 179, 621-62(1915).—The Drude electron theory of metallic conduction is rejected and a new theory of "electronic transfer" is developed, which agrees approx. qual. with expt. The mols. are assumed to be perfect conductors in oscillation, and attached to the surface of each mol. are a number of electrons. When there is no elec. stress each mol. is electrically neutral. Suppose an elec. stress is impressed in a given direction. This drives all the electrons to one side of the mol. to which they are attached, say, to the right side. The mol. in oscillating comes in contact with another mol. on the right and immediately gives up its electrons to the left side of the new mol. The electrons then slide about this mol. to the right side and the process is repeated with a final transfer of electrons from left to right. The theory, with reasons for the mol. and electronic movements, is developed in math. detail which does not permit abstracting.

Deposition from flames by electricity and experiments to determine the validity of Faraday's law for flame conduction. BRUNO THIEME. Berlin. *Z. physik. Chem.* 89, 693-727(1915).—Expts. carried out with C at high temps. show that the Faraday law for the electrolytic sepn. of C from flame gases is substantiated, provided at these temps. the C is monovalent.

H. JERMAIN CREIGHTON.

Electro-optics of the hydrogen molecule. A. HEYDWEILER. *Verh. deut. physik. Ges.* 16, 179-88(1915).—H. finds a good agreement between the calcd. and observed values for refraction, magnetic rotation and dispersion of light by gaseous H. This gives a satisfactory confirmation of Drude's electron theory if it is assumed that in a mol. there is a slowly vibrating valence electron and a not accurately detd. number of bound electrons vibrating more rapidly. The vibration frequency of the first may safely be taken as $\nu_1 = 3.14 \times 10^{15}$ sec.⁻¹ (accurate to within 1% or less); that of the 2nd kind of electrons differs according to the number which are assumed to be present. If the number is 3, the frequency is $\nu_2 = 11.3 \times 10^{15}$ sec.⁻¹. The accuracy of this value is less than that of the first.

E. B. MILLARD.

The emissivity of metals and oxides. III. The total emissivity of platinum and the relation between total emissivity and resistivity. PAUL D. FOOTE. *Bur. Standards, Sci. Paper No. 243*, 6 pp.(1915); see *C. A.* 9, 404. **IV. Iron oxide.** GEORGE K. BURGESS AND PAUL D. FOOTE. *Bur. Standards, Sci. Paper No. 249*, 7 pp.(1915); *J. Wash. Acad.* 5, 377-8(1915).—The total and monochromatic emissivity of the oxide surface formed upon Fe heated in air was detd. by use of radiation and optical pyrometers. For observed temps. of 600, 700, etc., to 1100°, (a) by optical pyrometer and (b) by radiation pyrometer, the following are true temps.: (a) 600, 700, 801, 902, 1004, 1106, and (b) 630, 735, 835, 940, 1040, 1145. A large temp. drop exists through the oxide layer; this appears to be of approx. the same order of magnitude for different sized samples from iron tubes to 100 lb. rails, and increases rapidly with temp., rising from 10° at 600° to about 100° at outside temp. of 1100°. Thus, to obtain the temp. of the Fe under the oxide the pyrometer reading must be corrected for lack of blackness of the oxide and for temp. gradient throughout the oxide. PAUL D. FOOTE.

Influence of structure-action, especially the Thomson constructive force, on the electron emission of metals. W. SCHOTTKY. *Physik. Z.* 15, 872-8(1914); cf. *C. A.* 8, 2842, 3147, 3746. E. B. MILLARD.

Pure electron discharge. S. G. BROWN. *Electrician* 75, 323(1915).—Polemical against Irving Langmuir (cf. *C. A.* 9, 2036). Priority is discussed. S. E.

Hall and Corbino effects. E. P. ADAMS. *Proc. Am. Phil. Soc.* 53, 47-51(1915); cf. *Phil. Mag.* 27, 244(1914); *C. A.* 9, 1576.—The Corbino effect has to do with the production of a secondary circular current in a metallic disk when a primary radial current is sent through it, and the disk is placed in a magnetic field perpendicular to its plane. (Cf. *Physik. Z.* 12, 561, 842(1911).) Some calcns. have been made to show that this effect and the Hall effect are essentially the same, and that any explanation of one effect will explain the other. The Corbino effect is easier to measure, since it is not necessary to use very thin films and there are no free transverse boundaries. E. B. M.

Ozonization of liquid oxygen by radiation. E. WARBURG. *Verh. deut. physik. Ges.* 17, 194-7(1915).—Liquid O or liquid air was employed in place of the gases at high pressures in the usual ozone app. It showed the same absorption as that ascribed to compressed O by Liveing and Dewar (*Proc. Roy. Soc. London* 46, 222(1890)). Since liquid O obeys Trouton's rule, it is not much polymerized, and the increased absorption must be due to mol. collisions. The Zn arc spectrum passed through the empty quartz app. from λ 203 to 332 μ to a considerable extent, but was completely absorbed up to 256 μ by liquid air and up to 261 μ by liquid O. O₂ was shown to be present in the gas rising from the tube contg. the liquid air or O. Its presence in the liquid was also shown by the disappearance of the line groups 0.277 to 0.280 μ from the transmitted spectrum shortly after the radiations fell upon the liquid, and later the spectrum to 0.29 μ was either weakened or totally absorbed. E. B. MILLARD.

The spectra of some metallic compounds. G. TAMMANN. *Göttingen. Z. anorg. allgem. Chem.* 92, 76-80(1915).—A comparison of the arc spectra of some metallic compds. with those of their components, in order to obtain evidence as to the constitution of the compds. The spectra of Cu₃Sb and Zn₃Cu₂ were the sum of the spectra of their components. The spectra obtained with a Mg alloy containing 30% Sb, with Bi₂Mg₃, and with Mg₂Sn were characterized by the reversal of the Mg line 285.2, but otherwise were identical with the spectra of the components, though a few lines may have been missing. GEORGE W. MOREY.

The ultraviolet absorption of several mono derivatives of benzene. CHRISTINE STRASSER. *Z. wiss. Phot.* 14, 282-311(1915).—The ultraviolet absorption spectra of the following substances were measured from λ 2900 to 2300, and a theoretical dis-

cussion of the results is given: C_6H_5F , C_6H_5CHO , C_6H_5CN , $C_6H_5CH_2OH$, $C_6H_5CH_2OC_2H_5$ and C_6H_5COOH . C_6H_5F and C_6H_5CN especially have a multitude of fine absorption lines. The absorption lines of all the compds. are correlated in series: a grouping of pairs in which the distance between adjacent pairs is called the long difference and between two lines of the same pair the short difference. In the following table showing the relation between chem. constitution and spectra the 1st row gives the material, 2nd row long differences and 3rd row short differences, expressed in frequencies:

F.	Cl.	CH ₃ .	Br.	COOH.	NH ₂ .	OCH ₃ .	COH.	CN.	CH ₂ OH.
97.0	96.5	96.3	95.8	95.7	95.4	95.3	95.3	94.0	94.0
5.0	3.3	3.1	2.8	?	15.7	19.8	15.3	23.6	?

94.0	94.0	92.2							
?	15.2	..							

PAUL D. FOOTR.

Use of a rotating sector in photographic photometry. A. E. WEBER. *Ann. Physik* 45, 801-38(1914).—Expts. have been made on 6 kinds of plates, each suited to some particular purpose. The source of light was photographed for a given length of time. Then a group of lines was photographed on the same plate, using a light source of the same wave length and of const. intensity, for another length of time. In the first exposure a sector opening of 360° was used, and in the succeeding ones the sector opening was made smaller and smaller. After development, the amount of blackening from the source under investigation was compared with that from the group of lines in an illumination of known intensity for a known time, and the unknown intensity detd. by interpolation. The detns. could also be made with a rotating sector having 2 openings, the ratio of light to pause then bearing a definite relation to the angle of opening. For $\lambda = 434.8 \mu\mu$, the values detd. were independent of the speed of rotation of the sector, between 120 and 1890 r. p. m., and of the time of exposure, if it was between 15 and 300 sec. Since the intensity was also independent of the type of plate used, the method was suited to ultraviolet photometry. The method was not suited to expts. with weak light sources, since then long periods of exposure were required. Expts. were made with $\lambda\lambda$ 334.2, 248.2, 434.8, 546, 577.9 and $650 \mu\mu$. The errors were generally within $\pm 4\%$, part of which was due to variations in the plates, and most of the remainder to errors in the blackening comparisons.

Experiments on condensation nuclei produced in gases by ultraviolet light. MAUD SALT MARSH. Bedford Coll. *Proc. Phys. Soc. London* 27, 357-69(1915). Discussion. 369-70.—From exptl. investigation with gases and vapors in a Wilson expansion app. the following conclusions were drawn: Nuclei produced in air by ultraviolet light which has traversed a few cm. of air are not affected by an elec. field of 50 volts per cm. The nuclei are equally effective in producing condensation of water, toluene and turpentine vapors, and they are formed even by light which has traversed 50 cm. air. Alc. vapor condenses without expansion on much smaller nuclei than water. No nuclei were formed by light in absence of O or CO₂. There was no trace of H₂O₂ in the clouds on nuclei. O containing ozone also contains nuclei for condensation having similar properties to those formed by ultraviolet light. The nuclei can be destroyed by heating. It seems probable that the nuclei formed by ultraviolet light do not cause condensation by virtue of any particular chem. compound but that they are particles large enough to act like dust particles as centers round which condensation can begin. P. D. F.

Vapor pressures of ethane and ethylene at temperatures below their normal boiling points. G. A. BURRELL AND I. W. ROBERTSON. *J. Am. Chem. Soc.* 37, 1893-902(1915).—The satd. vapor pressure of C_2H_6 has been found to range from 760 mm. at -89.3° to 1 mm. at -159.8° ; that of C_2H_4 from 760 mm. at -103.9° to 4 mm. at -159.9° . The app. used is described in detail. C. A. ROUITLER.

The spectrum of homogeneous secondary X-rays. M. GLAGOLEV. *Compt. rend.* 160, 709-10(1915).—In making a study of the reflection of secondary X-rays, the primary rays emitted by the Pt anticathode of a large Röntgen tube were allowed to fall on a Cu plate placed before the window of a Pb chamber. In the chamber behind the window was mounted a crystal of NaCl and a photographic plate suitably orientated. After an exposure of 12 hrs. there was obtained on the photographic plate in the region of incidence of the rays reflected by the crystal at different angles, a line clearly defined and a second line less distinct. No trace of a continuous spectrum was visible. It was concluded that in the spectrum of the secondary rays emitted by Cu the line spectrum is much more pronounced than the continuous spectrum, and that the secondary rays undergo reflection from a crystal surface only at certain well-defined angles. The wave lengths of the rays reflected from Cu were detd. accurately to within 6%. Within these limits the wave lengths obtained are identical with those given by Moseley for the α and β lines of Cu. W. H. ROSS.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Preparation, properties and composition of silundum. S. A. TUCKER AND A. LOWY. Col. Univ. *J. Ind. Eng. Chem.* 7, 565-71(1915).—Two varieties of silundum are formed, a slate-green, which has the formula Si_4C_4O and a gray, corresponding to the formula SiC . The temp. of formation lies above 1300° , the first variety (slate-green)

being formed up to about 1800° while above this point SiC is formed. Continued heating above 2200° results in the decompn. of silundum with the formation of graphite. The extent of penetration of silundum in the charge depends upon the duration of heating, the process being more complete when the object is embedded in the charge. Silundum is a good conductor of electricity with a negative temp. coeff. for its resistance, possesses a hardness of about 9 (Mohr scale), a sp. gr. of 2.9-3, is not attacked by H, O or N (even at 1100°) or acids. It is attacked by some fused salts such as Na_2CO_3 , NaOH, KOH. T. and L. have developed a new method for detg. C in such materials based on combustion (in electric furnace) in presence of PbO in a current of O. The method is accurate to 0.3% of theoretical.

ISADOR MILLER.

Preparation of aluminium from Russian minerals. N. PUSHIN, É. DISHLER AND M. MAKSIMENKO. *J. Russ. Phys. Chem. Soc.* 46, 1347-65 (1914).—Since no Al has so far been manufactured in Russia, the authors worked out a method for obtaining it from Russian minerals. The method is as follows: Russian soimonite (63% Al_2O_3) is converted into Na aluminate by calcination with Na_2CO_3 , the product is dissolved in H_2O , the soln. filtered, and the hot filtrate satd. with CO_2 which ppts. Al_2O_3 in cryst. form. By carefully treating part of the Al_2O_3 thus obtained with a definite amt. of HF it is converted into basic Al_2OF_6 , and the latter, when mixed with NaF, gives artificial cryolite. To this is added the other part of the Al_2O_3 , and the mixt. electrolyzed. With a proper adjustment of c. d. and keeping the conc. of Al_2O_3 at about 40 mol. % by adding from time to time either Al_2O_3 or Al_2OF_6 , the yield of Al is as satisfactory as in the large factories.

H. M. GORDIN.

Electrolytic copper refining. FRANZ ALTNER. *Metall u. Erz* 3, 173-8 (1915).—A process is described applicable to either Pb or Cu refining. The series process is used and in general the operations are similar to those of the Hayden process, but in this case one side of the electrode is coated with vaseline or paraffin, which makes it possible to strip off the deposited material whenever it has attained the desired thickness. It is not necessary to roll the electrodes as in the Hayden process. C. R. H.

Anodic solution of lead. N. M. BELL. *Trans. Faraday Soc.* May 11, 1915 (12 pp.) (*advance proof*).—By electrolyzing $\text{Pb}(\text{OAc})_2$, NaOAc, KH tartrate, H_2SiF_6 , KBr and $\text{Na}_2\text{S}_2\text{O}_8$ with a Pb anode and using several c. ds., it was found that the anode lost more Pb than it should from Faraday's law for divalent ions. In the case of 4 of the solns., $\text{Pb}(\text{OAc})_2$, $\text{KHC}_4\text{H}_4\text{O}_6$, H_2SiF_6 and KBr, it was shown from a blank treated in the same way as the anode but not electrolyzed, that the extra loss was due to chem. soln. and mechanical detachment in cleaning. In the cases of NaOAc and $\text{Na}_2\text{S}_2\text{O}_8$, (particularly the latter), such an explanation would not seem readily applicable, and the loss was taken as evidence of the formation of monovalent Pb ions. If such were the case, these ions were 2.8% of all those formed in the NaOAc and 5.6% of those in the $\text{Na}_2\text{S}_2\text{O}_8$ soln. A black deposit on the anode in the latter soln. may have been a mono-Pb compd., or PbS, or finely divided Pb due to breaking up of a mono-compd. with the formation of Pb or due to the Pb dissolving anodically in only one direction. Further work is to be done.

Brit., 6,865, Mar. 18, 1914. F. W. HIGHFIELD. **Molten zinc** is obtained from oxide or blue powder by feeding the material directly on a bed of C heated elec. to about 1050° in an atm. of pure CO, air being excluded; the molten metal percolates through the C and collects and passes into a cooling-chamber containing a neutral or reducing atm., such as N or the residue from the air present at starting.

Brit., 6,866, Mar. 18, 1914. F. W. HIGHFIELD. In the reduction of complex sulfide ores, the ore is first roasted and thereafter a reducing-atm. is formed in the furnace, and the charge is heated elec. to obtain metal and mat. The Pb is run off and cupelled, preferably in an elec. heated hearth, and the residual mat is further heated by means of a direct current. Cf. C. A. 9, 2220.

Brit., 6,993, Mar. 19, 1914. ELEKTRO-OSMOSE AKT.-GES. Peat or other organic or inorganic material is subdivided as finely as possible, in a ball mill, *e. g.*, to facilitate subsequent removal of H_2O or juice by elec. endosmose. An electrolyte such as NaOH soln. may be added in amt. proportional to the fineness obtained. This addition is preferably made before comminution, which is assisted thereby.

Brit., 6,995, Mar. 19, 1914. ELEKTRO-OSMOSE AKT.-GES. In electric endosmose, a colloid is added with or before an electrolyte to a mass being ground in accordance with the process described in 6,993, 1914 (*supra*). The beneficial effect of the electrolyte during subsequent extn. of H_2O by elec. endosmose is thus enhanced. Suitable colloids are silicic acid and humic substances such as Cassel brown. In the treatment of steatite, Na_2SiO_3 may be added, to furnish (by dissociation) both the electrolyte and the colloid.

Brit., 29,418, Dec. 20, 1913. SODIUM PROCESS CO. In an electrolytic furnace a cathode, applicable to the production of light metals such as Na from salts such as chlorides, comprizes an inner part and a surrounding sleeve connected to it at 1 end only. Current flows in opposite directions in the inner and outer parts of the cathode, so as to lessen electrodynamic effects on the electrolyte. In the furnace shown, the cathode *c* is hollow and enters from below, and the metal sleeve *k* is insulated from it, except at the top, by asbestos. A pool of Na or other metal, confined by a salt-encrusted cooling-coil *d*, floats in contact with the cathode, and the excess of metal escapes through the cathode, into which a short tube projects for this purpose. C anodes *b* supplied with current by C rods *b'* wholly or partly surround the cathode and cooling-coil.

Ger., 283,068, Dec. 4, 1913. CHEM. FABRIK VON HEYDEN AKT.-GHS. A depolarizer for galvanic elements with NH_4Cl in the electrolyte consists of manganomanganites or other manganites whose liberated bases do not decompose NH_4Cl . The depolarizing masses used heretofore for galvanic elements, wherein artificial instead of natural MnO_2 has been used, occasion loss of NH_4Cl , inasmuch as during the action of the element the liberated Mn base reacts with the NH_4Cl of the electrolyte with the evolution of NH_3 . This objection is met in the selection of manganites, whose base consists wholly or in part of MnO or of an oxide approaching it, instead of the heretofore used alkali- or Ca-manganites. These manganomanganites are prepared from the com. alkali- or Ca-manganites, which are treated with sol. manganous salts.

Ger., 283,110, Mar. 20, 1912. SPEZIALFABRIK FÜR ALUMINIUM-SPULEN UND LEITUNGEN, G. M. B. H. In the electrolytic insulation of aluminium wire, and the like, whereby the wire is constituted as the anode in a bath of alkali silicates, and subjected to high tension electrolysis, substances (as NaCl) are added to the electrolytic bath which are adapted to reducing the max. polarization tension of the Al or the like. Furthermore, substances giving off O (such as H_2O_2) are added to the bath, in order to harden the insulating layer by increasing the O content. Consequently, the tension required in the process is lessened, and there is no danger that the wire may melt.

Ger., 283,276, May 25, 1913. BOSNISCHE ELEKTRIZITÄTS-AKT.-GHS. In the manuf. of calcium carbide, in continuous process, by the fusion of lime and coal in the elec. furnace, the C electrodes take part in the reduction of the CaO and are consumed, the more rapidly as they come in contact with CaO . To avoid this, the electrodes are imbedded in a mixt. of CaO and coal which is poor in CaO , and then a lime-rich mixt. is added as the charge.

Ger., 283,285, Sept. 20, 1913. ELEKTRO-OSMOSE AKT.-GHS. (GRAF SCHWERIN GHS.). In tanning, impregnating and like processes, the liquid containing the active substances and in which the material under treatment is immersed, is subjected to the action of the elec. current between diaphragms, maintaining circulation of the liquid by means of stirrers, or the like. The charge at the diaphragms is detd. so that the substances subject to electroösmose pass through, while the active substances are retained.

Ger., 283,484, May 20, 1913. ALLGEMEINE ELEKTRIZITÄTS-GHS. In a high pressure mercury vapor lamp, the entire space in which the condensation of Hg may occur, is filled with substances which do not affect the action of the lamp, in order to increase the pressure and, therefore, the candle power. Quartz pearls are specified. Cf. C. A. 8, 3273.

Swed., 36,626, Jan. 16, 1913. K. U. O. LÖBECK. In the manuf. of a mass composed of the higher O-compds. of Ni, for use as positive electrodes of alkaline accumulators, the higher oxides of Ni are reduced to a lower state of oxidation with a reducing liquid or a gas, and mixed with solid pulverulent substances which in contact with a liquid yield a reducing liquid or a reducing gas. Such compds. are, *e. g.*, sugar or a metal, such as Zn or Al, which dissolves in alkali with the evolution of H_2 . This latter effects the desired reduction.

5. PHOTOGRAPHY.

LOUIS DERR.

Thioindoxyl development and its bearing on the theory of the latent image. R. E. CROWTHER. *Phot. J.* 55, 186-99(1915).—Image-reversal in collodion films being thus far unrecorded, and having been definitely established as impossible in a film of pure Ag halide, it appears possible that reversal is at least in part a function of development rather than of exposure. It is conjectured that the action of light is to split the AgBr into Ag and Br progressively, the Ag acting as a nucleus about which development may proceed; or, under suitable conditions, the Ag may be rehalogenized; or, with long exposures, it may become a component of a printed-out image. The Br combines with the gelatin, and the gelatin-Br complex is attacked by the developer while the main development proceeds, the reaction products effecting the reversal. In normal exposures, a certain amt. of the developer is oxidized by the gelatin-Br complex; the oxidation products diffuse into the bath and cease to act, while, with a relatively high conc. of unaltered AgBr, the main development goes on. With exposures giving reversal, there is usually a visible image, rich in Ag and poor in the developable compd. Hence there is little development of the image; and the action of the developer on the gelatin complex forms products similar to those of the normal development of the Ag halide; these cause the observed disappearance of the visible image. With very long exposures, the amount of Br which the gelatin can absorb is exceeded, the excess escaping; hence the entire quantity of Ag in the printed-out image cannot be rehalogenized. This is the second negative stage, in which the deposit is more like a brown stain, quite unlike the normal image. Indoxyl and thioindoxyl as developers yield composite images of Ag and blue indigo or red thioindigo, respectively, and C. shows by their aid that the second negative is residual Ag not rehalogenized by the oxidation products of the developer. From this it follows that a second positive stage of reversal is theoretically unattainable, and, in fact, none such has been observed. L. DERR.

A method of automatic exposure and development. W. GAMBLE. *Phot. J.* 55, 234-41(1915).—A description of the procedure of C. Gravier. An invariable exposure of 0.025 second is adopted for instantaneous work, as for motion pictures. The stop is varied according to the light. The actinometer is a strip of rapid bromide paper impregnated with 5% KNO_3 ; the paper darkens to a limiting heliotrope tint. Development is done with changing-bag and light-proof tray, with adurol or hydroquinone, for a fixed time. Omission of fixing is suggested, if need be, or the developing tray may be used for fixing. In discussion, the necessity of temp. control was emphasized, and a wider range of exposure thought necessary. L. DERR.

Ger., 283,085, Feb. 26, 1914. **FARBW. v. M. L. & B.** Producing photographic pictures in sepia- and red-tones by developing latent pictures by means of hydroxyisocarbostryl and treating the resulting pictures with fixing baths, alone or with fixing and Ag solvents. If, *e. g.*, the picture developed in this manner be fixed with $\text{Na}_2\text{S}_2\text{O}_3$ soln., a beautiful sepia shows up; if, during or after fixing, the picture is treated with a Ag solvent, a red tone is obtained. In general, the so-called "reducers" are used as Ag solvents, such, *e. g.*, as Farmer's reducer, a soln. of $\text{Na}_2\text{S}_2\text{O}_3$ with K_3FeCN_6 added. The hydroxyisocarbostryl developer can be prepared by dissolving hydroxyisocarbostryl in H_2O by means of alkali in the presence of neutral alkali sulfite, if necessary with the addition of KBr . *E. g.*, crystallized Na_2SO_3 10 g., 5 g. anhydrous soda, and 0.5–1 g. KBr are dissolved together in about 100 cc. H_2O . To this is added 1 g. hydroxyisocarbostryl and the soln. is heated to 50° until the latter is dissolved, when it is cooled and filtered. Instead of soda, 2 cc. acetone can be used. The picture appears very quickly in this developer, and is finished after about 3 min.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Notes on sodium columbates. II. Atomic weight of columbium. EDGAR F. SMITH AND W. K. VAN HAAGEN. *J. Am. Chem. Soc.* 37, 1783-97(1915); cf. C. A. 3, 520.—A quantity of K oxyfluocolumbate, dissolved in hot H_2O , was treated with 3 times its wt. of NaOH and the washed ppt. crystd. from boiling H_2O . The crystals were $7Na_2O \cdot 0.6Cb_2O_5 \cdot 31H_2O$ (called "7:6 salt"). This large excess of alkali was necessary to obtain the 7:6 salt, and the yield was conditioned by the amount of alkali used. By spontaneous evapn. of the mother liquor from this process, the salt $Na_2O \cdot Cb_2O_5 \cdot 7H_2O$ was obtained in short, stout triclinic crystals, sometimes 6-7 mm. in length. The 1:1 salt was difficult to recrystallize. The 7:6 salt crystd. in slender needles or prisms, often microscopic in size. It is difficultly sol. in hot H_2O ; becomes lemon-yellow on ignition and white again on cooling. The ignited mass was insol. in H_2O , but part of its alkali splits off, leaving the 1:1 salt, $7Na_2O \cdot 0.6Cb_2O_5 \rightleftharpoons 12NaCbO_3 + Na_2O$. The salts are, then, mutually convertible. The ratio $NaCbO_3:NaCl$ was used for the at. wt. S_2Cl_2 was passed over $NaCbO_3$ until all Cb was expelled, which was accomplished after repeated treatments, alternated with treatments with H_2O . As a mean of 7 detns. of this ratio in a special app. constructed wholly of glass, the at. wt. of Cb was 93.13, if Na = 23.00 and Cl = 35.46. The usual precautions were rigidly observed.

E. B. MILLARD.

Sulfites, thiosulfates, and polythionates. II. A. SANDER. Tech. Hoch., Karlsruhe. *Z. angew. Chem.* 28, I, 273-7; cf. C. A. 9, 2042.—For the prep. of c. p. tetrathionate, 26 g. of I_2 are dissolved in EtOH, cooled, and a satd. soln. of 50 g. $Na_2S_2O_4$ or 39.5 g. $K_2S_2O_4$ run in from a dropping funnel. The tetrathionate formed, being insol. in EtOH, seps. out in small crystals. These are drained and washed with EtOH till free from I_2 and iodides. The crystals are dissolved in the smallest possible quantity of H_2O at room temp. and the crystals again pptd. with EtOH, sucked dry, pressed between filter paper and dried over H_2SO_4 . A number of analyses showed that the tetrathionate thus prepared is very pure. The solid alkali tetrathionates are stable at ordinary temps. The soln. of the pure alkali tetrathionates may be boiled without decomp., but the presence of other salts as impurity at once causes decomp. $Na_2S_2O_4$ with tetrathionates acts to a slight extent only at room temp. At 100° the tetrathionate is rapidly decomposed in the presence of $Na_2S_2O_4$. In this case there is no reaction between the thiosulfate and tetrathionate, the former merely acting as a catalytic agent. L. T. F.

A new tin-sulfur compound, Sn_3S ? G. EPPRECHT. *Chem. Ztg.* 39, 341-2(1915).—During the repair of a furnace used for Sn recovery, the presence of well-formed gray crystals was observed. They are stable in air and appear to be a new compd. The density of the crystals is 5.77. They are not affected by cold dil. acids nor when heated with NaOH soln. The crystals are somewhat impure. The analytical results after correction for impurities indicate a compound of the formula Sn_3S . E. assumes that under the conditions in the furnace the Sn would be in the tetravalent form and suggests that the compound is *distanmic sulfide* of the structural formula $Sn \equiv Sn$.

 W. H. S.

Action of stannous chloride on sulfuric and sulfurous acids. R. G. DURRANT. *J. Chem. Soc.* 107, 622-38(1915).—The action of concd. H_2SO_4 in excess on hydrated $SnCl_2$ results in hydration followed by liberation of HCl between 20 and 90° , and the liberation of SO_2 between 130 and 200° with the formation of $Sn(SO_4)_2$. When heated alone, $SnSO_4$ liberates SO_2 between 360° and a dull red heat, forming SnO_2 . When H_2SO_4 acts on $SnCl_2$ in the presence of water, various reactions caused by dissolved

SO_2 and HCl take place. The H_2S produced is shown to depend upon dissolved SO_2 . The action of H_2SO_3 on solns. of SnCl_2 occurs at room temp. and varies according to the proportions of SnCl_2 , SO_2 , HCl , and H_2O present. The result is a partial or complete oxidation of SnCl_2 . It is slow and incomplete without an excess of HCl . It is evident that 5 reactions are involved. The reaction is bimol., provided that HCl is present in excess. Aside from complete oxidation resulting in the formation of H_2S , the interaction of H_2S and H_2SO_3 occurs to the greatest extent. The interaction of H_2S and SnCl_2 occurs only at high concn. of HCl . SnCl_2 and H_2S react in the earlier stages; SnS appears only when H_2SO_3 is present in slight amt., but it is evident that a colloidal form is produced. The action of SnCl_4 upon H_2SO_3 occurs least of all. To attain complete oxidation the mol. ratios $\text{SnCl}_2:\text{H}_2\text{SO}_3:\text{HCl}$ must be in the proportion 3:1.55:6. Higher proportions of H_2SO_3 and particularly of HCl accelerate the oxidation. W. H. S.

Cuprous carbonate. P. CARLES. *Bull. soc. chim.* 17, 163-4(1915).—During the prepn. of ammoniacal solns. of CuO by the combined action of air and NH_3 upon Cu it was observed that the solvent action gradually became sluggish. The cause was traced to CO_2 , an insol. carbonate slowly forming scales which could be shaken off by boiling water. The outer surface of the scales was blue, the interior a malachite green, and the layer in contact with the metal yellow. In time the blue surface gradually changes to green, and then all becomes reddish yellow. The product when powdered is stable and dissolves in acids with effervescence. With HCl a colorless soln. results; this gives an abundant white ppt. when diluted with water. W. H. S.

"Boric acid water-glass." W. ACKERMANN. *Chem. Ztg.* 39, 225(1915).—A. discusses a fluid compound containing approximately 3 or 4 B_2O_3 to 1 Na_2O prepd. by warming gently a mixt. of borax and boric acid (3:1). The compd. is to be considered analogous to ordinary water-glass; hence it possibly is a colloidal soln. of H_2BO_3 in borax. The fluid compd. is fairly stable though less so than ordinary water-glass, for it tends to solidify and crystallize on standing, especially if shaken. It finds technical application as a flux in soldering, to take the place of borax, over which several important advantages are claimed. Finally it is pointed out that "water-glasses" are met with among the alkali compounds of silicic, phosphoric and boric acids, and that these are more or less closely allied to one another. T. R. BRIGGS.

The action of ammonium salts on mercuric iodide. I. ICILIO GUARESCHI. Univ. Turin. *Atti accad. sci. Torino* 50, 231-6(1915).—In the course of his expts. on metallic bromides G. made some observations with HgI_2 which are reported here. If a mixt. of HgI_2 with a little NH_4Br is heated in a long narrow hard glass tube, violet I vapors are formed. The aq. ext. of the cold mass gives an intense blue coloration with starch soln. The reaction which is shown by as little HgI_2 as 0.0001 g. is due to the formation and subsequent decompn. of NH_4I . The same reaction takes place when the NH_4Br and HgI_2 are heated in aq. soln. This reaction as a qual. test for I is much better than concd. H_2SO_4 . NH_4I heated by itself decomp. thus: $2\text{NH}_4\text{I} \longrightarrow 2\text{NH}_3 + \text{I}_2 + \text{H}_2$ so that the reactions must be $\text{HgI}_2 + 2\text{NH}_4\text{Br} \longrightarrow \text{HgBr}_2 + 2\text{NH}_4\text{I}$ and $2\text{NH}_4\text{I} \longrightarrow 2\text{NH}_3 + \text{I}_2 + \text{H}_2$. The presence of HgCl_2 , HgBr_2 , or PbBr_2 hinders the reaction. The presence of KBr is without effect. Both $(\text{NH}_4)_2\text{SO}_4$ and NH_4NO_3 heated with HgI_2 evolve I vapors but reabsorb them on cooling so that the starch test fails. $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ gives the free I but is not a convenient reagent. Heated with NH_4Cl , HgI_2 gives almost no I. Hg_2I_2 heated with NH_4Br gives no I. The reactions taking place are expressed thus: $\text{HgI}_2 + 2\text{NH}_4\text{Br} \longrightarrow \text{HgBr}_2 + \text{Hg} + 2\text{NH}_4\text{I}$ and $2\text{NH}_4\text{I} \longrightarrow 2\text{NH}_3 + \text{H}_2 + \text{I}_2$ and $\text{Hg} + \text{I}_2 \longrightarrow \text{HgI}_2$. The presence of Hg_2I_2 or Hg_3Br_2 prevents the reaction with HgI_2 . Hg_2I_2 boiled in H_2O with NH_4I gives Hg . The same is true for $\text{Hg}_2\text{I}_2 + \text{NH}_4\text{Br}$. HgI_2 is readily sol. in cold NH_4Br soln. and if the residue

on evapn. is heated I is evolved. This reaction permits of the sepn. and identification of HgI_2 when mixed with large amts. of other insol. red compds.; thus HgS (cinnabar) containing 0.1% of the iodide gives a positive result. This result is not obtained if the mixt. is heated with the NH_4Br soln. since in this case $(\text{NH}_4)_2\text{S}$, S, etc., are formed. No other easy way of finding HgI_2 in HgS is known. HgI_2 dissolves in NH_4Br soln. with a marked diminution in the temp. of the soln. When a mixt. of a little HgI_2 is heated slowly with much MnO_2 , I vapors are evolved at first but later the HgI_2 sublimes. When heated rapidly almost no I is liberated. The addition of NH_4Br to the mixt. causes a marked evolution of I. When $\text{HgI}_2 + \text{Sb}_2\text{S}_3$ are heated with NH_4Br , NH_3 is evolved in large amts., a sublimate is formed, but no I is evolved. When this mixt. is treated with aq. NH_4Br and the dried cryst. residue from the soln. heated, faintly violet vapors form, but no test for I was obtained with starch; the presence of I was shown by the addition of Cl water. II. *Ibid* 354-60.—In continuing his earlier expts., G. heated all metallic iodides, even those like AgI , which withstand high temps. without decomp., in a long, narrow hard glass tube with NH_4Br and found that all yield free I. In most cases the NH_4Br may be replaced with NH_4Cl . In this way many iodides and iodo compounds that would require long processes by any other method may be recognized quickly. In this way as little as 0.0001 KI may be detected even when mixed with a large proportion of a chloride or bromide of an alkali or alkali earth metal. It therefore constitutes a delicate test for I as an impurity in these salts. The double iodides $\text{HgI}_2 \cdot 2\text{KI}$, $\text{HgI}_2 \cdot \text{CdI}_2$ and $\text{ZnI}_2 \cdot \text{KI}$ give I more easily when heated with NH_4Br than when heated without NH_4Br . TlI gives I when heated alone but less easily than when mixed with NH_4Br . AgCl containing AgI treated with an aldehyde and K_2CO_3 gives metallic Ag which dissolved in HNO_3 leaves unchanged AgI (Vanino and Hanser). AgI heated with NH_4Br gives I at once. It likewise gives I with NH_4Br when heated with anything less than a large excess of AgBr . AgCl effectively prevents the detection of I in AgI on heating with NH_4Br , but the following test gives good results, even when only traces of I are present. The mixt. of $\text{AgI} + \text{AgCl}$ is agitated with about 10 times its wt. of NH_4Br in 20 times its wt. of H_2O , the soln. decanted and the liquid tested for I with Cl water and starch or Cl water and CHCl_3 . The double iodide $\text{HgI}_2 \cdot 2\text{AgI}$ readily gives the reaction with NH_4Br . The same result is obtained in the presence of AgBr , or PbBr_2 , but not when AgCl is present. With PbI_2 the reaction is not prevented by the addition of AgI , HgI_2 , PbCl_2 or PbBr_2 . When a mixt. of $\text{HgBr} + \text{NH}_4\text{Br}$ is heated, it fuses, boils and gives a red-brown sublimate and free NH_3 , but not Br. The sublimate is sol. in hot abs. EtOH from which it seps. as a red powder. This reaction is to be studied further.

E. J. WITZEMANN.

The critical temperature at which hydrochloric acid is formed in the evaporation of magnesium chloride solutions. H. HOF. Wansleben. *Chem. Ztg.* 39, 470(1915).—H. finds that HCl first appears at about 157° when pure MgCl solns. are evapd. under conditions which prevent superheating any part of the soln.

J. H. MOORE.

Molybdenum semipentoxide and its salts. F. MAWROW AND M. NIKOLOW. *Sophia. Z. anorg. allgem. Chem.* 92, 135-44(1915).—When the violet compd. $\text{Mo}_2\text{O}_5 \cdot 7\text{H}_2\text{NO}_3 \cdot 3\text{H}_2\text{O}$ is triturated with NH_4OH soln., the product filtered and washed with dil. NH_4OH and then with EtOH , a yellow substance slightly sol. in H_2O , sol. in acids, is obtained; analysis showed this to be ammonium molybdenum semipentoxide trihydrate, $\text{NH}_4\text{Mo}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$. When this compd. is heated in a stream of CO_2 the product is Mo_2O_5 , violet-black powder. Sodium molybdenum semipentoxide trihydrate, $\text{NaMo}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$, was obtained by triturating with NaOH , and on heating in CO_2 it yielded sodium molybdenum semipentoxide, NaMo_2O_5 . Barium molybdenum semipentoxide trihydrate, $\text{BaMo}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$, and barium molybdenum semipentoxide, BaMo_2O_5 , were obtained in a similar manner.

GEORGE W. MORRIS.

Ferric salts of uni- and polyvalent non-substituted organic acids. R. F. WEINLAND AND FR. PASCHEN. Tübingen. *Z. anorg. allgem. Chem.* 92, 81-118(1915).—Previous work has shown that ferric compds. or organic acids contain the Fe either as a complex cation, generally composed of 3 Fe and 6 (or less) acid residues, or as a complex anion. The rule has been that monocarboxylic acids always form the 1st type of compds. while dicarboxylic acids form also the 2nd type; in the present paper derivs. of a number of organic acids are studied to see if the above rule is adhered to. The *mononaphthoate* of a *hexanaphthoato-triferric base*, $[\text{Fe}_3(\text{C}_{10}\text{H}_7\text{CO}_2)_6(\text{OH})_2](\text{C}_{10}\text{H}_7\text{CO}_2)$, from $\text{C}_{10}\text{H}_7\text{CO}_2\text{Na}$ and FeCl_3 , forms orange-yellow powder, sol. in organic solvents; the *nitrate*, from the above compd. and HNO_3 in EtOH soln., forms glittering dark red rhombic plates; the *perchlorate-naphthoate*, $[\text{Fe}_3(\text{C}_{10}\text{H}_7\text{CO}_2)_6(\text{OH})_2]\text{ClO}_4 + [\text{Fe}_3(\text{C}_{10}\text{H}_7\text{CO}_2)_6(\text{OH})](\text{C}_{10}\text{H}_7\text{CO}_2)(\text{ClO}_4)$, from the 1st compd. and HClO_4 , forms dark red glittering crystals; the *compound* $[\text{Fe}(\text{C}_{10}\text{H}_7\text{CO}_2)_2(\text{OH})_2]\text{C}_{10}\text{H}_7\text{CO}_2 + [\text{Fe}_3(\text{C}_{10}\text{H}_7\text{CO}_2)_6(\text{OH})_2]\text{C}_{10}\text{H}_7\text{CO}_2$ by slowly evap. an Me_3CO soln. of the 1st compd., forms brownish red octahedra. On addition of FeCl_3 to a soln. of Na cinnamate a *compound* containing 6 Fe to 13 cinnamic acid residues is obtained; light yellow powder, sol. in organic solvents. On dissolving this compd. in EtOH and adding H_2PtCl_6 soln., reddish brown 4-sided columns of the *chloroplatinate* of the *hexacinnamylato-triferric base*, $[\text{Fe}_3\text{C}_6(\text{OH})_2]\text{O} \cdot 5\text{PtCl}_4 \cdot \text{H}_2\text{O}$ (Ci representing the cinnamyl radical) separate; the *nitrate*, obtained in a similar manner, $[\text{Fe}_3\text{C}_6(\text{OH})](\text{NO}_3)\text{Ci} \cdot 4\text{H}_2\text{O}$, forms brownish red 4-sided tablets; the *perchlorate-cinnamylate*, $3[\text{Fe}_3\text{C}_6(\text{OH})_2]\text{ClO}_4 + [\text{Fe}_3\text{C}_6(\text{OH})_2]\text{Ci} + 15\text{H}_2\text{O}$, long brownish red 4-sided columns. When the above 6:13 compd. is extracted with Me_3CO , indefinite mixts. richer in Fe result. When FeCl_3 is added to a H_2O soln. of Na pyromucate, *ferric pyromucate*, $[\text{Fe}_3\text{Pm}_6(\text{OH})_2]\text{Pm} + [\text{Fe}_3\text{Pm}_6(\text{OH})_2]\text{Pm} + x\text{H}_2\text{O}$ (Pm representing the $\text{C}_4\text{H}_5\text{OCO}_2$ radical), yellowish red ppt., sol. in EtOH, Me_3CO , CHCl_3 , slightly in H_2O , is obtained, which on recrystn. from EtOH yields the *monopyromucate* of the *hexapyromucato-triferric base*, $[\text{FePm}_6(\text{OH})_2]\text{Pm} + \text{H}_2\text{O}$, long yellowish red tablets the *perchlorate*, $[\text{Fe}_3(\text{Pm}_6\text{OH})_2]\text{ClO}_4 + [\text{FePm}_6(\text{OH})]\text{ClO}_4\text{Pm} + 5\text{H}_2\text{O}$, fine yellow needles, is obtained similarly, with addition of HClO_4 ; the *chloride*, $[\text{FePm}_6(\text{OH})_2]\text{Cl}$, yellow needles, is prepd. similarly. *Ferric 2-phenylquinoline-4-carboxylate*, $[\text{Fe}_3\text{Q}_2(\text{OH})_2]\text{Q} + \text{H}_2\text{O}$, is obtained as a white ppt. on addition of FeCl_3 to NaQ ; the *chloride* of the *hexa base* was obtained by recrystn. from EtOH on addition of HCl . Addition of FeCl_3 soln. to Na laurate gives a flesh-colored ppt., whose compn. is probably similar to that of the above compds. When a Na *o*-phthalate soln. was pptd. with FeCl_3 , the reddish brown ppt. obtained contained Fe:Phth (Phth representing $\text{C}_6\text{H}_4(\text{CO}_2)_2$) in the ratio 3:3.12; when this ppt. was boiled with EtOH and phthalic acid under a reflux condenser, the *mono-o-phthalate* of a *diphthalato-triferric base*, $[\text{Fe}_3\text{Phth}_2(\text{OH})_2]\text{Phth} + 3\text{H}_2\text{O}$, yellow powder, was obtained. When the heating under a reflux was carried out in the presence of HNO_3 , the *nitrate-phthalate* of a *triphtalato-triferric base*, $[\text{Fe}_3\text{Phth}_2(\text{OH})_2]\text{Phth}(\text{NO}_3)_2 + 8\text{H}_2\text{O}$, orange-yellow powder, was obtained, while heating with HClO_4 gave the *perchlorate-phthalate*, $[\text{Fe}_3\text{Phth}_2(\text{OH})_2]\text{Phth}(\text{ClO}_4)_2 + 18\text{H}_2\text{O}$. The *isophthalate* of a *tri-isophthalato-triferric base*, $[\text{Fe}_3\text{Phth}_3(\text{OH})]\text{Phth} + x\text{H}_2\text{O}$, was obtained from Na isophthalate and FeCl_3 , insol. in EtOH or other organic solvents. FeCl_3 and Na terephthalate yielded a dark brown ppt., which could not be freed from the admixed acid. Addition of FeCl_3 to Na camphorate soln. gave the *monocamphorate* of a *tricamphorato-triferric base*, brownish red powder, decompd. by heating with EtOH and organic acid. An *acid camphorate-perchlorate* of the above base, yellowish red powder, was obtained by adding H_2O to a soln. of camphoric acid and $\text{Fe}(\text{ClO}_4)_3$ in 50% EtOH; the *acid camphorate-nitrate*, yellowish red powder, was obtained in a similar manner. Na succinate and FeCl_3 gave a gelatinous ppt.; the *nitrate-succinate* of a *trisuccinato-triferric base*, $[\text{Fe}_3\text{C}_4\text{H}_4(\text{CO}_2)_2(\text{OH})_2](\text{C}_2\text{H}_4\text{CO}_2)\text{NO}_3 + 10\text{H}_2\text{O}$, brown

powder was obtained from succinic acid and $\text{Fe}(\text{NO}_3)_3$ in EtOH soln. The fumarate of a difumarato-trisferric base, $[\text{Fe}_3\text{Fu}_2(\text{OH})_3]\text{Fu} + x\text{H}_2\text{O}$, flesh-colored powder, was obtained from FeCl_3 and Na fumarate. A chloride-fumarate of a trifumarato-trisferric base was obtained by heating a H_2O soln. of FeCl_3 and fumaric acid, and extracting the excess acid from the filtered ppt. with EtOH; a perchlorate-fumarate and a nitrate-fumarate were obtained in a similar manner. Expts. were also made with maleic acid and with oxalic acid in an attempt to obtain ferric derivs., but without success. An Fe salt of hemimellitic acid, $[\text{Fe}_3(\text{C}_6\text{H}_2)(\text{CO}_2)_3(\text{OH})_3](\text{C}_6\text{H}_2)(\text{CO}_2)_3 + x\text{H}_2\text{O}$, was obtained as a chocolate brown powder by dissolving hemimellitic acid in NaOH soln. and adding FeCl_3 ; the Fe salt of aconitic acid was obtained in a similar manner. G. W. M.

Approximate determination of the boiling points of the alkali halides. L. H. BORGSTROM. Helsingfors. *Med. Finska Kemistsamfundet* 24, 2 pp.(1915) (Swedish).—The salts were heated in Pt crucibles by a blast lamp or elec. furnace, and the temps. observed with a Pt-Rh thermoelement. As a mean of several detns., varying $10-20^\circ$, the following values were obtained: LiCl 1360° , NaCl 1490° , NaBr 1455° , NaI 1350° , KCl 1500° , KBr 1435° and KI 1420° . E. T. WHERRY.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Application of petrographic methods to analytical chemistry. W. H. FRY. Washington. *Science* 42, 89-90(1915).—Attention is called to the great value of petrographic microscopic methods in analytical chemistry, and it is urged that the methods be more generally used by chemists. GEORGE W. MORREY.

Specifications for sampling liquids. Report of sub-committee of American Society for Testing Materials. *Drugs, Oils and Paints* 31, 47(1915).—*Liquids contained in containers capable of agitation.* With barrels, after agitation, a tube is to be inserted so as to be filled completely. *Samples from tank cars.* No recommendations at present in view of the difficulty in obtaining a representative sample. Three methods are outlined, e. g., the thief method, sampling from a pipe line and sampling at point of efflux by taking samples at regular intervals or by diversion of a portion of the stream.

E. W. BOUGHTON.

Methods of determination and separation of iron, aluminium, chromium, zinc and manganese. G. VAN PELT. *Bull. soc. chim. belg.* 28, 101-27, 138-43(1914).—V. P. discusses the theory of the hydrolysis of salts in aq. soln. and the method of sepn. of Fe, Al, Cr, Zn and Mn which depends on the different degrees of hydrolysis of salts of bivalent and trivalent elements and the change in equil. due to fixation of HCl by BaCO_3 , KI and KIO_3 and the action of Na succinate or AcONa and AcOH . The general subject of sepn. and detn. of Al, Fe, Cr, Mn and Zn is then treated under the following heads: (1) hydrolysis of aq. solns. of salts of Al, Fe, Cr, Zn and Mn; (2) exptl. verification of the methods based on the hydrolysis of aq. solns.; (3) exptl. verification of the methods based on the oxidation of certain of these elements. The degree of hydrolysis of aq. solns. of AlCl_3 , FeCl_3 , CrCl_3 , MnCl_2 and ZnCl_2 was measured by means of the catalytic action (due to H^+) of these solns. on the velocity of sapon. of diazoacetic ester, the rate of evolution of N being taken as an index of this velocity and the general procedure being according to the method described by Fraenkel. The influence of Cl^- was eliminated by using only the data obtained at the beginning of the reaction. These measurements showed that the salts of Fe and Al are hydrolyzed in the proportion of approx. 80%, while those of Cr and Mn are hydrolyzed in the proportions of approx. 40 and 10%, resp.; the salts of Zn are not hydrolyzed. The principle of the hydrolysis method is, therefore, inexact, inasmuch as the salts of Mn are distinctly

hydrolyzed and the moderate degree of hydrolysis of Cr salts causes the pptn. of Cr to be much slower than that of Fe and Al. The Jannasch method for the sepn. of Cr and Mn does not give satisfactory results, while the method of Dittrich and Hassel is not reliable in the case of chlorides. V. P. proposed the following procedure: add 2 g. crystd. $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and several drops conc. HNO_3 to the soln. of CrCl_3 and MnCl_2 in 300-400 cc. and heat on H_2O bath until a yellow coloration appears. Add the cooled soln. to 75 cc. NH_4OH and 75 cc. H_2O_2 with stirring, warm for $\frac{1}{2}$ hr., decant, wash with H_2O containing NH_4OH and filter; acidify the wash H_2O (which contains Cr as the chromate) with HCl , conc. to 1 cc. and add H_2O_2 . Then ppt. the CrCl_3 with NH_4OH after heating. For the sepn. of Zn and Mn pour the soln. of Mn and Zn salts (in 50 cc. vol.) with shaking into a mixt. of 50 cc. NH_4OH , 25 cc. of a 10% NH_4Cl soln. and 100 cc. H_2O_2 ; add gradually 50 cc. conc. H_2O_2 to this mixt. and warm for approx. $\frac{1}{2}$ hr. on the H_2O bath. After standing 1 hr. wash the Mn ppt. with warm H_2O containing NH_4OH , decant and filter; ppt. Zn from the filtrate with Na_2CO_3 . For the sepn. of Mn, Cr and Zn add 1 cc. conc. HNO_3 to the soln. of the salts (in 200-300 cc. vol.), then add 2 g. $(\text{NH}_4)_2\text{S}_2\text{O}_8$, heat until yellow coloration ensues and allow to cool; pour the soln. into a mixt. of 50 cc. 10% NH_4Cl soln., 75 cc. NH_4OH and 75 cc. H_2O_2 and warm on H_2O bath until Mn is completely pptd. Decant and filter as above, add several drops H_2O_2 to the filtrate, evap. to dryness, redissolve in H_2O , add 20 cc. NH_4Cl soln., ppt. Cr with NH_4OH at b. temp. and ppt. Zn in the hot filtrate with Na_2CO_3 . For the sepn. of Fe and Cr (the Jannasch method is not reliable) acidify with HNO_3 (as in sepn. of Cr and Mn), add $(\text{NH}_4)_2\text{S}_2\text{O}_8$ (to transform Cr to the chromate form) and ppt. Fe with NH_4OH ; the sepn. of Cr and Al may be effected in the same manner. For the sepn. of Fe, Al, Cr, Mn and Zn acidify the soln. of the salts (in 200-300 cc. vol.) with HNO_3 , add 2 g. crystd. $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and warm until Cr is completely oxidized; pour the cold soln. into a mixt. of 25 cc. 10% NH_4Cl soln., 75 cc. conc. H_2O_2 and an excess of NH_4OH , warm until $\text{Fe}(\text{OH})_3$, $\text{Al}(\text{OH})_3$ and $\text{Mn}(\text{OH})_2$ are completely pptd., wash the ppt. with dil. NH_4OH , decant and filter. Heat the hydroxides in a Pt crucible with 3 g. Na_2CO_3 and 3 g. KNO_3 until quiet fusion is effected, repeat the operation with 2 g. each of Na_2CO_3 and KNO_3 , dissolve the melt in H_2O and filter the aluminate and manganate from the insol. Fe oxide; dissolve the traces of the latter attached to the Pt with HCl and ppt. with NH_4OH . Transform the manganate into the manganous salt by acidification and addition of a small amt. of H_2O_2 , render the soln. strongly alk. with NaOH , ppt. Mn with H_2O_2 and ppt. Al with NH_4OH in the acidified filtrate. The filtrate from the 1st pptn. contains Cr and Zn; evap. the acid soln., add H_2O_2 and dissolve in H_2O with addition of NH_4Cl . Ppt. Cr with NH_4OH and then ppt. Zn in the filtrate with Na_2CO_3 .

H. S. PAINE.

Analysis of ferro-chrome. H. SCHILLING. Baildonhütte. *Chem. Ztg.* 39, 466 (1915).—An improvement of Knorre's method. To 0.5 g. ferro-chrome in a small covered beaker add 10 cc. H_2SO_4 (1.84), then cold, distd. H_2O , drop by drop, till the max. reaction occurs (about 10 cc. H_2O is required). When the violent reaction is over add 2 drops HF and warm gently till soln. is complete; then follow Knorre's method. If a detn. of Si is desired, evap. the H_2SO_4 soln., without adding HF , till SO_3 just begins to come off, cool, dil. with H_2O , filter and weigh the SiO_2 (which contains some Cr), treat with HF and weigh again. All other constituents are detd. in the usual way, after oxidation.

J. H. MOORE.

Determination of ferrous iron in silicates by titration with dichromate. O. I. BARNBEY. *J. Am. Chem. Soc.* 37, 1829-35 (1915).—Fe cannot be titrated with $\text{K}_2\text{Cr}_2\text{O}_7$ in the presence of HF ; the addition of H_3BO_3 removes HF by forming HBF_4 . The indicator color appears slowly in the presence of fluorides, and the slowness increases with increasing quantities of $\text{K}_2\text{Cr}_2\text{O}_7$. Expts. showed that the sensitiveness of the ferri-

cyanide test decreases with increasing concn. of acid, whether HCl or HF, but that HF is much worse than HCl in concealing Fe. The sensitiveness of the test is reduced from 1 in a million in the absence of HF to 1 in 14000 in the presence of 2.5 N HF. Small amts. of Fe can be titrated accurately in the presence of even 2.5 N HF if H_3BO_3 be added. Addition of $FeCl_3$ to the $K_3Fe(CN)_6$ on the spot plate increases the sensitiveness of the test in the presence of large amts. of HCl. (In an added note B. suggests the use of acetone as a drying agent in glassware, in place of alc. and Et_2O , since the acetone is easily removed by a current of air.)

E. B. MILLARD.

The separation of potassium and sodium by the use of aniline perchlorate, and the subsequent estimation of the sodium. D. U. HILL. Yale. *Am. J. Sci.* 40, 75-7 (1915).—Pptn. of NaCl from EtOH soln. by HCl, after removal of K as $KClO_4$, gives results about 1% low. Substitution of aniline perchlorate for $HClO_4$ as a pptnt. of K was also tried but results were low. Prepn. of aniline perchlorate by evapn. of NH_4ClO_4 with aniline was not satisfactory, the decompn. being slow and the product dark colored. The best method of prepn. is to prepare $HClO_4$ by Willard's method, add aniline in slight excess to a H_2O soln. of the acid, then boil until the excess aniline is removed.

GEORGE W. MOREY.

New method for the iodometric estimation of thiocyanic acid and of hydrogen sulfide. F. P. TREADWELL AND C. MAYR. Zürich. *Z. anorg. allgem. Chem.* 92, 127-34 (1915).—The method is based on the use of Br, liberated by the action of acid on $KBrO_3$ and HBr, as an oxidizing agent, and the titration of the excess Br in the usual manner. For the detn. of HCNS, either alone or in the presence of HCl or HBr, but with HI absent, place 5 or 10 cc. of a 0.2 N soln. in a stoppered 1 l. flask, add 50 cc. 0.2 N $KBrO_3$ soln. and 10-15 cc. 10% KBr soln., evacuate the flask under a water pump, and add concd. HCl through a dropping funnel until the vol. of liquid is increased one-third. Then let the flask stand 10-15 min., add concd. KI soln. through the dropping funnel, and titrate the soln. with $Na_2S_2O_3$, using starch. In case both HCNS and HCl (or HBr) are to be detd., det. the HCNS as above, and $HCNS + HCl$ (or HBr) by the Volhard method; then the latter can be calcd. In the titration of H_2S by the above method the S is completely oxidized to H_2SO_4 , instead of to S as is the case when titrating with I, making the former method 4 times as sensitive as the latter; the actual operation is carried out as described above. When both HCNS and H_2S are to be detd., det. the total S in one portion by the $KBrO_3$ -KBr method, the H_2S by titration with I in the usual manner; then the HCNS can be calc. Results given are good.

GEORGE W. MOREY.

An improved method for the detection of cobalt by means of α -nitroso- β -naphthol. F. W. ATTACK. *J. Soc. Chem. Ind.* 34, 641-3 (1915).—The test for Co by means of α -nitroso- β -naphthol is greatly increased in delicacy by the use of the Na salt, instead of the oxime in EtOH soln. The reagent is prepd. by boiling 0.1 g. α -nitroso- β -naphthol with 20 cc. H_2O to which has been added 1 cc. dil. NaOH, filtering, and diluting to 200 cc.; the soln. so prepd. is stable over a year. To test for Co add 1 cc. NH_4Cl [strength not given.—ABSTR.] and then 1 cc. of the reagent to the soln. to be tested; an orange to red coloration or a red ppt., unaffected by the addition of dil. H_2SO_4 , indicates Co. 0.001 mg. Co in 1 cc. soln. can be detected by this reagent. The coloration due to Ni, Fe^{+++} , etc., is destroyed by the H_2SO_4 , and Mn, Zn, tartaric acid or citric acids do not interfere. Large amts. of Ni must be removed.

GEORGE W. MOREY.

Determination of chlorine in vegetable matter. D. J. DE JONG. Gröningen. *Chem. Weekblad* 12, 592-4 (1915).—Wet the sample (10-15 g.) with 10 cc. of 10% Na_2CO_3 soln., then ignite, and det. the Cl in the melt.

GEORGE W. MOREY.

Brit., 6,767, Mar. 17, 1914. SIEMENS & HALSKE AKT.-GES. Addition to 28,943, 1912 (C. A. 8, 1890). **Gas analysis.** In the process of the principal patent, the relative proportions of gases present in a gaseous mixt. of known constituents are detd. by a comparison in a single instrument of the pressure differences produced by centrifugal blowers, etc., working under the same conditions in the gaseous mixt. and in the standard gas. In the present modification, the pressure difference produced in the standard gas is automatically maintained at a constant value independent of changes of temp. and pressure, the proportion of gases in the gas mixt. being still shown by the reading of a single instrument.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

The melting and boiling points of metalloid-sulfide, selenide, and telluride minerals. L. H. BORGSTRÖM. Helsingfors. *Öfvers. Finska Vetensk. Soc. Förh. (A)* 57, No. 24, 13 pp. (1914-5).—The usual methods of detg. mineral m. ps. have certain disadvantages, and to overcome these B. has introduced a procedure corresponding to that used in organic chem., namely, the placing of a minute amt. of the mineral in a capillary tube and heating in a liquid the temp. of which can be observed. The liquids used for this purpose were, for temps. of 220–450°, 55 pts. $\text{NaNO}_3 + 45 \text{ KNO}_3$; 380–650°, 3 $\text{KCl} + 1 \text{ LiCl}$; 630–850°, 7 $\text{Na}_2\text{SO}_4 + 3 \text{ NaCl}$; and above 810°, pure NaCl . The temps. were measured with a Pt-PtRh thermoelement, which, it was found, could be safely introduced into the bath without any protecting casing, thereby increasing the accuracy of the method. By watching the samples closely as the heat increases, the m. p. can in most cases be readily detd. Since the amt. of air in the capillary is very small, even easily oxidizable minerals can be thus examd. The behavior of the 7 minerals studied is described in detail, and the most satisfactory values for the m. ps. given as: realgar 310, orpiment 320, kermesite 517, stibnite 546, tetradymite 600, guanajuatite 690, and bismuthinite 718°; the b. ps. for the first 3 as 589, 690 and 990°, respectively. The limits of accuracy of these detns. would appear to be about $\pm 5^\circ$. The occurrence of these minerals is then discussed, and by tabulating their m. ps. and modes of occurrence it is shown that in a general way those with the lowest m. ps. form under conditions of low temp. and pressure, near the surface of the earth, while the higher the m. p. becomes the more the mineral is found in deep-seated rocks.

E. T. W.

Study of the relations existing between the chemical, optical and other physical properties of the members of the garnet group. W. E. FORD. New Haven. *Am. J. Sci.* 40, 33-49 (1915).—From the literature selected analyses of 23 garnet minerals, in which the n and in most cases the sp. gr. had been observed, were tabulated. Mol. ratios were obtained from each analysis; the discrepancies between these numbers and theory were averaged and from these new values the analyses were recalcd. and reduced to a 100% summation. From these modified analyses the % of the mols. corresponding to the different garnets were derived. In addition all the available garnet analyses were collected and, after the elimination of those of unusual comp., about 200 were studied with reference to their content of the 5 common members of the group (pyrope, grossularite, spessartite, almandite, and andradite). It was found that about 15% contained 4 or more isomorphous mols.; the remaining 85% contained 2, or more frequently 3, which made up more than 95% of the total comp. This study showed that in any given series formed by the mixt. of 3 garnet mols., 2 predominate, the third mol. being present in very subordinate amts. Analyses of 64 garnets were studied to learn the relations between comp. and sp. gr. using the following sp. gr. values for the component mols.: pyrope 3.51, grossularite 3.53, andradite 3.75, spessartite 4.18,

almandite 4.25. The results of this study are shown by 9 figures of equilateral triangle plotting. It appears to be established that the n and the sp. gr. of any garnet depend in a direct and simple way upon its chem. comp. "Having given these physical constants, and knowing from qual. tests the predominant mols. present, it should be possible in the majority of cases to predict within reasonable limits the comp. of the mineral." The relationships between sp. gr., n and mol. wt. seem fairly constant until the andradite mol. becomes prominent; this causes a distinct break in the continuity of these relations. It is noted that andradite has the highest mol. wt. of all the garnets. While the relationship between sp. gr. and index of refraction (n) is often a reasonably definite one, there are apparent exceptions which at present do not admit of explanation. L. W. R.

Remarkable contact-metamorphic phenomena of the granite of Madagascar (imerinite). A. LACROIX. *Compt. rend.* 160, 724-9(1915).—The observations refer to a locality east of the middle of the island, in the province of Imerina. The ribbon-like limestone, resembling marble, instead of including diopside, tremolite or actinolite (which are common in that region) as the principal metamorphic mineral, contains an abundance of a new type of amphibole, which L. names *imerinite*, and which has the comp.: SiO_2 53.73, TiO_2 0.41, Al_2O_3 2.72, Fe_2O_3 4.72, FeO 4.70, MgO 20.60, CaO 2.73, Na_2O 7.42, K_2O 1.82, H_2O 0.85, F 0.92, sum 100.62%. While its chem. comp. allies it to the richterites and glaucophanes, in its optical characters it resembles the rhodusites, being distinguished from the latter chemically by its low sesquioxide content. *Imerinite* forms clear, dark blue crystals 2 cm. in length, or fibrous lavender-blue masses; it constitutes the local amphibolites, including always a little calcite. On the borders of the limestone the imerinite is associated with fine lamellas of microcline, albite, quartz grains and with amphibolic needles throughout the mass. There is also present monazite, which would not be expected under these conditions, accompanied by celestite. Analysis of the monazite (by Pisani) gave: P_2O_5 30.18, ThO_2 1.05, Ce_2O_3 39.51, $(\text{LaDi})_2\text{O}_3$ 27.80, Fe_2O_3 0.92, CaO 0.46, loss on ignition 0.47, total 100.39%; sp. gr. = 5.25. This monazite is unusual in the low Th content. The metamorphism at contact with granite is discussed at length, mainly from a petrographic point of view. L. W. RIGGS.

Identity of calciocancrinite and meionite. L. H. BORGSTRÖM. Helsingfors. *Öfvers. Finska Vetensk. Soc. Förh.* (A) 57, No. 6, 3 pp.(1914-5).—The mineral discovered by Lemberg in 1876 and named calciocancrinite (Kalkcancrinitt) has been regarded as "a combination of anorthite with CaCO_3 " and as a typical member of the cancrinite group. Recent studies by B. (C. A. 9, 189) having shown that meionite is also a combination of anorthite and CaCO_3 , the nature of Lemberg's material has been reconsidered. The 2 are found to agree closely in properties and comp., analyses of both conforming essentially to the same formula, $\text{CaCO}_3 \cdot \text{CaAl}_2\text{Si}_2\text{O}_8$; they are, therefore, evidently identical.

E. T. W.

Two minerals from Baveno containing rare earths: weibyeite and bazzite. E. E. ARTINI. *Atti accad. Lincei* 24, I, 313-9(1915).—A. has identified weibyeite, a Ce carbonate, by its cryst. form, in the granite of Baveno. In addition a very rare, hitherto unknown, mineral was obtained from the same source. This mineral appears as very small blue hexagonal prisms, which are uniaxial with strong double refraction. The main ns . were detd. in a mixt. of monobromonaphthaline and vaseline; for the Na line, the internal nucleus had $\epsilon = 1.608$, $\omega = 1.626$, the external zone $\epsilon = 1.602$, $\omega = 1.623$. The mineral is strongly pleochroic; intense sky blue to pale green. It is unattacked by acids (except HF). Fused with Na_2CO_3 and taken up with HCl the main constituent was found to be SiO_2 ; NH_4OH ppts. $\text{Fe}(\text{OH})_3$ and a white ppt. of the hydroxides of the rare earths, which because of the small amt. available was examd. microchemically. With oxalic acid, crystals identified as Sc oxalate were obtained. The mineral is,

therefore, a Sc silicate, containing some other rare earths, possibly Ce, some Fe and a little Na. The mineral is called *bazzite*, after its discoverer. E. J. WITZEMANN.

Cataclase in meteoric iron. S. MEUNIER. *Compt. rend.* 160, 736-9(1915).

L. W. RIGGS.

The composition and structure of the Indarch, Russia, meteoric stone. GEORGE P. MERRILL. U. S. Nat. Mus. *Proc. U. S. Nat. Mus.* 49, 109-12(1915).—This stone, unusual in containing oldhamite and a CO₂-bearing mineral, perhaps breunnerite, has the total comp.: SiO₂ 35.699, Al₂O₃ 1.969, FeO 25.790, MnO 0.130, NiO 0.549, CoO 0.049, CaO 1.160, MgO 16.920, CO₂ 0.271, P₂O₅ 0.520, H₂O 2.799, Fe 10.400, Ni 0.949, Co 0.020, P 0.092, Mn 0.119, C 0.310, S 5.100, less O = S 2.540, sum 100.306. No Ba, Sr, or Zr could be detected; the sp. gr. = 3.42 and the mineral comp., detd. by combining results of microscopic exam. and the analysis is: enstatite 74.42, metal 11.50, troilite 13.296, oldhamite 0.596, graphite 0.310, sum 100.122%. Attention is called to the occurrence of oldhamite in stones of a wide range of comp. (cf. C. A. 9, 2208).

E. T. W.

The spark spectrum of N'Kandhla meteorite and of other meteoric irons. JOSEPH LUNT. *S. African J. Sci.* 11, 243-52(1915).—A spectrographic exam. supplementing the chem. exam. by Stanley (*Rept. S. African Assoc. Adv. Sci.* 10, 105; also C. A. 7, 2534) is described.

J. H. BOWER.

The formation and distribution of bog iron-ore deposits. C. L. DAKE. Rolla, Mo. *Bull. Am. Inst. Mining Eng.* 1915, 1429-36; cf. C. A. 9, 13.—These ores originate from natural ferrous salts or ferric salts reduced by organic matter, which are dissolved and carried to bogs where they ppt., either by oxidation, by loss of CO₂, or by bacterial action. They consist essentially of limonite with subordinate amts. of carbonate, are usually high in P and preserve abundant fossil plant fragments. They are widely distributed but occur chiefly in the colder temperate regions within the glaciated area, probably because there the swamps are more numerous and are of small size and so allow greater conc. of "chalybeate" waters. Furthermore, glacial soils contain much available Fe.

H. L. OLIN.

Additional data on origin of lateritic iron ores of eastern Cuba. C. K. LERTH AND W. J. MEAD. *Bull. Am. Inst. Mining Eng.* 1915, 1377-80; cf. C. A. 5, 1891.—Results of analyses of 29 samples grading from the unaltered serpentine rock to the lateritic ores above are given. Starting with the bed rock, MgO and SiO₂ are lost rapidly; Al₂O₃, Fe and Cr increase in % with the loss of SiO₂ and MgO. Fe reaches const. max. % at the same depth that SiO₂ reaches its min. %. The marked loss of Ni and Co during the formation of the ore suggests the possibility of secondary downward conc. of these metals.

H. L. OLIN.

The Mayari iron-ore deposits, Cuba. JAMES F. KEMP. *Bull. Am. Inst. Mining Eng.* 1915, 1461-2; cf. C. A. 9, 903.—In this postscript K. corrects his previous statement that the ores contain no fossils, having found on closer exam. a small foraminifer (*Orbitoides*) probably an Oligocene form.

H. L. OLIN.

Origin of thick gypsum and salt deposits. E. B. BRANSON. *Bull. Geol. Soc. Am.* 26, 231-42(1915).—The theory proposed is a modification of the "bar" theory, consisting in supplying the basins with highly conc. waters instead of normal sea water. In the drying up of a large interior sea the waters might come to lie in separate basins if the bottom were uneven. Assuming that isolated basins were formed, separated by low barriers, and that the main streams emptied into the marginal basins, the inflow might be sufficient to cause these basins to overflow and supply the inner basins, that had no direct stream connection, with highly charged waters as fast as their own waters evaporated. With the high conc., life would have ceased to exist in the supplying basins

before gypsum deposited and no fossils would be present. The filling up of the outer basins with sediments would cause more water to flow over to the inner basins, and this fresher water might entirely stop the gypsum deposition by causing the inner basins to overflow, and would also prevent any salt from being deposited. W. F. HUNT.

Oil, gas, and water content of Dakota sand in Canada and United States. L. G. HUNTLEY. *Bull. Am. Inst. Mining Eng.* 1915, 1333-53.—H. discusses the age and nature of deposition of Dakota sand, its lithologic character, the extent of its outcrop in Canada, the tar sands and production of oil (including analysis), the presence of gas, salt water and fresh water, the structure, pressures and geological history. The following summary is given: (1) In general, on account of the very uniform character and thickness of the Dakota sand over wide areas, it is not believed to be a prospect horizon of the first class for the development of oil production except in certain limited districts. (2) In Canada it is believed that the most favorable areas for the development of oil production in this sand will be found in the region where it begins to play out and become discontinuous and lenticular in its nature. This is the case in the oil pools of Wyoming producing from it and points to certain parts of Montana as worthy of prospecting. (3) While not a prospect of the first order, the testing of the Battle River anticline for oil in the Dakota is distinctly worth while. This anticline is for the foregoing reasons, more favorable for gas in this sand; and oil should be looked for, if at all, in the more laterally restricted sands occurring in the Benton or Niobrara, or higher. (4) The chances for the development of oil production in the formations lying below the Dakota in western Canada are not of the first class from the com. standpoint. (5) Where structural and other conditions are favorable for the conc. of oil, the relatively lenticular sand bodies above the Dakota, particularly the Benton and Niobrara, are more promising for the development of production than is the Dakota sand itself (except in the regions noted). J. H. BOWER.

The possible occurrence of oil and gas fields in Washington. CHARLES E. WEAVER. *Bull. Am. Inst. Mining Eng.* 1915, 1419-21.—From the geological conditions known to exist in the Cascade Mts. and in eastern Wash. the chances for the occurrences of petroleum are unfavorable. The Eocene formations in the Puget Sound Basin were laid down under conditions which would not allow the accumulation of organic matter, while the overlying Miocene strata, which were involved in a great anticlinal fold, have been so eroded that any oil deposits that may have existed must have been destroyed. The Jurassic of the western side of the Olympic peninsula presents possibilities. H. L. OLIN.

Obsidian from Hrafninnuhryggur, Iceland; its lithophysae and surface markings. FRED. E. WRIGHT. *Bull. Geol. Soc. Am.* 26, 255-86(1915).—The obsidian varies from a dense black glass to a rock approaching pumice. The glass has $n =$ about 1.500 and $d = 2.387$. It contains numerous minute crystallites of a colorless prismatic mineral. The analysis corresponds to that of a normal rhyolitic obsidian and includes 0.27% H_2O , 0.13% Cl, and 0.07% SO_3 . The release of these volatile components in the magma was largely responsible for the formation of the lithophysae, while the character of the physico-chem. system thus produced caused the simultaneous formation of crystals of fayalite and tridymite at relatively low temps. Hot circulating solns. acting on the more porous and exposed portions of the obsidian have produced some alunite, hyalite, and etched surfaces which resemble moldavitic markings. W. F. HUNT.

A new gypsum-bearing deposit in Senigallia. C. AGOSTINELLI. *Univ. Pavia. Rass. min.* 42, 101-3(1915).—On the extreme western declivity of Monte d'Oro is found a blue-grayish marl in regular strata 10-40 cm. thick, and further up an extremely friable, clayey-sandy, yellowish material in barely perceptible and almost horizontal strata. The blue marl is quite compact, mixed here and there with very fine, sky-blue

clay, occasional particles of quartz sand and very numerous crystals of gypsum, together with a few nodules of S. Comp. of the blue marl: H_2O 22.25, CO_2 1.22, SiO_2 1.61, SO_2 42.54, free S 0.11, Fe_2O_3 0.81, Al_2O_3 0.22, CaO 30.81, MgO 0.48%; of the yellowish marl: H_2O 7.30, CO_2 11.14, SiO_2 37.44, SO_2 1.34, P_2O_5 0.87, Fe_2O_3 20.92, Al_2O_3 0.98, CaO 9.32, MgO 3.14, free S 0.06, K_2O 4.38, Na_2O 3.14%. C. A. ROULLIER.

Report on some carbonic acid tests on the weathering of marbles and limestones. GEORGE P. MERRILL. U. S. Nat. Mus. *Proc. U. S. Nat. Mus.* 49, 347-9(1915).—Cubes of various samples about an inch in diam. were rubbed smooth with emery flour, weighed, and suspended in H_2O through which a slow current of CO_2 passed. After 3 months they were weighed and examd. for changes. The smallest amt. lost was 0.0009%, by marble from Cockeysville, Md.; the largest 0.050%, by oolitic limestone from Salem, Indiana. From a practical point of view, however, the amount of material lost is not as important as the manner in which loss occurs. In some stones the whole surface is dissolved uniformly; others become roughened, granules being loosened; in others, small interstitial crystals dissolve out, leaving the larger grains in relief; while in oolitic rocks the oolites are eaten out, although their shape may be retained by insol. impurities. Tables of the results with 19 different rocks are given. E. T. W.

Clay and shale deposits of Quebec (KEELE) 19.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Progress in metallurgy. JAMES DOUGLAS. *Bull. Am. Inst. Mining Eng.* 1915, 763-6.—A brief address. E. J. C.

The consulting metallurgist and metallurgical investigations. W. B. BLYTH. *Proc. Australasian Inst. Mining Eng.* 16, 403-38(1914).—B. discusses the difficulty of making correct comparison between the results obtained from the exam. of small parcels of Au ore and the results expected from the continuous working of large plants on the same ore. A description of the many varying factors which influence treatment in Au metallurgy in western Australia is given, including hardness of ores, roasting, amalgamation, leaching, slime settlement and vacuum filter capacity. Charts and curves are given. WEBBERT.

Precipitating action of carbon in cyanide solutions. O. C. RALSTON. *Mining Sci. Press* 111, 77-8(1915).—Discussion of article by W. R. Feldtmann (cf. C. A. 9, 1891). R. explains certain facts already known about charcoal, which in conjunction with colloid-chem. principles further support Feldtmann's work in explaining the pptn. of Au on charcoal. L. A. TOUZALIN.

Metallurgy (of vanadium) at the Primos Chemical Co.'s plant. ANON. *Mining Eng. World* 43, 105-6(1915).—A description of the practice at Vanadium, Colo. The ore, a soln. of roscoelite in sandstone, contains 1 to 3% of V. A charge of 1500 lbs. of ore, 90 lbs. of NaCl and 30 lbs. of FeS, ground to pass a 30-mesh screen, is roasted in a McDougal and a Wedge roaster, both fired by oil. The ore from these roasters is cooled and discharged into a launder containing a weak soln. of Na_2VO_4 , and is then carried to the leaching vats. These vats are of steel with a flat bottom and have a canvas or cacao matting filter. There are 5 vats, each 100 tons capacity; they are filled in 18-22 hrs. and the usual practice is to have one filling, one empty in reserve, one being discharged, and 2 leaching. The strong soln. containing 6 to 12 g. of V per l. draining off from the tank being filled, passes to a sump tank, from which it is pumped into steel storage tanks for cooling and further treatment. The weak soln. from the 2 tanks being leached passes to another sump tank. Both of these sump tanks overflow when nearly

full into a third sump; the soln. in the latter is pumped into the launder carrying the ore from the conveyor to the leaching vats. This soln. is kept weak by adding H_2O when necessary and varies from 1.5 to 4 g. per l. By keeping this soln. at about 4 g. under normal conditions the strong soln. delivered to the storage tanks will average 7 to 8 g. This is best strength for pptg. the V. The vats are leached with hot H_2O from the roasters at the rate of 3.5 ft. per hr. About 36 hrs. are required to leach a vat and when the soln. draining from a vat shows less than 0.1 g. of V per l. the vat is discharged. The 5 mill storage tanks are filled in rotation: one filling, 3 cooling, and one being transferred. Cooling renders pptn. of V more complete and is effected by an air jet extending down into the tank at the center and discharging at the bottom. Av. capacity of tanks = 60 tons. The cool soln. is transferred to 3 pptn. tanks (50 tons capacity each) in rotation: one filling, one in process of pptn., and one discharging. The soln. is agitated by air to prevent the ppt. from settling. Pptn. is effected with $FeSO_4$, theory requiring 2 lbs. of $FeSO_4$ to ppt. 1 lb. of V; in practice 2.5-2.7 lbs. of $FeSO_4$ are required. The soln. is agitated with air and the $FeSO_4$ soln. pumped in at the center of the steel tanks with cone-shaped bottoms. The $FeSO_4$ soln. is made up of 2.5-4 tons of H_2O to 1 ton of $FeSO_4$, and 50 lbs. of soda added. After adding the calcd. amt. of $FeSO_4$, the ppt. is agitated for 1 hr. and then a sample drawn, filtered and filtrate acidified with H_2SO_4 and tested with $K_4Fe(CN)_6$. The Fe should be present in decided excess, as 4 to 6 hrs. (with agitation) are necessary to complete the pptn., with a minimum ppt. of Ca. 0.15-0.2 g. V remain unptd. The mixt. is drawn off by gravity to 2 sets of monteius each of 14 tons capacity; air is passed in at 30-40 lbs. pressure and the soln. forced through 2 Kelley presses. It requires 1-1.5 hrs. for a cake 0.5-0.75 in. to form on the filter leaves. This is washed 30 min. with H_2O and then discharged into a hopper. The cake is a slimy, black mud, and is carried out of the hopper by a screw conveyor to a Ruggles-Coles drier fired by oil. The discharge from the drier is granular and brown in color and is shipped to the refinery.

F. W. SMITHER.

Flotation at Inspiration Mine, Arizona. ANON. *Mining Sci. Press* 111, 7-10 (1915).—A description of the equipment and methods of flotation exptd. with and used in actual practice at the above mine. A flow sheet is appended. L. A. TOUZALIN.

Arizona Copper Co.'s Dorr thickener. DAVID COLE. *Eng. Mining J.* 100, 132-4 (1915).—An illustrated description of the largest Dorr thickener ever constructed. It is 130 ft. in diam. and is used with entire success to recover water from the tailings of the concg. mill.

E. J. C.

Recovery of mercury from amalgamation tailing, Buffalo Mines, Cobalt. E. B. THORNHILL. *Bull. Am. Inst. Mining Eng.* 1915, 1653-7; *Mining Sci. Press* 111, 211-2 (1915); see C. A. 9, 1740.

E. J. C.

Some properties of thallium-lead alloys. LUIGI ROLLA. Univ. Genoa. *Gazz. chim. ital.* 45, I, 185-91 (1915).—Rurnakow (*Z. anorg. Chem.* 52, 430; 64, 149; 83, 200; 88, 109) showed that in some cases a max. p. on the fusion diagram of a binary system does not correspond to a particular point on the curve of physical properties. Thus in the system Pb-Tl thermal analysis and the micrographic method have shown the presence of an α phase (up to 6.5% Pb) that has the cryst. form of Tl and a β -phase (24.7-100% Pb) that crystallizes in octahedra of the regular system. This branch of the thermal curve rises quickly to the max. which does not represent a simple stoichiometric ratio of Pb and Tl. This abnormal behavior has caused R. to study the physical properties of this alloy and especially the β -phase. In its thermoelec. properties the β -phase is abnormal. It is formed from the components without any change in vol. It is exothermic which argues for the possibility of the formation of true chem. compds. in nonstoichiometric proportions. That is, such a compd. would have

continually varying properties like a soln. R. points out the importance of the definition in these cases and suggests the extension of the ideas of Tammann (*C. A.* 8, 2091).

E. J. WITZEMANN.

Sound steel ingots. ROBERT A. HADFIELD AND GEORGE K. BURGESS. *Engineering* 99, 538-43(1915); see *C. A.* 9, 778, 1168. W. T. HALL.

Sound steel for rails and structural purposes. ROBERT A. HADFIELD. *J. Frank. Inst.* 99, 663-80(1915); see *C. A.* 9, 778, 1168. W. T. HALL.

Heat treatment of low-carbon steel. JOHN LUND. Ordnance Dept. U. S. Army. *Am. Machinist* 42, 505-6(1915).—To show how the microscope enables one to tell very closely what the heat treatment of a steel has been, photomicrographs of a steel containing 0.39% C, 0.28% Si, 0.05% S, 0.04% P and 0.83% Mn are shown both before and after various heat treatments. W. T. HALL.

The change in the elasticity of a mild steel wire with current and external heating. H. L. DODGE. *Phys. Rev.* 5, 373-84(1915).—The wire studied contained 0.06 Si, 0.06 S, 0.11 P, 0.74 Mn, 0.16 C and 98.88% Fe. At first the specimen showed very erratic changes in elasticity on being heated but by continual heating and stretching it was brought to a steady elastic state in which Young's modulus becomes a function of the temp. This was secured first for a temp. range of 20-300° and later up to 475°. Continued heating and stretching gradually increased the modulus but, except for this small and gradual increase, the modulus of the wire was independent of its history, the thermal route by which the temp. was reached having no effect. Heating by an elec. current had no effect other than that of changing the temp. The Young's modulus $\times 10^{-1}$ dynes per sq. cm. was 19.3 at 20° and decreased quite steadily until it reached the value 18.0 at 300°. At 475° the value had decreased to 13.8. W. T. H.

Shell manufacture in a general engineering plant. ANON. *Engineering* 99, 685-6(1915).—The shells are received at the plant in the form of rough forgings. The operations of milling and boring, the heat treatment, the final assembly and the method of testing are described. W. T. H.

The detection of burning in steel. J. E. STEAD. *Engineering* 99, 714-5(1915).—A paper read before the Iron and Steel Inst. The burning of steel, or heating to a temp. such that the steel cannot be rolled or forged without breaking, is coincident with incipient fusion. The part of the metal which melts first is that part which solidified last and is usually rich in P. It is sometimes hard to tell whether the steel is burnt or is merely red-short. It was formerly thought that O from the air caused the trouble but this is not true; the oxide found between the crystals after the metal has broken up is caused by the rush of air which enters the open fissures. Burnt steel can readily be detected when the metal has cooled down for the phosphorized portions are located either in globules or as an envelope around the crystals. If burnt steel is allowed to cool thoroughly and is then reheated to the proper temp., the metal becomes suitable for use. To det. whether a sample is burnt or merely red-short, it is necessary to select a portion of the metal which is free from cracks and etch a polished section with the CuCl_2 soln. to be described in the following abstract. If the metal is free from globular specks, rich in P, the metal is red-short; otherwise it is burnt. W. T. H.

Iron, carbon and phosphorus. J. L. STEAD. *Engineering* 99, 569-72, 611-3, 637-41(1915); illus.—A paper read before the Iron and Steel Inst. It contains a review of all the recent work on the subject and a bibliography of 58 articles together with a statement of exptl. evidence which helps to explain the behavior of P in Fe alloys. A new etching agent is described; it is composed of 10 g. CuCl_2 , 40 g. MgCl_2 , 20 cc. HCl and alc. to make one liter. A thin layer of this liquid is poured upon the polished specimen and allowed to remain there about 1 min. It is not permissible to immerse

the specimen in the etching liquid. The liquid is shaken off the metal and the process is repeated as many times as seems necessary. The surface of the metal is then washed with a little hot water and with CH_3OH which is shaken off and the remainder allowed to evaporate. Cu is deposited first on the portion of the metal containing the least P; the reaction is so sensitive that differences of less than 0.01% can be detected and all irregularities in the distribution of P in wrought Fe or steel can be detected. This behavior, however, is not peculiar to P alone, as it will be shown by any other metal or nonmetal of eutectiferous nature which tends to form conjugate solutions that separate into parts containing different amounts of the element. The reagent is extremely valuable for detecting local differences in the chemical composition of a material. When a large mass of an alloy containing Fe, C and P solidifies, Fe-C separates and, if given opportunity, decomposes somewhat into Fe and graphite before the Fe-C-P eutectic solidifies. This causes considerable internal pressure which tends to squeeze out the still molten Fe-C-P eutectic. In this way is explained the formation of blast furnace *bears* in which the greater part of the P has been eliminated and the residual P is present as uniformly diffused solid solution. The ghost lines so often found in ship and boiler plate have been reproduced synthetically from soft Fe and powdered Fe-C-P eutectic. These ghost lines are evidently composed of material which is richer in P than the surrounding portions. Such parts are the last to carburize on reheating and the first to give up C on cooling. When a C-steel casting contains parts that are richer in P than other parts and the steel is reheated to refine it, the parts richer in P will usually tend to form small crystals and the lower the P content the larger will be the crystals. This is because the primary crystallites, during their development in the more phosphorized steel, are purer than the remaining liquid which precedes them in the mold. The liquid, as these crystallites form, becomes more concentrated and its freezing point is lowered and admits the growth of more new crystallites beyond the impure liquid and these also eventually become surrounded by liquid of lower freezing point than that of the primary crystallites beyond them. This process is repeated again and again until finally the whole mass is solid. When the P content is low, the primary crystallites continue to grow unchecked for a longer distance and larger crystals result. As a general rule, the distribution of P in wrought Fe and in steel is likely to be far from uniform.

W. T. HALL.

The action of dilute solutions of acids, alkalies and salts upon certain metals. A. J. HALE AND H. S. FOSTER. *J. Soc. Chem. Ind.* 34, 464(1915).—Cleaned and polished pieces of metal 1 sq. dm. in size were immersed for 7 days in 0.5 l. of solution renewed every day, for 28 days in 1 l. not renewed, and for 4 hrs. in 0.2 N acid and the loss in weight determined. The metals studied were commercial Zn, cast Fe, wrought Fe, Al, Pb, Cu, Sn, and Ni; the solvents tested were dilute solutions of HNO_3 , HCl , H_2SO_4 , MgCl_2 , NaOH , CaCl_2 , NaCl , NH_4OH and Na_2CO_3 .

W. T. H.

The preparation of metal specimens for metallographic tests. ANON. *Metal. Chem. Eng.* 13, 400-1(1915).—A description of the Wysor combined grinding and polishing machine which can be obtained from Eimer and Amend.

W. T. H.

German silver. R. A. WOOD. *Metal Ind.* 13, 229-32, 322-3(1915).—A general description of the melting, casting and rolling of this alloy. In England it is now called nickel silver.

Heat treatment of copper and brass. CARLE R. HAYWARD. *Metal Ind.* 13, 275-7(1915); illus.—A general descriptive article. W. T. H.

Fatigue of copper alloys. ERNST JONSON. *Metal Ind.* 13, 283-4(1915).—A report of some expts. instigated by the failure of some material used in the Catskill water supply of New York. The results thus far obtained indicate that prolonged excessive stress does not injure metal when it is protected from corrosion while under stress. Corrosion does not generally injure the metal when unaccompanied by excessive stress. Corrosion accompanied by prolonged stress less than 20,000 lb. per sq. in. does not generally injure the metal. Corrosion by ammonia accompanied by a prolonged stress of 20,000 lb. per sq. in. or more causes cracking similar to season cracking. These results apply to Mn-bronze, Muntz metal and gun metal. No Cu alloy has yet been found to which they do not apply. The ammonia test is used as an accelerated corrosion test. Since all Cu alloys in practical use are exposed to various corrosive agents, cracks are likely to develop whenever such alloys are permanently stressed over 20,000 lb. per sq. in. This stress should be regarded as the practical ultimate strength of Cu alloys in general. Cu alloys should not be used in cases where the stress is indeterminate. They should not be used for important bolts when there is the least occasion for drawing them up very tight. W. T. H.

Are the deformation lines in manganese steel twins or slip bands? H. M. HOWE AND A. G. LEVY. *Bull. Am. Inst. Mining Eng.* 1915, 1467-8.—In a former paper (*C. A.* 9, 1165) it was argued that these deformation lines were slip bands; it is now suggested that the appearance of the polished specimens may be due to a combination of slip bands and twins of 2 orders of magnitude. In the former paper, a reason for the commercial value of Mn-steel was sought in the ease with which it "amorphizes." This is shown by expts. with Brinell hardness; if the load is applied all at once, in the usual way, and the values thus found are compared with those obtained by applying the load gradually, there is nearly 20% increase in the latter case. With American ingot iron, representing nearly pure ferrite, an increase of 37% was obtained but with an eutectoid steel, representing nearly pure pearlite, no such increase was noticed. E. E. BUGBEE.

The superficial deformation of steel quenched from temperatures that are not very high. B. BOGIRCH. *Compt. rend.* 160, 768-71(1915).—The phenomenon in question was first noticed by Zschokke in 1910. The steel used in these new expts. contained 0.11% C, 0.035% Si, 0.014% P and 0.22% Mn. Similar results can probably be obtained with any soft steel. The specimens used were $4 \times 4 \times 1$ cm. in size with a perfectly flat, polished surface. They were heated in a metallic bath for 1.5 hr., the temp. being kept constant during the last 30 min. After the heating, the specimen was at once plunged in water at the lab. temp. in such a way that the surface was wet last. Before the initial polishing of the specimen, it was annealed at 750-800° for 15 min. and cooled slowly. When the sample has been heated to between 225 and 350°, quenching produces a peculiar appearance to the polished surface. Ridges start from the sides of the specimen and tend to unite at a central point which does not, as a rule, coincide with the geometric center. Quenching from a temp. of 215-220° causes the first appearance of such deformation. When quenched from a slightly higher temp., the ridges are transformed into larger bands which are unequally inclined toward the surface of the specimen. At 250-260° secondary centers appear and the bands begin to disappear; at about 300° a confused mass of elevations appears. Above 300° the contour of these elevations begins to disappear and at 350-360° the disappearance is complete. The phenomenon depends upon a number of other factors beside the original temp. If the temp. of the quenching bath is raised, the range of temps. which causes such deformation diminishes; no deformation is obtained by quenching in boiling

water. At each temp. of quenching a special type of deformation corresponds if the above conditions are followed; but, by varying the duration of the heating, any desired type of deformation can be obtained. When once quenched, the metal loses the property of being deformed in this way and it is necessary to anneal before trying another expt. As the size of the surface of the specimen diminishes, the thickness being kept the same, the temp. interval in which the deformation can be caused diminishes and when the surface is only 1 cm. square, the tendency disappears entirely. W. T. H.

Change in density of mild steel strained by compression beyond the yield-point. F. C. LEA AND W. N. THOMAS. *Engineering* 100, 1-3(1915).—Specimens 1.25 in. long and 0.75 in. in diameter were turned from mild steel rolled bars and loaded axially in a 100-ton Riehle testing machine. Before applying any load, the d. of the metal was detd. carefully. The results of a series of expts. show that when steel is stressed below the yield-point the d. increases; when stressed to just a little beyond the yield point the d. is the same as at the start and when stressed far beyond the yield point, the d. becomes less than its original value. If the over-strained sample is allowed to rest, the tendency is to revert back to the original d. As explanation, it is suggested that overstrain probably produces an amorphous form of the material which is less dense than the crystalline form; this amorphous form tends to resume the crystalline form and thus to become more dense in the case of overstrained material. The return to normal d. in the case of overstrained materials can be hastened by heating in boiling water. W. T. H.

The corrosion of iron in aqueous solutions of inorganic salts. J. N. FRIEND AND PETER C. BARNETT. *Chem. Trade J.* 56, 435-6(1915).—Expts. were performed with solns. of $Al_2(SO_4)_3$, $(NH_4)_2SO_4$, $BaCl_2$, $FeSO_4$, $MgCl_2$, $MgSO_4$, $MnSO_4$, KCl , KNO_3 , K_2SO_4 , $NaCl$, $NaNO_3$ and Na_2SO_4 . As a general rule, the corrosive power of the concd. solns. was found to be less than that of pure water. As the temp. rises, the rate of corrosion increases rapidly but, with the exception of $(NH_4)_2SO_4$ solns., the corrosive power does not increase as rapidly as does that of pure H_2O . Probably for every concn. there is some temp. (which in some cases is below 0°) at which the corrosive power of the soln. is equal to that of pure H_2O . Below this temp. the soln. will have greater corrosive power than that of H_2O and above it less. The more dil. the soln. the higher the temp. at which the corrosive power is equal to that of water, and for this reason very small amts. of impurity may cause increased corrosion of boilers. W. T. HALL.

The removal of rust by means of chemical reagents. J. NEWTON FRIEND AND C. W. MARSHALL. *Chem. Trade J.* 56, 436(1915).—It has been claimed that dil. solns. of Na citrate will loosen rust without dissolving any Fe. Expts. with 1, 2, 5, 10 and 20% solns. show that such solns. are not suitable media for the quant. removal of rust. They are also very slow in their action. Solns. of H_3BO_3 of 0.5, 1.0, 1.5, 2.0 and 3.5% were found to clean Fe, the 3.5% soln. (which is satd.) acting the most rapidly. When the rust is once removed the Fe dissolves very slowly in such soln. but the loss is greater than when the rust is removed mechanically. No other reagent was found as useful as the boric acid. W. T. HALL.

The relative corrodibilities of gray cast iron and steel. J. N. FRIEND AND G. W. MARSHALL. *Gas World* 62, 579(1915); cf. *C. A.* 9, 1893.—A mild open-hearth steel analyzing: C 0.21, Si 0.013, Mn 0.49, S 0.026, P 0.053%, and a gray cast Fe analyzing: graphite C 2.75, combined C 0.61, Si 1.72, Mn 0.75, S 0.085, P 1.06%, were used in the test. Tap H_2O and 3% NaCl soln. were used and alternate wet and dry tests, alternate wet and dry and hot and cold tests, alternate hot and cold tests and acid tests were made. *Conclusions:* (1) In the alternate wet and dry tests, whether carried out at room temp. or alternately heated and cooled, the

cast Fe usually had the decided advantage. (2) Complete immersion of the metals in H_2O does not give quite the same results as the alternate wet and dry tests; there is little difference between the Fe and the steel, but if any advantage it appears to lean towards the steel. (3) The cast Fe appears to have a slight advantage over the steel in salt H_2O . (4) In acid solns. the cast Fe was very badly attacked, the steel proving in comparison highly resistant. The variation of the results with time and conc. of acid (H_2SO_4 0.05, 0.5, 5, 10, and 20%) is noteworthy, constituting a remarkable testimony, not merely to the uselessness, but to the actually misleading nature of acid acceleration tests, when used as a rapid means of detg. the general corrodibility of Fe and steel. It is pointed out that no simple answer can be given as to whether cast Fe or steel is the more corrodible unless full details are given as to the nature of the corroding media. The results indicate that the relative corrodibilities of cast Fe and steel bear much the same relation to one another at the present time as in earlier years, despite the alteration in methods of manufacture. F. W. SMITHER.

Freezing point diagram of silver-arsenic alloys. W. HEIKE AND A. LEROUX. Freiberg. *Z. anorg. allgem. Chem.* 92, 119-26(1915).—The components were sealed up in porcelain or "siloxide" flasks; in the bottom of each was a reëntrant tube in which was placed a thermoelement. With mixts. rich in As the flasks were placed inside of porcelain tubes filled with sand and closed at the top. Arsenic melts at 814.5° ; the addition of Ag lowers the m. p. to the eutectic at 540° and 25.1 at. % As; no mixed crystals are formed in this region. On addition of As to Ag, and α -mixed cryst. is the primary solid phase until a temp. of 595° is reached, at which temp. a β -mixed cryst. becomes the primary phase. The satd. α -mixed cryst. contains 6.9 at. % As at 595° , the β -cryst. 10.5 at. %; the latter breaks up into α -cryst. and As at 374° . A marked tendency toward undercooling was noticed. GEORGE W. MOREY.

Hardness test on rough cast metals. A. PORTEVIN. *Rev. métal.* 12, 95-100(1915); cf. *C. A.* 9, 1596.—The Brinell hardness test when applied to certain rough cast metals and alloys gives extremely irregular imprints. P. has applied this test to single grains in certain metals and alloys and also to grains that are similarly oriented. By prolonging the time of cooling sufficiently, large enough crystals can be formed for this purpose. In all cases the polished surface of the metal was etched with $FeCl_3$ or $(NH_4)_2S_2O_8$, so that the change in the surface could be easily observed. The errors in measurement of imprints made by a steel sphere of 10 mm. diam. under a pressure of 500 kg. upon single crystals in the following cases were: (1) Cu containing 0.5% V 0.34 mm.; (2) Cu containing 0.75% Al 0.32 mm. and 0.08 mm.; (3) Cu-Al alloy (2.16% Al) 1.01 mm. error where the mean diam. was 3.45 mm. or 29%; (4) Cu-Sn alloy (16% Sn) with pressure of 250 kg. 0.11 mm.; (5) Sb with pressure of 250 kg., *oval* impressions were obtained. Measurements upon crystals similarly oriented using a steel sphere of 10 mm. diam. under a pressure of 500 kg. gave the following results: (1) brass (Cu 70, Zn 30%) mean error of 0.30 mm.; (2) brass (Cu 57, Zn 33%) 0.10 mm.; (3) Zn, pressure 1000 kg., the imprints obtained had an *oval* form, the minimum diam. being in the direction of the longer crystal axis. L. T. FAIRHALL.

Hardening of small steel pieces. ANON. *Elektrochem. Z.* 22, 66(1915).—An app. for quenching steel parts of different kinds is described. For small pieces of complicated design having thin parts, a water bath covered with oil is recommended. This prevents the thin parts from cooling too rapidly and so causing the pieces to crack.

W. E. RUDER.

Persistent fragility in steel. A. PORTEVIN AND V. BERNARD. *Rev. métal.* 12, I, 155-60(1915).—A piece of steel that had been broken in use showed signs of persistent fragility, i. e., heat treatment failed to increase its resistance to shock, indicating that fragility in the metal was due to something other than simple granulation. Careful

metallographic exam. clearly showed that the fragility was due to a network of very small holes or gaps. This network enclosed large ferrite crystals, constituting an enclosure in which cohesion was very feeble and accounted for the fact that heat treatment failed to obviate fragility in the metal.

L. T. FAIRHALL.

Cast irons containing phosphorus. F. CARNEVALI. *Turin. Rass. min.* 39, 21-4(1913).—Castings made of the gray cast iron containing P which is commonly used for such purposes are much harder and more brittle when they are reheated at 1000° than those reheated at 800°. Bars 40 mm. in diameter were cast in molds of perfectly dry earth and after they were completely cold, 1 group was analyzed and tested directly while 2 other groups were first heated 3 hrs. in a Heraeus furnace at 800 and 1000°, resp. (the temp. being slowly and uniformly raised during the course of about 1 hr.) and then slowly cooled (about 1.5 hrs. from 1000 to 500°). The following are the results obtained for the 3 groups, resp.: Total C, 2.94, 2.94, 2.93; graphite C, 2.52, 2.81, 2.54; Si, 2.58, 2.57, 2.58; Mn, 0.85, 0.85, 0.85; P, 1.35, 1.33, 1.34; S, 0.09, 0.09, 0.08%. Brittleness test on a Charpy test bar: angle of rebound, 80, 79, 80°; fracturing work, 1.75, 2.73, 1.75 kg. Brinnell hardness, 1000 kg., 10 mm. balls: 189, 144, 178. Microscopical exam. confirms the results of chem. analyses; the bars reheated at 1000° differ markedly in structure from those heated at 800° and resemble more those which have not been reheated at all; they show numerous pearlite islands occurring only at the periphery of the light masses containing P, while in the bars reheated at 800° the islands of Fe₃P are scattered in a mass consisting of ferrite with numerous laminas of graphite but only a few small pearlite islands.

CHAS. A. ROUILLER.

Die casting of white alloys. J. C. WORK. *School of Mines Quart.* 36, 48-50 (1914).—Casting small parts of automobile engines that can be fitted together without machining can only be effected by applying pressure at the time of casting, but without pressure, accuracy to within 0.002 in. has been attained. The precise compn. of the white metal alloy is not of such importance as the vendors of secret formulas pretend. The die must be of the best grade of gray cast Fe. The temp. of the mold, and that of the metal at the time of pouring are the important points, and require experience. Spray plugs for carburettors made in this manner developed, when used with gasoline, a white deposit, apparently ZnO, which in a short time clogged the orifice. So far as expts. went, the workers were unable to make alloy containing enough Al to prevent this defect.

Ger., 282,894, Oct. 18, 1913. GEHR. SEYBOTH, CHEM. FABRIK. Filtering metals in a molten state through materials of varying permeability. In order to free metals from the oxides formed in fusing them, loose or formed materials, of varying coarseness, some of which are unchanged in the heat and some of which are decomposed thereby, are placed at the bottom of the fusion vessel. The metals are thereby deoxidized and thoroughly filtered. Of especial porosity are those additions which lose, in the heat, a portion of their constituents by volatilization or combination with the metals. These are employed in combination with other materials, such as limestone, magnesite, dolomite, alkali carbonates, quartz, sand, rock crystals, feldspar, and the like. The lowest layer consists preferably of finely ground clay or feldspar, the middle layer of coarsely ground magnesite or feldspar with limestone and coal, the upper layer of coarse sifted sand. At a high temp. the magnesite becomes porous by loss of CO_2 , and the liquid metal flowing through the coarse sand flows through the MgO filter, and finally through the clay or feldspar filter; by employing feldspar with limestone and coal in the middle layer, the limestone, by loss of CO_2 and the feldspar by the action of the Ca(OH)_2 , formed, become porous, with sepn. of the corresponding alkali compds, which with coal form the corresponding alkali metals and CO_2 , whereby the O dissolved in the metals are reduced.

Ger., 282,899, Dec. 20, 1910. E. FRITSCH. Coating with aluminium, with the aid of a mechanical mixt. of Al powder and a welding powder (Zn), combined by means of a binder to a mass which may be spread upon the surface to be coated. The coated articles are then subjected to a temp. corresponding to the m. p. of the welding constituent.

Norw., 24,635, July 5, 1911. AKTIEBOLAGET "ELEKTROMETALL." In a process of reducing ores, a catalyzer especially prepared for the purpose is added to the charge, and consists of metallic Fe or Fe oxide of lower degree of oxidation than that of the ore under treatment. Cymarin, the active principle of *Apocynum cannabinum*. A. WINDAUS AND L. HERMANS. Univ. Innsbruck. *Ber.* 48, 979-90(1915).—The cymarin (a), prepd. by Bayer & Co. (*C. A.* 7, 1587), seps. from aq. MeOH in prisms, foams $130-8^\circ$ (depending on the rate of heating), exceedingly bitter, seps. from acetone in prisms, sinters 120° , foams a few degrees higher (the foaming is due to loss of solvent of crystn.), $[\alpha]_D^{20} 23.5^\circ$

in CHCl_3 , gives the Lieberman cholesterol test with $\text{H}_2\text{SO}_4\text{-Ac}_2\text{O}$, couples with PhN_2Cl and NaOH with formation of a deep violet soln. changing to brick-red on acidification with AcOH , indifferent towards FeCl_3 , faintly reduces $\text{NH}_3\text{-AgNO}_3$, gives the Legal test with $\text{Na}_2\text{Fe}(\text{NO})(\text{CN})_6$ and the Keller-Kiliani digitoxin test with AcOH and H_2SO_4 containing Fe . Titration with hot alkali indicates an equiv. wt. of 581; the air-dried product crystd. from MeOH contains 10.7% MeO , 0.5 of which is present as MeOH of crystn. These data and elementary analyses agree with the formulas $\text{C}_{31}\text{H}_{48}\text{O}_{10}\cdot 0.25\text{-H}_2\text{O}$ or $\text{C}_{30}\text{H}_{46}\text{O}_{10}$; preference is given to the 1st. On drying *in vacuo* at 95° , it loses 5.7% in wt. and its comp. then corresponds to $\text{C}_{30}\text{H}_{44}\text{O}_9$. The product from aq. acetone contains 5.2% MeO and corresponds to $\text{C}_{30}\text{H}_{46}\text{O}_{10}\cdot 0.5\text{H}_2\text{O}$; on drying *in vacuo* it loses 6.45% in wt. and then has the comp. $\text{C}_{30}\text{H}_{44}\text{O}_9$. Const. titration values are obtained only when 0.1 g. of the air-dried product from MeOH in 10 cc. alc. is boiled 45 min. with 10 cc. of 0.1 N NaOH ; on short boiling less alkali is neutralized while long boiling and the use of a large excess of NaOH produces deep-seated decompn. and neutralization of more alkali. Although (a) is a glucoside, when boiled with acids the sugar is quickly transformed into an insol. tar and escapes detection, but if hydrolyzed with cold HCl (a) gives a "genin" and a sugar. The *cymarigenin* (b), $\text{C}_{22}\text{H}_{30}\text{O}_5\cdot \text{H}_2\text{O}$, contains no MeO , behaves towards alkalies like a lactone, is identical with Moore's apocynamarin, $\text{C}_{22}\text{H}_{30}\text{O}_5\cdot 2\text{H}_2\text{O}$ (C. A. 3, 2962); of its 5 O atoms, besides the 2 in the lactone ring, a 3rd is present as HO and at least 1 of the other 2 is in a $\text{C}:\text{O}$ group. It is insol. in soda and cold KOH , but warm 0.1 N alkali converts it into the salt of a HO acid which easily loses H_2O ; the resulting lactone, however, is not identical but isomeric with (b); probably the HO originally combined with the sugar has now taken part in the lactone formation. (b), obtained in 2 g. yield from 3 g. (a) in 12 cc. alc., 12 cc. H_2O and 6 cc. concd. HCl allowed to stand 5-6 hrs. in the cold, dild. with 3 vols. H_2O and freed from alc. *in vacuo* over H_2SO_4 , seps. from 5 parts MeOH or 10 parts H_2O in pearly rhombic tables, m. about 171° (foaming), depending on the rate of heating, very bitter, gives the Liebermann cholesterol reaction, faintly reduces $\text{NH}_3\text{-AgNO}_3$, gives dyes with diazonium salts, does not react with FeCl_3 , is pharmacologically active, $[\alpha]_D^{20}$ 44.0° in MeOH , gives with BzCl in $\text{C}_6\text{H}_5\text{N}$ a *benzoate*, $\text{C}_{30}\text{H}_{40}\text{O}_7\cdot 0.5\text{H}_2\text{O}$, thin, pearly leaflets from 10 parts MeOH and 3 parts H_2O , m. 230° . *Anhydrocymarigenin*, $\text{C}_{22}\text{H}_{28}\text{O}_4$, from (b) in CHCl_3 treated several hrs. with dry HCl , m. 246° (decompn.). *Isocymarigenin*, (c), $\text{C}_{22}\text{H}_{30}\text{O}_5\cdot 1.5\text{H}_2\text{O}$, from 1 g. (b) in a little MeOH boiled 1 hr. with 50 cc. of 0.1 N alkali, treated with excess of HCl and concd. *in vacuo*, pearly leaflets from dil. AcOH , m. 239° , behaves towards soda and KOH like (b), no longer gives the cholesterol test typically; both it and (b) with hot concd. alkalies give yellow amorphous products and react (as does also (a)) with ketone reagents but the products are difficult to cryst. The filtrate from (b) in the hydrolysis of (a), when extd. 5 times with CHCl_3 , freed of HCl with Ag_2CO_3 , concd. *in vacuo*, repeatedly extd. with boiling Et_2O , the ext. pptd. with petr. ether, the ppt. treated with H_2O , filtered, evapd. and the treatment with Et_2O and petr. ether repeated, yielded the sugar, *cymarose* (d), in fine prisms, m. 88° , needles from acetone, reduces hot Fehling soln., decomps. when evapd. with acids, turning green, then brown, forms no osazone, is oxidized to AcOH , gives the same color reactions as digitoxose (Kiliani, C. A. 8, 2449). Its comp. is $\text{C}_7\text{H}_{14}\text{O}_4$; it contains 1 MeO and is probably digitoxose Me ether. *Cymarinic acid*, $\text{C}_{30}\text{H}_{50}\text{O}_{12}$, from 2 g. (a) heated 45 min. with 50 cc. of 0.1 N KOH over a free flame, cooled, neutralized with 50 cc. of 0.1 N HCl , satd. with NaCl , shaken with 100 cc. CHCl_3 , and the ppt. filtered after 24 hrs., prisms from acetone- H_2O or AcOEt -petr. ether, m. 168° , sol. in cold soda, does not reduce Fehling soln., physiologically inactive, contains 1 MeO , loses 2 H_2O *in vacuo* over H_2SO_4 and 0.5 H_2O more *in vacuo* at 110° , can easily be titrated in alc., gives the Keller-Kiliani digitoxose reaction and the other color reactions of (a), shows no tendency to form a lactone; with acids it forms (c) and (d).

C. A. R.

Relation of cymarín with other cardiac poisons of the vegetable kingdom. A. WINDAUS AND L. HERMANS. Univ. Innsbruck. *Ber.* 48, 991-4(1915); cf. preceding abstr.—A new study of strophanthidin, the hydrolysis product of strophanthin Kombé, has shown that it is identical with cymarigenin, in spite of the apparent differences in the properties of the former, as described by Feist (*Ber.* 33, 2069(1900); cf. also Heffter and Sachs, *C. A.* 6, 1812; Brauns and Closson, *C. A.* 9, 507). They show the same m. p. and behavior towards solvents and reagents, give the same titration values, yield the same benzoate, give with KMnO_4 the same acid (F.'s strophanthic acid), which, however, W. and H. believe to have the comp. $\text{C}_{22}\text{H}_{30}\text{O}_8$; with CH_3N_2 in acetone it gives a *dimethyl ester*, $\text{C}_{24}\text{H}_{34}\text{O}_8$, needles from aq. MeOH, m. 214° . The strophanthin and cymarín differ, therefore, only in that one is a compd. of strophanthobiose Me ether and the other of digitoxose Me ether. Comparison of cymarín with the cardiac poisons of *Digitalis purpurea* and *Antiaris toxicaria* also shows close relationships; digitoxose, thus far identified with certainty only in digitoxin and the components of Kraft's "gitalin," occurs as the Me ether in cymarín, and the hydrolysis products of antiarin and digitoxin are HO lactones like cymarigenin and of very similar comp.; apparently they all contain a very similar C skeleton which is only loaded down to varying degrees with O in the individual compds. There are also certain similarities between cymarigenin and an animal cardiac poison, bufotalin (Wieland and Weil, *C. A.* 8, 347), which is also a HO lactone and gives the cholesterol test. CHAS. A. ROULLER.

Catalytic actions of colloidal metals of the platinum group. XIII. Hydrogenation of ethylene with colloidal platinum. C. PAAL AND ANTON SCHWARZ. Univ. Erlangen. *Ber.* 48, 994-1001(1915); cf. *C. A.* 3, 2455.—The following expts. were carried out with equal vols. of C_2H_4 and H_2 at room temp. under atm. pressure, with colloidal Pt, protected with Na protalbinat, as catalyst. Whereas it was previously found that with 0.05 g. Pd 25 cc. C_2H_4 are quant. reduced in a gas burette in 70 min., with 0.047 and 0.0915 g. Pt in 10 cc. H_2O 160 and 88 min., resp., are required. In expts. in a shaking app., it was found that shaking increases the velocity of reduction and that with fresh colloidal Pt the reduction is also much faster than with Pt preps. which have already been used. The more concd. the colloidal Pt soln. the more rapid is the reduction with equal amts. of Pt, but the velocities are not directly proportional to the concn., increasing much more slowly than the concn. Similarly, with decreasing amts. of Pt the velocity of reduction decreases much more slowly than the amt. of Pt in solns. of the same concn. In other words, within certain limits both the quantity and the concn. of the catalyzer have but a slight influence on the course of the reduction. Pd is somewhat more effective than an equiatomic amt. of Pt. CHAS. A. ROULLER.

Nitration of halogenacylated anilines. EMIL VOTOCEK AND JAN BURDA. Prag. *Ber.* 48, 1002-8(1915).—Nitration of acylated anilines in which the acyl group is derived from strong acids gave only *o*- and *p*-, never *m*-compds., and since PhNH_2 in excess of concd. H_2SO_4 (i. e., present as $\text{PhNH}_2\text{SO}_3\text{H}$) gives much *m*- $\text{H}_2\text{NC}_6\text{H}_4\text{NO}_2$, the chief factor in detg. whether the NO_2 group will enter the *o*- and *p*- or the *m*-position is probably whether the N of the amine is tri- or pentavalent. Thus, $\text{PhNHCOCH}_2\text{Cl}$, m. 135° , best prepd. from ClCH_2COCl and 2 mols. PhNH_2 in C_6H_6 , when introduced into 3 parts of 94% HNO_3 at 7° soon deposits a mixt. of NO_2 compds. which are completely pptd. with ice after a few min. and are sepd. by crystn. from PhMe into the less sol. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NHCOCH}_2\text{Cl}$, m. $185-5.5^\circ$ (Deutsch, *C. A.* 2, 1151, gives 151°), sol. in alc. KOH with yellow color, and the more sol. *o*-nitrochloroacetylaniline, m. $90-3^\circ$, sol. in alc. KOH with red color. Similarly, PhNHCOCHCl_2 , m. $118-21^\circ$, at -2° gave *p*-nitrodichloroacetylaniline, m. $128-30^\circ$, and the *o*-nitro compound, light yellow, m. $78-80^\circ$, sol. in alc. KOH with orange-red color. From PhNHCOCCl_3 , m. $95-7^\circ$, were obtained *p*-nitrotrichloroacetylaniline, m. $146-7^\circ$, sol. in alc. KOH with

yellow color, and the *o*-nitro compound, yellow, m. $70-2^{\circ}$, sol. in alc. KOH with orange-red color. The same results were obtained when the acylanilines were nitrated in cold concd. H_2SO_4 .

CHAS. A. ROUILLER.

Strychnos alkaloids. XXIII. Oxalic acid and an amino acid, $\text{C}_{17}\text{H}_{18}\text{O}_4\text{N}_2$, as cleavage products of strychninolonic acid a. HERMANN LEUCHS AND GEORG SCHWAEBEL. Univ. Berlin. *Ber.* 48, 1009-15 (1915); cf. *C. A.* 8, 2718.—Just as the acid $\text{C}_{22}\text{H}_{34}\text{O}_{10}\text{N}_2$ obtained by oxidation of acetylbrucinolone a yields on cleavage $(\text{CO}_2\text{H})_2$, AcOH and an NH_2 acid (*C. A.* 8, 1427), so 3 g. of the salt $\text{C}_{21}\text{H}_{18}\text{O}_8\text{N}_2\text{Ba} \cdot 2\text{H}_2\text{O}$ (a) obtained in the oxidation of acetylstrychninolone a, when heated 45 min. on the H_2O bath with 30 cc. HBr (d. 1.47), treated with 10 cc. of *N* H_2SO_4 dild. with H_2O , filtered from the BaSO_4 , evapd. to a thick syrup *in vacuo* at a low temp., covered with 50 cc. Et_2O and extd. on the following day twice with the same amt. of Et_2O , gave 0.5 g. $(\text{CO}_2\text{H})_2$. The portion insol. in Et_2O when treated in 15 cc. cold MeOH with 2.5 cc. HBr (d. 1.47) gave 2.35 g., not of the expected NH_2 acid, but of its *methyl ester dihydrobromide* (b), $\text{C}_{17}\text{H}_{18}\text{O}_4\text{N}_2 \cdot 2\text{HBr}$, 3-cornered or trapeze-shaped leaflets with 5-9% H_2O from a mixt. of 30 vols. MeOH and 4 vols. HBr, sinters around 225° and gradually decomp. at higher temps., tastes strongly acid and bitter; on recrystn. from H_2O , MeOH or, best, 150 vols. abs. alc. it loses 1 HBr and seps. as the *monohydrobromide*, rectangular, faintly greenish prisms, m. $258-60^{\circ}$ on slow, 278° on rapid heating, seps. from H_2O in 6-sided elongated tablets. From 1 g. of the above HBr salts in 10 cc. of 25% aq. NH_3 there is obtained in a short time 0.3 g. of the *amide*, $\text{C}_{17}\text{H}_{19}\text{O}_4\text{N}_3$, flat 6-sided prisms with 1 H_2O from 300 parts H_2O , m. about 280° (decompn.), forms a neutral aq. soln., dissolves in alkalis only on long standing, easily in dil. mineral acids, with difficulty in AcOH; NH_3 repts. it. From 0.17 g. in 6 cc. of 3 *N* HNO_3 is obtained 0.16 g. of the *nitrate*, $\text{C}_{17}\text{H}_{19}\text{O}_4\text{N}_3 \cdot \text{HNO}_3$, pointed octahedrons, hydrolyzed by H_2O . From 1 g. (b) in 10 cc. of H_2O at 20° treated with 50 cc. of cold satd. $\text{Ba}(\text{OH})_2$ is obtained 0.3 g. of a *barium salt*, $(\text{C}_{17}\text{H}_{17}\text{O}_4\text{N}_2)_2\text{Ba} \cdot 4\text{H}_2\text{O}$, sepg. from 200 cc. H_2O and 50 cc. alc. in needles, sol. in H_2O with neutral reaction. From 3 g. (a) treated as above with HCl instead of HBr are obtained $(\text{CO}_2\text{H})_2$ and 1.2 g. of the *amino acid hydrochloride*, $\text{C}_{17}\text{H}_{18}\text{O}_4\text{N}_2 \cdot \text{HCl}$, massive 6-sided short columns from 20 cc. MeOH or faintly greenish rectangular tables from H_2O , loses 0.66% in wt. at 100° and 12 mm. over P_2O_5 , decomp. about 278° , easily sol. in dil. HCl, gives no ppt. with NH_3 or $\text{Ba}(\text{OH})_2$ but yields (b) with HBr in MeOH; with PhNCO and dil. alkali is formed a *ureido acid* pptd. by acids in amorphous form easily sol. in soda. *Sulfate*, $\text{C}_{17}\text{H}_{18}\text{O}_4\text{N}_2 \cdot \text{H}_2\text{SO}_4$, in 1.5 g. yield from 3 g. (a) treated as above with HBr, then with 7 cc. of 5 *N* H_2SO_4 concd. *in vacuo*, freed from $(\text{CO}_2\text{H})_2$ and crystd. from alc. and then from 15 cc. of 2.5 *N* H_2SO_4 + 45 cc. alc., 4- or 6-sided leaflets with 1 H_2O , gradually decomp. on heating, easily sol. in H_2O but soon goes over into less sol. needles still containing H_2SO_4 , gives no ppt. with NH_3 , forms (b) with HBr in MeOH.

CHAS. A. ROUILLER.

Spiranes. VI. α -Halogenation of optically active ketones. HERMANN LEUCHS. Univ. Berlin. *Ber.* 48, 1015-20 (1915); cf. *C. A.* 7, 3330; 9, 82.—*dl*- β -Chloro- β -(benzyl-*o*-carboxy)- α -hydrindone, (a), obtained in 1.95 g. yield from 2 g. of the unsubstituted $\text{C}_{17}\text{H}_{14}\text{O}_3$ (b) added to 40 cc. CHCl_3 containing somewhat more than the calcd. amt. of Cl (0.52 g.), evapd. *in vacuo* and crystd. from C_6H_6 , long rectangular prisms, m. $146-7^{\circ}$, losing HCl and passing over into the lactone, sol. in 100 parts cold C_6H_6 , gives AgCl quite rapidly with AgNO_3 on boiling alc., sol. in aq. soda and NH_3 but at once seps. as the lactone. Approx. 2% solns. of the *d*-form of (b) in CHCl_3 were prepd. from the brucine salt as previously described (*C. A.* 7, 3331), the operation requiring 0.5-1.0 hr.; after clarification with Na_2SO_4 they showed an av. $[\alpha]_D^{20}$ of 69° , the highest observed value being 76° . Four such solns. (from 71 g. salt) were treated with an excess of Cl in CHCl_3 , and evapd. *in vacuo*, giving 30 g. residue which on recrystn. from 150 cc.

AcOH yielded 21 g. showing in 3.6% AcOH soln. α 13.4° (the filtrate was inactive and on concn. yielded 8.6 g. *dl*-(a)). Expt. having shown that the activity was not diminished by heating 0.5 hr. at 100° in AcOH or boiling a few min., the 21 g. above was dissolved in 150 cc. AcOH at 100° and allowed to cryst., giving 13 g. (the filtrate was again inactive); another crystn. from 150 cc. and one from 50 cc. yielded 1.7 g. of prisms with asbestos luster, striated owing to twin formation, m. 171–3° (gas evolution) (the filtrate in the final crystn. was strongly *d*-rotatory, indicating that the purification was complete), $[\alpha]_D^{20}$ 130° in AcOH, sol. in aq. soda but soon seps. as the lactone. Concn. of the final filtrate yielded 0.9 g. more of this *d*-form of (a), making the total yield 2.6 g. while that present in the original 21 g., calcd. from its activity, should have been only 2.2 g. This too high yield may be due to varying values of α and 0.1–0.2 g. is to be ascribed to a resolution of the *dl*-form, for on recrystn. there was obtained at a certain stage, as a result of supersatn., a *l*-rotatory filtrate which, from its activity, must have contained 0.1–0.2 g. of the *l*-form in excess; from this soln. was obtained as above 0.15 g. of the *l*-form, m. 173°, $[\alpha]_D^{20}$ 129.4°; mixed with an equal part of the *d*-form, it m. 146–7°. *l*-Dihydroisocoumarinhydrindone-3,2-spirane, in 0.43 g. yield from 0.5 g. *d*-(a) treated with soda and filtered after 1 hr., needles, m. 177°, $[\alpha]_D^{20}$ –65° in C₆H₆ (the values previously found were 176° and –65.3°, resp.). *d*-Form, similarly obtained from the *l*-(a), m. 177°, and when mixed with an equal part of the *d*-form shows the m. p., 154°, of the *dl*-lactone.

J. H. MOORE.

Trichloroacrylic acid and some of its derivatives. II. J. BÖHSEKEN AND J. F. CARRIÈRE. Delft. *Rec. trav. chim.* 34, 179–86(1915); cf. C. A. 7, 3490.—Although the m. p. of CCl₃.CClCO₂H (a) is nearly 73° it forms 2 liquid layers with H₂O at room temp. It seemed that the system H₂O + (a) might be an example of the H₂O + PhOH class and it was studied for that reason. The (a) was prepd. as described before by heating hexachloropropene at 130° with 90% H₂SO₄, except that a little Al₂(SO₄)₃ is now added to the mixt. The reaction mixt. is poured into a little ice and forms 2 liquid layers, of which the lower solidifies at temps. below 14°. After recrystg. several times from CS₂ the acid is placed in a desiccator over NaOH until free from CS₂. This pure acid b₁₀ 133°, but the liquid solidifies only partly and in H₂O it does not give 2 layers at once, but a solid which m. 40°. The acid thus treated probably contains some anhydride, which m. 39–40° and is insol. in H₂O (Fritsch, *Ann.* 297, 317 (1897)). No change in elec. cond. could be shown, which indicates that hydration probably takes place more rapidly than soln., which is in accordance with previous observations of B., *et al.* (C. A. 6, 1610) on other anhydrides of strong acids. (a) b₇₀₀ 221–3° and solidifies slowly to a waxy mass. In C₆H₆ solns. at less than 1% concns. the mol. wt. is double; in PhNO₂ 58% is dimol. Aq. solns. (≈0.09 *N*) are nearly completely dissociated but this diminishes rapidly with increase in concn. For the system H₂O + (a) the 1st 3 points on the f. p. curve were detd. with a Beckmann thermometer: 99.86 mol. % H₂O, f. p. –0.267°; 99.79%, –0.357°; 99.49%, 2.8°. The following points were detd. by fusing the mixt. in sealed tubes and detg. the f. p. in an illuminated thermostat: 99.20 mol. % H₂O, 37.2°; 98.85%, 46.6°; 97.68%, 54.1°; 95.98%, 57.8°; 93.61%, 60.0°; 93.58%, 60.85°; 92.43%, 60.85°; 87.73%, 53.0°; 86.32%, 46.5°; 84.51%, 19.5°. The following points were detd. by the f. p. method, some in a H₂O bath and some in a Dewar flask: 26.47 mol. %, 60.5°; 41.54%, 54.0°; 51.03%, 42.3°; 58.77%, 32.8°; 62.81%, 26.5°; 66.97%, 20.3°; 68.27%, 17.7°; 70.39%, 14.9°; 72.04%, 12.7°; 73.34%, 11.2°. The following points were identified: f. p. of H₂O, 0°; eutectic for ice + (a).2.5H₂O (liquid I + H₂O: 99.5 mol. % H₂O), –0.6°; critical point of the miscibility 60.85° (≈92.5 mol. % H₂O);

eutectic for liquid (I + II) + (a).2.5 H₂O (84.5 mol. % H₂O) 13.70°; m. p. of (a).2.50 H₂O 19.2° (71.4 mol. % H₂O); eutectic for (a).2.5 H₂O (69.4 mol. % H₂O) 17.0°; f. p. of (a).72.9° (0 mol. % H₂O).

E. J. WITZEMANN.

The nitration of methylurea. H. J. BACKER. Univ. Leyden. *Rec. trav. chim.* 34, 187-203(1915); cf. C. A. 8, 2346.—The behavior of methylurea and ethylurea toward nitrating agents is considered as a striking example of the different influences that Me and Et may exercise on the properties of a compd. Degner and v. Pechmann (*Ber.* 30, 652(1897)) have said that in methylurea the imino NH is nitrated and Thiele and Lachman (*Ann.* 288, 285(1895)) found that in ethylurea the NH₂ is nitrated: i. e., the products are MeN(NO₂)CONH₂, and EtNHCONHNO₂. B., in prepg. the substances for other expts. found that the statements for methylurea are untrue. D. and v. P. treated methylurea in H₂SO₄ with the theoretical amt. of EtNO₂ and obtained methylnitroamine and a methylnitrourea (m. 156-7° (decompn.)). B. nitrated methylurea as above, also by adding HNO₃ to the H₂SO₄ soln. and by adding methylurea nitrate to H₂SO₄ but always got methylnitrourea, decomp. 90-100°, and no methylnitroamine. When the product was dissolved in cold NH₄OH and the soln. acidified methylnitrourea (a) m. 159° (decompn.), seps. This compd. was shown to be α,β -methylnitrourea, by reduction to semicarbazide and by its decomp. action on bases. (a) reduced and condensed with BzH gave benzaldehyde methylsemicarbazide, m. 166°, which with dil. H₂SO₄ gave free methylsemicarbazide (b), m. 118°. This on hydrolysis gave N₂H₄ so that (b) ought to be hydrazinoformmethylamide, NH₂NHCONHMe, and (a) must be NH(NO₂)CONHMe. In order further to prove this N₂H₄ was treated with CO:NMe and gave NH₂NHCONHMe, m. 118°, identical with (b). The constitution of (b) was further proved by the fact that with CH₃Ac₄ (b) gives 3,5-dimethyl-1-methylaminoformylpyrazole: the isomer of (b), NH₂NMeCONH₂, does not give a pyrazole. Hydrolysis by bases is of value in detg. whether one has a primary nitroamine or an alkylnitroamine. The 1st gives NH₂NO₂ which decomp. into N₂O while AcN(NO₂)R gives a monoalkylnitroamine, RNHNO₂. Accordingly the equations would be MeN(NO₂)CONH₂ + 3KOH $\longrightarrow$ MeN(NO₂)K + K₂CO₃ + NH₃ + H₂O or MeNHCONHNO₂ + 2KOH $\longrightarrow$ MeNH₂ + K₂CO₃ + N₂O + H₂O. Since (a) gave N₂O when treated thus, the latter reaction is correct and (a) must be the α,β -deriv. Similar reactions occur with NH₃ thus: MeN(NO₂)CONH₂ + 2NH₃ $\longrightarrow$ MeN(NO₂)-NH₂ + (NH₂)₂CO or MeNHCONHNO₂ + NH₃ $\longrightarrow$ MeNHCONH₂ + N₂O + H₂O. (a) heated with NH₃ gave MeNHCONH₂, showing again that (a) is the α,β -deriv. When the product, m. 90-100° (decompn.) was treated with NH₄OH for purification it gave only about a 50% yield of the α,β -deriv. When treated with KOH and NH₃ it gave methylnitroamine. Quant. decompn. with Ba(OH)₂ showed the presence of 40% of the α,α -methylnitrourea in the crude product. With KOH the crude product liberated N₂O corresponding to 55% of α,β -deriv. It was desirable to prep. α,α -methylnitrourea. Expts. in methylation of nitrourea with MeI, CH₂N₂, and Me₃SO₄ gave poor results. The action of MeNHNO₂ on CONH was found to give condensation products of CONH. Attempts to nitrate α,β -methylacetylurea should have given AcNHCON(NO₂)Me but it was decompd. Its decompn. by HNO₃ is explained thus: (1) AcNHCON(NO₂)Me $\longrightarrow$ AcNH₂ + CO₂ + MeNHNO₂; (2) AcNH₂ + HNO₃ $\longrightarrow$ AcOH + N₂O; (3) MeNHNO₂ + HNO₃ $\longrightarrow$ MeNO₂ + N₂O, since the amt. of N₂O evolved corresponds to these reactions. The compd. sought was not obtained. (a) was obtained thus: 15 g. methylurea nitrate were added gradually to 50 cc. concd. H₂SO₄ at -15° with agitation, in 20 min. In 10 min. more the mixt. was poured on 100 g. ice + 150 g. crystd. Na₂CO₃, filtered with suction, the filtrate was extd. with AcOEt and the ppt. dissolved in it, dried with Na₂SO₄, concd. and crystd.; it m. 90-100°. 4.5 g. of the above product in 6 cc. NH₄OH + 10 cc. H₂O were cooled and treated with

10% H_2SO_4 till Congo paper was turned blue: 1.8 g. or 40% α,β -methylnitrourea, m. 159°, sepd. The latter was reduced electrochem. (cf. Backer, *C. A.* 6; 1608); 40 cc. 5% H_2SO_4 in a tinned Cu cylinder (120 sq. cm. surface) to which 2 g. of the α,β -deriv. were added a little at a time served as the cathode chamber. 10% H_2SO_4 in a porous vessel with a Pb anode completed the app. The whole was packed in ice and electrolyzed at 1.5–2.0 v. for 161 amp. min., nearly neutralized with Na_2CO_3 and treated with BzH as indicated above. Details of the treatment of the α,α - and α,β -derivs. with KOH , NH_4OH and $\text{Ba}(\text{OH})_2$ are given. 3.7 g. MeNCO (from $\text{KOCN} + \text{KMeSO}_4$) added to 2.1 g. N_2H_4 gave 4.7 g. of 4-methylsemicarbazide (b), long, white needles from C_6H_6 , sol. in H_2O , MeOH and EtOH and AcOH , behaves like N_2H_4 toward oxidizing agents; aromatic aldehydes in alc. give well crystd. semicarbazones in calcd. amts. in aq. soln. slightly acid with AcOH . The 4-hydrazinoformmethylamides described below are little sol. in petr. ether, H_2O and Et_2O but are sol. in EtOH and AcOH . Salicylal, $\text{HOCH}_2\text{CH}=\text{CH}:\text{NNHCONHMe}$, nearly colorless needles, decomp. on heating; anisal, needles, m. 175°; piperonal, needles, m. 203–5°; p-nitrobenzal, yellow needles, m. 236° (gas). A careful crystallographic description of 3,5-dimethyl-1-methylaminoformylpyrazole is given.

E. J. WITZEMANN.

The nitration of mixed dihalogen benzenes. A. F. HOLLEMAN with H. P. HEINEKEN, *et al.* Univ. Amsterdam. *Rec. trav. chim.* 34, 204–35 (1915).—In his book (*Einführung von Substituenten in den Benzolkern*) H. deduced from qual. expts. given in the literature that the decreasing order of velocity of substitution, caused by groups already present in the nucleus, for groups that direct para-ortho is $\text{OH} > \text{NH}_2 > \text{halogens} > \text{Me}$. For example, in cresol the influence of OH will predominate over Me in such a way that the substituent that enters the nucleus will place itself *o*- or *p*- to the OH . Recently, Wibaut (*C. A.* 8, 1268) studied the nitration of chlorotoluenes quant. and found that the velocity of substitution caused by the Cl and Me is as 1.475:1. The present paper is a report on the relative velocities caused by the halogens. For this purpose the mixed halogen derivs. $\text{C}_6\text{H}_4\text{XY}$ have been nitrated. These compds. have been very little studied; it is known that some of the *I* derivs. are decompd. by HNO_3 . The mixed *F* derivs. are hardly known at all and the nitration has not yet been studied. I. Nitration of *p*-chlorobromobenzene. *p*- $\text{ClC}_6\text{H}_4\text{Br}$, prepd. by the method of Holleman and van der Linden (*C. A.* 5, 1436), f. 64.6°, n_D^{20} 1.5531. 2,5- $\text{ClBrC}_6\text{H}_3\text{NO}_2$ (a) was prepd. in 2 ways. (1) 52.5 g. *o*- $\text{ClC}_6\text{H}_4\text{NO}_2$ + 1 g. Fe powder + 20 cc. Br_2 was boiled under a condenser in an oil bath until HBr was no longer evolved, when it was poured into H_2O , treated with dil. HCl to remove Fe , dried and (a) recrystd. from EtOH as white crystals, m. 72°, f. 69.7°, n_D^{20} 1.5839. (2) 5 g. 2,5- $\text{Br}_2\text{C}_6\text{H}_3\text{NO}_2$ + 20 cc. 3.9 *N* NH_4OH in sealed tubes for 8 hrs. at 168° gave 4,2- $\text{Br}(\text{NO}_2)\text{C}_6\text{H}_3\text{NH}_2$, m. 111°, which diazotized, etc., according to v. d. L.'s method, gave (a). It was attempted to obtain 5,2- $\text{ClBrC}_6\text{H}_3\text{NO}_2$ (b) by treating *o*- $\text{BrC}_6\text{H}_4\text{NO}_2$ with Cl in the presence of SbCl_5 or FeCl_3 but the complex mixt. obtained could not be sepd. even in several months. 5 g. 2,5- $\text{Cl}_2\text{C}_6\text{H}_3\text{NO}_2$ heated 12 hrs. with 20 cc. NH_4OH at 185° in the sealed tube gave the chloronitroaniline (c), m. 116°, which diazotized, etc., gave (b), m. 70°, n_D^{20} 1.5832. (c) was obtained thus: 28 g. *p*- $\text{ClC}_6\text{H}_4\text{NHAc}$ were added gradually to 140 g. HNO_3 (d. 1.50), decolorized with urea, at -10° ; the mixt. was poured on ice, filtered, etc., and the *Ac* deriv. sapond. to give (c). The m. p. curve for the system (a) + (b) was detd. The course of the curve is unusual since it indicates that the 2 isomers give a continuous series of mixed crystals, with a minimum m. p. It is the 1st case of the kind for isomeric aromatic derivs. The formation of mixed crystals explains why Körner and Mouneyrat and Pouret obtained a mononitrated product from *p*- $\text{ClC}_6\text{H}_4\text{Br}$ (m. 68.6° and 68.2°) which remained unchanged with repeated crystn., for it is now well known that these mixts. cannot be sepd. in this way. The thermal method will not work

for the analysis of this system. 5 g. $p\text{-ClC}_6\text{H}_4\text{Br}$ were added to 25 g. HNO_3 (d. 1.52) at 15° ; after 15 min. the mixt. was poured into H_2O , the NO_2 deriv. recrystd. from EtOH (m. 70°), the EtOH soln. heated 12 hrs. in the sealed tube with excess of $\text{NH}_3\text{-EtOH}$ at 170° , poured into H_2O and crystd. from EtOH; 4,2,1-bromonitroaniline, m. $111\text{--}2^\circ$, sepd., which shows that (a) was present in the nitration products. The mother liquors were evapd. to dryness, heated over a bare flame to sublime the NH_4 salts, dissolved in H_2O , treated with $\text{Cl-H}_2\text{O} + \text{CS}_2$ and the brown color obtained proved that (b) was also present because Br in (b) is displaced in this but not that in (a). Since it is certain that in (a) only the Cl is mobile and in (b) only the Br, by heating a known wt. of the mixt. with MeONa a mixt. of NH_4Cl and NH_4Br would be obtained having the same mol. ratio as the original (a) and (b). The NH_4 salts were analyzed by pptg. as $\text{AgCl} + \text{AgBr}$ and weighing. The ppt. was treated with Cl and weighed again and from these data the amts. of each were calcd. 2 g. $p\text{-ClC}_6\text{H}_4\text{Br}$ added slowly to 28 cc. HNO_3 (d. 1.50), decolorized with urea, + 20 cc. ordinary HNO_3 at 0° to 3° was poured on ice; the product washed with H_2O and distd. *in vacuo*, f. 65.2° , $n_{70} 1.5842$. The analysis and values of n show that some di- NO_2 derivs. are present. The H_2O contained a small amt. of Cl or Br since it gave a ppt. with AgNO_3 . The nitration was carried out under slightly different conditions without a marked change in the result. Test expts. with (a) and (b), in which the compd. + 18 cc. of 0.35 N MeONa in MeOH were heated in sealed tubes at 85° for 5 hrs., showed that 98% of Cl in (a) and 98% of Br in (b) could be recovered as AgX , after pptg. the nitroanisoles by adding H_2O , filtering and washing free from alk. The slight error was found to be due to the formation of some NaNO_2 from (a) and (b) and since neither Cl nor Br are mobile in the chlorobromoanisole the halogen detn. was deficient to that extent. Known mixts. of the isomers (a) and (b), as well as the nitration product, were subjected to the same treatment. In one in which 74.3% (a) and 25.7% (b) were used 75.8% (a) were found. In another containing 83.9% (a) and 16.1% (b) 83.6% (a) were found. Analyses of the nitration product showed that 45.2% of (a) is formed: the remainder is (b). II. Nitration of $o\text{-ClC}_6\text{H}_4\text{Br}$. 10 g. of this compd. were added slowly to 5 g. HNO_3 (d. 1.50) at 0° , and the mixt. poured into H_2O . The solid product was distd. *in vacuo* as a white cryst. mass, m. $30\text{--}40^\circ$. Four products are possible in this case: (I) and (II) under the influence of Cl and (III)

and (IV) under the influence of Br. In (I) and (II) only Cl is mobile; in the others only Br is mobile. By treating with MeONa the ratio of the 1st group to the 2nd can be detd. The analysis was done as above and it was found that the mol. ratio for (I) + (II): (III) + (IV) is 1:0.80, so that the effect of Cl and Br on the velocity of substitution when both are present in the same ring is as 1:0.80. From these data it was also shown that all the nitration product was reacted upon by the MeONa. In the nitration of PhCl 30.1% of $o\text{-ClC}_6\text{H}_4\text{NO}_2$ were formed; with PhBr 38.3% $o\text{-BrC}_6\text{H}_4\text{NO}_2$ were formed. In nitrating $p\text{-ClC}_6\text{H}_4\text{Br}$ 54.8% (b) and 45.2% (a) were formed. Thus the ratio of the velocities of substitution caused by Cl and Br are $30.1:38.3x = 45.2:54.8$ where $x = 0.96$. III. Nitration of $p\text{-FC}_6\text{H}_4\text{Cl}$. The $p\text{-FC}_6\text{H}_4\text{Cl}$ was obtained from $p\text{-FC}_6\text{H}_4\text{NO}_2$ which in turn was obtained by diazotizing $p\text{-NO}_2\text{C}_6\text{H}_4\text{NH}_2$ or by nitrating PhF . The $p\text{-FC}_6\text{H}_4\text{NO}_2$ was reduced: 37 g. in 108 cc. 25% HCl + 208 g. Sn powder added slowly was finally warmed 2 hrs. on the H_2O bath. The $\text{FC}_6\text{H}_4\text{NH}_2$ (d) was sepd. by steam distn.

52 g. (d) diazotized by v. der L.'s method gave 34 g. $p\text{-FC}_6\text{H}_4\text{Cl}$, b. $130-1^\circ$, m. 27.7° , n_D^{20} 1.4990. 6 g. $p\text{-FC}_6\text{H}_4\text{Cl}$ added dropwise to 20 cc. HNO_3 (d. 1.50), decolorized with urea, at -3° to -5° was poured into H_2O after some hrs. and gave a yellow oil, which was partly dissolved in dil. NaOH , leaving 2 cc. of an insol. oil. The alk. soln. was acidified and extd. and gave $4,3,5\text{-Cl}(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{OH}$, m. 82° . Thus the F was eliminated in part in the nitration so that these expts. were abandoned. IV. Nitration of $p\text{-FC}_6\text{H}_4\text{Br}$. $p\text{-FC}_6\text{H}_4\text{NH}_2$ diazotized by v. der L.'s method gave $p\text{-FC}_6\text{H}_4\text{Br}$ (d) (yield, 68%), b. $151-2^\circ$, f. -17.4° , n_D^{20} 1.5310. Although the conditions of nitration were varied it was not possible to get a quant. nitration of (d). In every case part of the F was eliminated and $4,3,5\text{-Cl}(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{OH}$ was obtained. The best result was obtained as follows: 10 g. (d) were added dropwise to HNO_3 (14 cc. ordinary HNO_3 + 14 cc. (d. 1.50) decolorized with urea), cooled with EtOH + CO_2 snow, and kept at -5° to 0° . The mixt. was poured into H_2O , the oil sepd. and distd. *in vacuo*; the higher fractions crystd. The crystals were sepd. (m. 70°) and the oil washed with dil. alk. and distd. without decompn. The analysis of the oil corresponds to $\text{FBrC}_6\text{H}_2\text{NO}_2$. By treating with MeONa , as above, the oil was found to contain 30.5% of $4,2\text{-F}(\text{NO}_2)\text{C}_6\text{H}_3\text{Br}$. The presence of the 4,3-isomer was proved by the presence of NaF in the reaction products. V. Nitration of $o\text{-ClC}_6\text{H}_4\text{I}$. Körner (*Gass. chim. ital.* 4, 305 (1874)) studied the nitration of $p\text{-ClC}_6\text{H}_4\text{I}$ and in repeating his expts. H. got no better results. Considerable I was eliminated if it was introduced into concd. HNO_3 , and when it was dild. with glacial AcOH nitration did not occur. The product of nitration, $p\text{-ClC}_6\text{H}_4\text{NO}_2$, m. 83° , was easily obtained. The $o\text{-ClC}_6\text{H}_4\text{I}$ was obtained thus: 64 g. $o\text{-ClC}_6\text{H}_4\text{NH}_2$ in 1 l. H_2O + 200 cc. concd. H_2SO_4 were treated at a low temp. with 40 g. NaNO_2 in 200 cc. H_2O and the whole poured into 85 g. KI in 200 cc. H_2O , distd. with steam, washed with dil. alk., dried and distd. *in vacuo*. The sepn. of I in the nitration of the p -deriv. is explained as due to the fact that NO_2 prefers the p -position with respect to Cl and removes the I. Thus only 30% $o\text{-ClC}_6\text{H}_4\text{NO}_2$ are formed when PhCl is nitrated. Accordingly with $o\text{-ClC}_6\text{H}_4\text{I}$ less I should be eliminated by the HNO_3 ; this was found to be true. 5 g. $o\text{-ClC}_6\text{H}_4\text{I}$ was added slowly to 25 g. HNO_3 (d. 1.50) at -5° , poured into ice- H_2O and the ppt. washed with dil. alkali. The wash alkali was added to the acid filtrate and gave a violet color. The I was dissolved out with CS_2 and detd. with $\text{Na}_2\text{S}_2\text{O}_3$ to be 0.0673 g. The nitration products weighed 5.6 g. (calcd. 5.97 g.). The halogen content was a little too low so that it seemed probable that some $o\text{-ClC}_6\text{H}_4\text{NO}_2$ was formed by the elimination of I. Assuming this to be true H. calcd. the amt. that ought to be present from the free I detd. as 1.5%. Calcd. from the halogen detns., 4.47% should be present. Considering everything this is a good agreement. Taking the mean there ought to be 97% $\text{C}_6\text{H}_4\text{ClINO}_2$ and 3% $\text{ClC}_6\text{H}_4\text{NO}_2$. The nitration product was treated with MeONa for 22 hrs. at 85° as before. The solns. were dild. with H_2O , the org. compds. filtered off, the filtrate treated with AgNO_3 , etc. The AgCl + AgI was finally treated with Cl near the m. p. From the data it was detd. that the relative velocity of substitution caused by Cl and I in the same nucleus is 1:1.84. This result is again based on the suppositions (1) that MeONa reacts quant. on $\text{C}_6\text{H}_4\text{IClINO}_2$ and (2) that only the Cl or I in the p - or o -positions with respect to the NO_2 reacts. Special calculations showed that (1) is nearly quant. and that the error due to (2) must be very small if it exists. VI. Nitration of $o\text{-BrC}_6\text{H}_4\text{I}$. Having detd. the effect on the relative velocities of nitration of $\text{Cl}:\text{Br}$ as 1:0.80 and $\text{Cl}:\text{I}$ as 1:1.84 the ratio of $\text{Br}:\text{I}$ ought to be 0.80:1.84 if the Br and I act independently. Experience gives a different ratio so that it must be admitted that the 2 substituents act upon one another. $o\text{-BrC}_6\text{H}_4\text{I}$, prepd. like $o\text{-ClC}_6\text{H}_4\text{I}$ above, f. 5° . 5 g. $o\text{-ClC}_6\text{H}_4\text{I}$ were introduced into 25 cc. colorless HNO_3 (d. 1.51) at -10° . The product was treated as above. Free I equiv. to 0.1719 g. $o\text{-BrC}_6\text{H}_4\text{NO}_2$ was found. The nitration products weighed 5.4 g. (calcd. 5.79). The nitration product contained, therefore, 3.2% o -

$\text{BrC}_6\text{H}_4\text{NO}_2$, but from the halogen detn. it was calcd. to be 5.73% or an av. of 4.4%. As a result of the analyses of the product from the action of MeONa the relative velocity of substitution is $\text{Br:I} = 1:1.75$. *Theoretical considerations.* The relative velocities of substitutions caused by halogens in the same C_6H_5 ring are thus: $\text{Cl:Br} = 1:0.96$ (detd. by nitrating $p\text{-ClC}_6\text{H}_4\text{Br}$); $\text{Cl:Br} = 1:0.80$ (from $o\text{-ClC}_6\text{H}_4\text{Br}$); $\text{Cl:I} = 1:1.84$ (from $o\text{-ClC}_6\text{H}_4\text{I}$); $\text{Br:I} = 1:1.75$ (from $o\text{-BrC}_6\text{H}_4\text{I}$). So that as in the research of Wibaut the values for p -derivs. are not always identical with those for the o -derivs. Thus in the nitration of p -dihalogenbenzenes the NO_2 group cannot enter its favorite p -position because it is already occupied so that a certain amt. of perturbation would be expected. A comparison of the relative % of the isomers provided for by the 2 ratios shows that the perturbation is not large. With the o -derivs. some perturbation might be expected but it is hard to det. how much. With the p -I derivs. there is considerable elimination of I, but this is much less in the o -I derivs. From the ratios detd. that for Br:I should be 1:2.3 but only 1:1.75 was found. This error is significantly large but it is impossible to know how much, if not all, is due to the errors arising from the elimination of I (this was taken into account in the calcs. as nearly as possible) and in the detn. of the ratio of the 2 Ag halides. It has been shown by this work, together with that of Wibaut, that it is possible to calc. approx. the quantity of isomers which ought to be formed in the nitration of a compd. o - or p - $\text{C}_6\text{H}_4\text{XYZ}$ by knowing the quantities of isomers that are present in the products of the nitration of the compds. $\text{C}_6\text{H}_4\text{XY}$ and $\text{C}_6\text{H}_4\text{XZ}$. It will thus be possible to calc. in what proportion the nitrobromotoluenes will be present in the products of nitration of the bromotoluenes after having studied quant. the nitration of $p\text{-ClC}_6\text{H}_4\text{Me}$ and $p\text{-ClC}_6\text{H}_4\text{Br}$.

E. J. WITZEMANN.

The constitution of phenyl- o -nitroindone and its products of scission. M. BAKUNIN AND T. ANGRISANI. Univ. Naples. *Gazz. chim. ital.* 45, I, 197-204 (1915). —From the work done so far on the action of O_3 on the phenylnitroindones, which results in oxidation and hydrolysis, they are transformed into BzOH and 3-, 4- and 5-nitro-2-aldehydobenzoic acids, resp., and the formulas of the phenylnitroindones are 3-, 4- or 5- $\text{O}_2\text{N.C}_6\text{H}_4\text{CH:CPh.CO}$, resp. A comparison of the 3 formulas shows that

in the ring formation by the elimination of H_2O between the CO_2H group of BzOH and the Ph group of $\text{O}_2\text{NC}_6\text{H}_4\text{CH:CHCO}_2\text{H}$ the CO group always becomes o - with respect to the CH:CH group, whatever the position of the NO_2 may be. Of the 3 phenylnitroindones only the o -compd. gives a solid cryst. ozonide (a) which m. $100\text{--}50^\circ$, while the others are almost completely hydrolyzed during ozonization but the ozonides could be detected by their behavior. The position of the NO_2 or the greater solubility in CHCl_3 may have some influence on this result. (a) is sol. in C_6H_6 and is pptd. by petr. ether. H_2O , EtOH or NaOH soln. hydrolyzes it to give BzOH and 2,3- $\text{OHC-(O}_2\text{N)C}_6\text{H}_3\text{CO}_2\text{H}$. When (a) is boiled with Ba(OH)_2 a double compound of benzoic acid with m -nitrobenzoic acid (1:1 mol.) is pptd. on the addition of acid. This may be crystd. unchanged from H_2O , EtOH , C_6H_6 or AcOH , m. 139° . In H_2O it is dissociated. When the aq. soln. of the Ba salt is crystd. ($m\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2$) $_2\text{Ba}$ crystals out first. In C_6H_6 the double compd. is somewhat dissociated as shown by f. p. detns.; in AcOH and veratrole it is nearly completely dissociated. That this is a true chem. compd. and not a solid soln. is shown graphically by the melting curve of the system $\text{BzOH} + m\text{-O}_2\text{N.C}_6\text{H}_4\text{CO}_2\text{H}$. The curve shows 2 eutectics with the m. p. of the double compd. lying as a max. between them. The m. p. of BzOH is 120° . The first eutectic is at 109° with 88 mol. % BzOH . The other eutectic is at 120° with 20% mol. % BzOH . The $m\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ m. 141.5° . The double compd. with 50 mol. % of each m. 139° .

4,4'-Diphenylsemicarbazide as a reagent for the recognition of carbonyl derivatives. B. TOSCHI AND A. ANGIOLANI. Univ. Bologna. *Gazz. chim. ital.* 45, I, 205-13 (1915).—In a preceding paper (C. A. 8, 3018), the prepn. of $\text{Ph}_2\text{NCONHNH}_2$ (a) was described. As a result of further work it has been found to be an excellent reagent for the detection of C:O groups and is in many cases to be preferred to $\text{NH}_2\text{CONHNH}_2$, because it is quite stable as the free base, gives less sol. and more easily purified derivs. and reacts more quickly. The diphenylsemicarbazones of the aliphatic C:O derivs. are obtained most conveniently by treating the (a)-HCl in H_2O with an aq. or aq. EtOH soln. of the C:O compd. and the calcd. amt. of NaOAc. They are cryst., little sol. in H_2O , sol. in dil. acids, by which they are hydrolyzed with the formation of the original C:O deriv. The diphenylsemicarbazones of the sugars will be described in another paper. To obtain the diphenylsemicarbazones of the aromatic aldehydes it was best to treat the aldehyde with free (a) in EtOH. These are mostly difficultly sol. in cold EtOH and are pptd. in cryst. form. They are easily hydrolyzed by hot dil. acids. The aromatic ketones also react instantaneously with (a), while the reaction with $\text{NH}_2\text{CONHNH}_2$ is very slow. Several diphenylsemicarbazides of the terpene series and of hydroaromatic compds. were also studied. The action with carvone is peculiar and needs further investigation. Two g. of (a)-HCl + 0.5 g. acetone + excess NaOAc gave a white cryst. ppt. of acetone 4,4'-diphenylsemicarbazone, sol. in dil. HCl (warm HCl regenerates both components), m. 119° . In the same way were obtained the 4,4'-diphenylsemicarbazones of acetaldehyde, needles from Et_2O , m. $133-4^\circ$; *enanthole*, needles from dil. EtOH, m. $133-4^\circ$; *ethyl acetoacetate*, crystals from Et_2O , m. $103-4^\circ$; *glucose*, white needles with 1 H_2O , m. $164-6^\circ$, loses H_2O in *vacuo* gradually but not completely; *cinnamaldehyde*, yellow needles from MeOH, m. $164-6^\circ$; concd. H_2SO_4 gives an orange-red color; *cuminaldehyde*, crystals, m. 162° ; *salicylaldehyde*, needles from EtOH, m. 209° ; concd. H_2SO_4 gives a yellow color, *vanillin*, needles, m. $180-1^\circ$; concd. H_2SO_4 gives a yellow color; *piperonal*, yellow needles from EtOH, m. 173° ; concd. H_2SO_4 gives an orange-red color; *benzophenone*, needles, from EtOH, m. $186-7^\circ$; *citronellal*, crystals, m. $109-110^\circ$; *camphor*, needles from petr. ether, m. $154-5^\circ$.

E. J. WITZEMANN.

The action of bromine on carbon monoxide. A. PIVA. Ist. tech. Palermo. *Gazz. chim. ital.* 45, I, 219-37 (1915).—In a preceding paper with G. Levi (cf. C. A. 8, 2037) the compn. of gases formed by the decompn. of Na and Ca formates by heat was studied and the question whether or not CO reacts with Br in the analysis of the gases was considered. The literature, which is carefully reviewed, gives conflicting statements as to whether CO acting with Br in the sunlight gives COBr_2 or not. Careful expts. were made under a variety of conditions. The method used was as follows: approx. equal quantities of Br were sealed into small glass tubes which had been previously carefully cleaned and dried in a desiccator over CaCl_2 . The Br in each tube was weighed by weighing the tubes before filling and after sealing. They were then introduced into 100 cc. gas pipets of the proper form, the pipets were filled with carefully dried CO and the ends also sealed. The Br tube was broken inside by shaking roughly and the contents exposed to the kind of illumination selected for a definite interval. At the proper time the Br remaining unchanged was detd. as follows: One end of the pipet was broken off by striking it against the bottom of a suitable vessel containing 100 cc. of neutral 10% KI soln. The free I was finally titrated with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. It was found in 6 expts. in diffuse light exposed 10, 20, 40, 160, 240 and 320 hrs. that 1.75, 2.77, 3.55, 6.40, 8.92 and 10.56%, resp., of the Br was used up by the CO. Thus the quantity combined increases with the time but the velocity of reaction very quickly diminishes so that an equil. is reached. Another series of expts. was made to see if the light is indispensable. In the dark for 32 hrs. only 0.94% Br was used and since with

dry N_2 0.82% Br was apparently used the apparent effect is ascribed to impurities in the Br. In direct sunlight for 2, 4, 8 and 32 hrs., resp., CO absorbed 2.96, 6.90, 7.63 and 9.49% Br, showing that in the light equil. is approached much faster. In the 1st series the Br combined in the first 10 hrs. was 1.75%; in the 2nd for the 1st hr. it was 1.48%. The Br was especially and carefully purified and the CO now combined in the sunlight 1.89 and 2.29% Br in the 1st 8 and 32 hrs., resp., thus showing that the reaction is very much diminished by the removal of the impurity, which was thought to be mostly H_2O . The blank expt. with N_2 here showed an apparent loss of Br of only 0.018%. There are 2 possible interpretations of the disappearance of Br: (1) $CO + Br_2 \rightarrow COBr_2$ and $COBr_2 + H_2O \rightarrow CO_2 + 2HBr$; (2) $Br_2 + H_2O \rightarrow 2HBr + O$ and $CO + O \rightarrow CO_2$. Since it cannot be certain that the last traces of H_2O were removed it cannot be said that either process was excluded. The expts. were repeated using moist CO. In 80 and 160 hrs. 40.39 and 48.07% Br, resp., were combined in diffuse light. In direct sunlight 46.01% Br was combined in 32 hrs. With the idea that the HBr pressure interfered with the reaction some H_2O was placed in the tubes and the reaction repeated. In diffuse light in 10, 40, 60 and 160 hrs. 31.10, 58.20, 63.00 and 79.95% Br, resp., were combined. In the direct sunlight in 16 and 32 hrs. 70.48 and 78.7% Br, resp., were combined. In the dark 21.1% Br were combined in 32 hrs. Other expts. show even more clearly the quant. effect of the presence of H_2O . Since the velocity of reaction in the expts. made in conditions as nearly dry as possible was not quite zero it must still be admitted that $COBr_2$ may be formed as an intermediate product, even if only in small amts. Definite exclusion of this possibility could not be attained since very small traces of H_2O cannot be readily excluded. So that it is possible that $COBr_2$ is formed as an intermediate product in the oxidation of CO with Br and H_2O and is always formed only in the amts. capable of being decompd. by the H_2O present. The end products are in every case only HBr and CO_2 . E. J. W.

Ferric salts of organic acids (WEINLAND) 6. Reactions of sodium ethylate with methyl iodide and with substituted benzenes (ROBERTSON) 2.

II. BIOLOGICAL CHEMISTRY.

WILLIAM J. GIES, EDGAR G. MILLER, JR., PAUL E. HOWE.

FRANK P. UNDERHILL.

The influence of acids on the activity of dialyzed maltase. W. KOPACZEWSKI. *Ann. inst. Pasteur* 29, 157-64 (1915). See C. A. 8, 1791. GEO. T. CALDWELL.

The chemistry of rice-polishings. H. FRASER AND A. T. STANTON. Kuala Lumpur. *Lancet* 1915, I, 1021-22.—Fowls weighing about 1200 g. ordinarily consumed about 60 g. of unpolished rice daily. If fed on 60 g. of polished rice, they required in addition 5 g. of polishings for the maintenance of wt. and health. Polishings were extd. twice with 0.3% HCl. The polishings after extn. were tested and found valueless. Alc. was added to the ext. so as to bring the mixt. up to the strength of proof spirits. The ppt., which consisted of phytin, was rejected. The filtrate was nearly neutralized, concd. at a low temp. and its vol. so adjusted that 30 cc. of this soln. contained the material sol. in proof spirit from 5 g. of polishings. Fowls were fed on polished rice and once daily were given 30 c. of this soln. Their health was maintained. By making the proof spirit alk. to the extent of 0.5% with NaOH, a ppt. was obtained which in daily amts. representing 5 g. of polishings failed to maintain the health of the fowls. Likewise fowls which received this filtrate after neutralization and the removal of the alc. developed a polyneuritis. The inference from these expts. is that NaOH in weak soln. destroys the active substance. G. T. CALDWELL.

Enzymic adaptations. II. Lactase. R. BOMPIANI. Rome. *Arch. farm. sper.* 19, 423-38(1915).—The blood, the pancreatic and enteric secretions, and extracts of the pancreas, intestine and salivary glands of the adult dog contain no lactase. Although it was not possible to demonstrate lactase in the salivary glands after administration of lactose, the presence of this enzyme in the pancreas and the intestine was demonstrated beyond doubt after parenteral, intravenous or subcutaneous injection of lactose. A. W. DOX.

The membrane as the seat of chemical work. A. TSCHIRCH. Univ. Bern. *Arch. Pharm.* 252, 537-46(1914).—The conception that chem. work is due solely to plasma is held to be untenable. On the contrary, it appears certain that the membrane, especially that of intercellular nature or derivation, which must be colloidal in character, acts as the seat for very energetic work, both analytic and synthetic, either alone or through the help of enzymes. W. O. E.

Action of butyric acid in fertilization. A. BRACHET. *Compt. rend.* 159, 642-4 (1914).—B. claims that the fertilization membrane that is formed by the action of butyric acid in artificial fertilization is an accessory rather than an essential feature of the process. E. M. FRANKEL.

The influence of balanced and non-balanced salt solutions upon the osmotic pressure of the body liquids of Fundulus. JACQUES LOEB and HARDOLPH WASTENEYS. Rockefeller Inst. *J. Biol. Chem.* 21, 223-38(1915); cf. *C. A.* 7, 617, 1887.—The depression of the f. p. of the body juices of *Fundulus* was detd. after keeping the fish in sea water (and other balanced solns.) and in non-balanced solns. of different concns. In 0.5 *M* sea water, the osmotic pressure of the body juices diminished to a certain limit. This decline can be inhibited by feeding. Balanced solns. in excessive concn. increase the osmotic pressure of the body juices. In non-balanced solns. this change is much more marked. It is less with hypertonic solns. of NaCl than with solns. of the same concn. of Na₂SO₄, NaBr, etc. This is probably due to the fact that in the latter case the fish die as a result of the toxic action of the salt before a marked increase in the osmotic pressure of the body juices can occur. The expts. are regarded as supporting the view that non-balanced solns. increase the permeability of the cell.

I. GREENWALD.

The relation of the quality of proteins to milk production. E. B. HART and G. C. HUMPHREY. Univ. Wisc. *J. Biol. Chem.* 21, 239-53(1915).—Expts. on cows, with diets containing 9-10% protein, of which 7% was digestible, showed that milk proteins were more efficient in securing a positive N balance and continued milk flow than were corn or wheat proteins. When the latter were fed, there was a negative N balance but no decrease, at least for some time, in the amt. of milk protein or of milk solids produced. The loss of flesh was quite evident. The importance to the dairyman of the relative efficiency of different proteins in milk production is emphasized. I. GREENWALD.

Studies on the reductase of liver and kidney. III. The influence of heat, light and radium emanations on the activity of reductase. DAVID F. HARRIS and HENRY J. M. CREIGHTON. *J. Biol. Chem.* 21, 303-8(1915); cf. *C. A.* 9, 1489.—The reductase of cat liver is inhibited by heat, temp. as low as 30° producing a perceptible diminution in activity. The degree of inhibition increases slowly with the temp. to about 65°, then very rapidly. At 72°, heating for 3 min. completely inactivates the enzyme. Light and Ra Em have no appreciable effect on the activity of reductase.

I. GREENWALD.

Tissue fibrinolysins. MOYER S. FLEISHER and LEO LOEB. Barnard Hosp., St. Louis. *J. Biol. Chem.* 21, 477-501(1915).—Tissues have the power to dissolve coagulated plasma. This may be coagulated about the piece of tissue or may be coagu-

lated first and the tissues then placed upon it. The action is assumed to be due to the presence of fibrinolysins. "Certain organ systems, especially the genito-urinary and nervous systems, contain fibrinolysins. Heating organs to 56° for 30 min. renders them inactive. Various species of animals differ in the fibrinolytic power of their organs; there also exist great variations in the solubility of different kinds of blood. The liver counteracts the effect of the fibrinolysins. The substances found in certain organs, which inhibit the coagulation of the blood, are perhaps identical with the fibrinolysins. The fibrinolysins have a considerable biological significance in preventing growth processes; they are antagonistic to the tissue coagulins which promote growth processes. The fibrinolysins do not seem to be identical with those splitting ferments which produce autolysis."

I. GREENWALD.

Relative efficiency of various parts of the spectrum for the heliotropic reactions of animals and plants. J. LOEB AND H. WASTENEYS. *J. Exp. Zoölogy* 19, 23-35(1915).—The most efficient region in the spectrum for the production of heliotropic curvatures in the hydroid *Eudendrium* is situated in the blue at 4735 Å.u. This region coincides approx. with the one found by Blaeuw for the seedlings of oats, namely 478 Å.u. (cf. *Rec. travaux botaniques Néerlandais* 5, 209(1909)). The regions in the red, orange and yellow are practically without effect in both *Eudendrium* and *Avena*. B. H.

Problems of biochemistry in the next twenty-five years. F. QUADE. *Z. angew. Chem.* 28, I, 265-8(1915).—A general statement of the present state of progress of biochemistry and suggestions for future development. E. H.

Osmotic equilibrium between blood and milk. F. H. VAN DER LAAN. Utrecht. *Chem. Weekblad* 12, 522-41(1915).—Freezing-point detns. were made on milk and on defibrinated blood, to det. whether or not osmotic equil. exists between them. With the same cow, the mean of 26 f.-p. lowerings for the blood and for the milk were identical (0.546°). The mean f.-p. depression detd. by the author for blood from 21 cows was 0.522°; all the f.-p. detns. found in the literature lead to a general mean of 0.55°, the values ranging from 0.53 to 0.57°. Increase or decrease in food supply is without effect on the f.-p. depression of the blood. Strong artificial diln. or concn. of the contents of the alimentary canal may influence the f. p., but both blood and milk are affected the same. Udder diseases which do not affect the general health of the animal do not affect the f.-p. depression of the milk; that of milk from a diseased teat is the same as that from a sound teat on the same cow. Increases occasionally observed are due to bacterial infection.

GEORGE W. MOREY.

Experimental study of lipolytic action. K. G. FALK. *Proc. Nat. Acad.* 1, 136-142(1915).—A review of the author's work (cf. *C. A.* 6, 2625; 7, 2230, 2580; 8, 1435, 2733; 9, 634, 1922) on the influence of various conditions upon the activity of esterases and lipases. The hydrolytic action of lipase owes its specific character to 2 effects: (1) The pptn. or coagulation of the enzyme by the substrate; (2) the effect of the enzyme on substrate, which is due to the presence in the former of special groupings. These groupings may be similar to those contained in simpler nitrogenous substances, such as amino acids, which also bring about hydrolysis of esters. W. A. PERLZWEIG.

Relation of mitochondria to granules of the vital azo-dyes. KATHERINE J. SCOTT. Johns Hopkins Med. Sch. *Science* 41, 834-5(1915).—A cytological study of those cells in the subcutaneous tissue of mice that react to azo dyes revealed no cases of identity between granules produced by azo dyes and mitochondria. W. A. P.

Catalase reaction of milk (TAYLOR) 12. Determination of chlorine in vegetable matter (DE JONG) 7.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

The use of the naphthaline-sulfochloride method for detecting the partial hy-

drolysis of flesh albumin. WALTHER LOB. *Chem. Ztg.* 39, 369-70(1915).—L. gives results confirming those of Bergell and Fischer (*C. A.* 8, 2404). The following improved method has been devised: The albumin is removed from the soln. from fresh meat, or ext., prepared exactly according to B.'s method, by boiling with salt and AcOH, the filtrate neutralized and treated in the usual way with naphthaline-sulfochloride and the alk. aq. layer filtered and acidified. The viscous and finely divided ppt. is allowed to stand long in the cold, the supernatant liquid poured through a filter, the ppt. washed well by decanting with cold H₂O, then dissolved in a little hot dil. NaOH soln. which is poured through the filter into a graduated flask, washed and the N found in an aliquot part by Kjeldahl's method. J. H. MOORE.

Simple and accurate method for the estimation of chlorides in albuminous liquids. C. GAZZETTI. *Arch. fisiol.* 11, 81-8(1914).—A small, measured quantity of the liquid is dild. with H₂O in a 100 cc. flask, 3 cc. of 50% ferric alum soln. are added, the pptd. ferric albuminate is dissolved by the addition of conc. HNO₃ drop by drop, and a measured excess of 0.02 N AgNO₃ soln. is added to the clear soln.; the colloidal matter in the soln. prevents the pptn. of AgCl. The mixt. is dild. with H₂O to about 97 cc., and is then made up to the mark by the addition of conc. HNO₃. This causes the flocculation of the albumin and the pptn. of AgCl. The whole is filtered, and in 50 cc. of the clear filtrate the excess of AgNO₃ is estd. by titration with 0.02 N KCNS soln.

H. S. PAINE.

Detection of albumin in urine. ZOICHER. *Boll. chim. farm.* 52, 504(1913).—Z. recommends the substitution of a 20% citric acid soln. for the 20% AcOH soln. in the detection of albumin in urine; citric acid tablets of 0.5-1.0 g. may be used to advantage. The use of citric acid together with K₄Fe(CN)₆ is believed to afford an accurate test for albumin in urine.

H. S. PAINE.

Modification of the Heller ring test for the detection of albumin in urine. MICHEL. *Boll. chim. farm.* 52, 718(1913).—M. recommends the substitution of HNO₃ of sp. gr. 1.4 satd. with NH₄NO₃ for the HNO₃ usually employed in the Heller test. The use of the new reagent facilitates the production of a distinct zone of contact between the HNO₃ and urine, thus rendering the ring more readily perceptible in case albumin is present. When the 2 layers of liquid are mixed a distinct turbidity is produced; the latter disappears with the production of a light yellow coloration when the mixt. is heated and reappears on cooling if a considerable amt. of albumin is present. When ordinary HNO₃ is employed as a reagent the turbidity is dissipated on mixing the 2 layers and does not reappear.

H. S. PAINE.

Detection of albumin in urine. R. C. HOLT. *Boll. chim. farm.* 52, 719(1913).—In the Heller test a dense, dirty white ring (sometimes merely a cloudy appearance), which differs from the ring formed at the point of contact with albumin, is formed above the zone of contact of the urine and HNO₃. This reaction is obtained only in cases of pneumonia and then only in fresh urine; it is not produced in 24 hr. urine.

H. S. PAINE.

Diascopy of traces of blood. ANGELO DE DOMINICIS. *Boll. chim. farm.* 53, 162-3(1914).—In the case of dried blood adhering to certain objects it is sufficient to remove a tiny particle and carefully crush it in a trace of oil of origanum upon a glass slide with the rounded end of a small glass rod. A small drop of a satd. soln. of eosin in paraldehyde is then added and the prep. is ready for observation; artificial light (with proper manipulation of the diaphragm) is employed. The prep. may be preserved with a drop of euparal. If the blood has been absorbed by some substrate material, a portion of the latter (including both blood and substrate) is rasped with a scalpel to a fine powder and treated as above. A more lightly tinted paraldehyde soln. of eosin may be employed and the object under exam. may be crushed directly in the

paraldehyde soln. of eosin if desired. The stained corpuscles may be readily detected (either isolated or in groups). This procedure is superior to other methods of investigating blood traces in that it may be applied to very minute particles of blood. This method is especially advantageous in examining traces of blood upon rusty Fe; the blood pigment is soon destroyed under these conditions and the stroma becomes colorless, so that diascopy is the only means of detecting such blood traces. H. S. P.

Determination of quinine in the urine. M. NISCHL. *Boll. chim. farm.* 53, 737 (1914).—Quinine in the urine may be detd. quant. as the citrate. The latter may be obtained by satg. the quinine (extd. with Et_2O) with citric acid dissolved in Et_2O . The urine is rendered strongly alk. before shaking with Et_2O . Detn. by this method showed that 34.35% of the quinine introduced into the organism was excreted in the urine after 72 hrs. (25% in the first 24 hrs.). Fe and As ingested with the quinine had no influence either on the absorption or the elimination of the quinine.

H. S. P.

A simple colorimeter for use in the phenolsulfonephthalein test for kidney function. J. S. BROTHERHOOD. Grand Rapids. *J. Am. Med. Assoc.* 64, 1757(1915).—This consists of a rack to hold 14 test-tubes containing the standard solns. and a sliding shield to hold the tube whose content is to be measured.

L. W. RIGGS.

Thorium—a new agent for pyelography. J. E. BURNS. Baltimore. *J. Am. Med. Assoc.* 64, 2126-7(1915).—Solns. of $\text{Th}(\text{NO}_3)_4$ cannot be used on account of their irritating action and the pptn. of insol. salts in the urine; also when intravenously administered, intravascular clotting is produced. The neutral soln. of $\text{Th}(\text{NO}_3)_4$ and $\text{Na}_2\text{C}_2\text{H}_3\text{O}_7$ possesses the necessary opacity to Röntgen rays, and apparently all other desirable qualities. To make 100 cc. of a 10% soln. 10 g. of $\text{Th}(\text{NO}_3)_4 \cdot 6\text{H}_2\text{O}$ are dissolved in as little H_2O as possible; to this soln., kept hot on a water bath, 30 cc. of a 50% soln. of $\text{Na}_2\text{C}_2\text{H}_3\text{O}_7$ are added in small amts. with stirring. A white ppt. is formed after the first addition of the citrate; this dissolves on further addition. This mixt. is then made neutral with N NaOH and H_2O added to 100 cc. On filtering a clear limpid soln. is obtained; its stability is not affected by boiling. "This soln. can be injected intravenously up to 1.5 cc. per kg. of body wt., and given by the stomach up to 4 cc. per kg. of body wt. in dogs without causing any change in the phenolsulfonephthalein output, blood urea content, hemoglobin content, or cellular elements of the blood."

L. W. RIGGS.

Retention stomach-tube for continuous study of stomach functioning. L. R. LANZA. *Riforma medica* 31, No. 21(1915); *J. Am. Med. Assoc.* 65, 208.—A very fine tube is used and is not introduced until after the meal in order to avoid stimulating the stomach to extra secretion or peristalsis. The tube is then retained, and the stomach contents examd. every 10 or 15 min. for a period of 2 hrs.

L. W. RIGGS.

Microchemical color reaction in the blood corpuscles. C. RUBINO. *Riforma medica* 31, No. 20(1915); *J. Am. Med. Assoc.* 65, 207-8.—The reagent is a filtered 10% alc. soln. of benzidine to which is added just before using 1 drop of H_2O_2 for each 25 drops of the benzidine soln. Freshly drawn blood is allowed to evap. and the reagent, prepd. as above, is added to the residue and left in contact for 3 min. The reagent is then washed off first in alc., then in running water and the specimen mounted in neutral balsam. The figured elements of the blood, when thus treated, assume different colors, none like that of the benzidine soln. itself.

L. W. RIGGS.

Goeldner's test for cocaine. LEON A. RYAN. *J. Am. Chem. Soc.* 37, 1960-1 (1915).—A repetition of G.'s test (*Pharm. Z. Russland* 28, 489; *Z. anal. Chem.* 40, 820(1901)) with chem. pure materials gave no response. Pure resorcinol and concd. H_2SO_4 give a faint yellowish color but cocaine-HCl does not bring out the "beautiful

corn flower-blue color." H_2SO_4 containing minute traces of nitrates or nitrites, however, does produce such a color with resorcinol alone. An amt. of KNO_3 equiv. to 0.000001 g. of N is sufficient to give the color. CHAS. A. ROULLIER.

The possibility of titrating the monosubstituted amino group of amino acids with formol. ANTONINO CLEMENTI. Univ. Rome. *Atti accad. Lincei* 24, I, 352-9(1915).—The Sørensen formol titration method (*Z. physiol. Chem.* 60, 2; 64, 120), which is based on Schiff's expts. and which permits of the titrimetric detn. of the quantity of amino groups in amino acids, has not as yet been applied to amino acids in which the amino group is partly or completely substituted. C. made expts. of this kind with sarcosine (methylglycine), $\text{MeNHCH}_2\text{CO}_2\text{H}$. It was shown that the amino group even if monosubstituted in this way, reacts with HCHO . It was found that sarcosine reacts with HCHO to give methylenedisarcosine, $\text{CH}_2(\text{NMeCH}_2\text{CO}_2\text{H})_2$, and reacts in the Sørensen formol titration like a monobasic acid. Sarcosine conducts itself in the titration just like glycine, except that the values are a little lower, so that in titrating monosubstituted amino acids according to Sørensen's method it is necessary to titrate to the intense red coloration of the phenolphthalein. E. J. WITZEMANN.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The action of the rare earths on bacteria. A. SIMONINI. Wien. *Centr. Bakt. Parasitenk.*, I Abt. 76, 398-407(1915).—The cultural and morphological characteristics of bacteria are changed when they are treated with Th salts and grown again in bouillon. Cf. C. A. 8, 3315. JULIAN H. LEWIS.

The lipoids of blastomyces. A. AMATO. Univ. Palermo. *Centr. Bakt. Parasitenk.*, II Abt. 42, 689-98(1915).—Lipoids were demonstrated microchemically and chemically in *Saccharomyces ellipsoideus*. JULIAN H. LEWIS.

Bacterial action on tryptophan and indole. E. HERZFELD AND R. KLINGER. Univ. Zürich. *Centr. Bakt. Parasitenk.*, I Abt. 76, 1-12(1915).—Not only can indole-producing bacteria (*B. coli* and *Vibrio cholerae*) decompose tryptophan, but also those that do not produce indole (*B. typhosus* and others). The consumption of tryptophan is decreased markedly if other protein cleavage products are supplied, as is the case with peptone culture media. Many bacteria produce more tryptophan through peptolysis than they can destroy; others have such a small peptolytic action that the tryptophan is all decomposed as quickly as it is formed. Several bacteria can destroy free indole but cannot form indole. JULIAN H. LEWIS.

The *Streptococcus mucosus*. Its capsule and its pathogenic properties. W. L. HOLMAN. Univ. Pittsburg. *J. Path. Bact.* 19, 478-85(1915).—*Streptococcus mucosus* grown in lactose serum develops a capsule that is plainly visible in moist unstained preps. The capsule is probably made visible by the action of its own acids of fermentation on the albuminous material in the capsular substance. The resistance of this capsule to the solvent power of water, alc., ether, dil. acids and other substances is very high. It is rapidly dissolved by *N* NaOH and by glacial AcOH. A glucoprotein was not demonstrated in the capsules. Considerable discussion of the pathogenicity of the organism is given. JOHN T. MYERS.

Use of ethyl chloride in the sterilization of bacterial cultures and the preparation of bacterial vaccines. ALBERT BERTHELOT. Pasteur Inst. *Compt. rend. soc. biol.* 76, 29-30(1914).—B. claims priority, as against L. Camus, for the application of Et chloride in the sterilization of bacterial cultures and the purification of vaccines. The following technic is recommended: Reduce the temp. of the bacterial culture or vaccine to 0° by placing the container in ice and introduce 1-2 cc. of liquid Et chloride for each 10 cc. of emulsion, using a capillary jet. Shake the mixt. gently, place the container in a Dewar tube and allow to stand 24-48 hrs. The Et chloride may then be rapidly

expelled by placing the container in a bath of warm H_2O . In the case of certain bacteria sterilization by means of Et chloride is slower than that produced by Et_4O . Some bacteria which are very resistant to heat must be in contact with Et chloride for more than 48 hrs. in order that sterilization may be effected, while other species merely suffer a diminution in vitality after a period of 24 hrs. contact. It is, therefore, necessary, before expelling the Et chloride, to ascertain definitely that sterilization has been effected. Et chloride is preferable to Et_4O in that the former is less volatile, less sol. in H_2O and does not contain transformation products.

H. S. PAINE.

Identification of the pathogenic members of the typhoid-colon group of bacilli. J. H. SMITH. *Brit. Med. J.* 1915, II, 1-5.—The method is based on the literature and the experience of the Lister Inst. One full and 3 abbreviated methods are described. Two tables show fermentations and other properties. A. H. RAHE.

Ger., 282,755, Feb. 4, 1914. E. BEINTKER. A stain for bacteria is prepared in solid form, and for use need only be dissolved in H_2O . These preps. are made by substituting sugar or the like for the alc. heretofore used. E. g., to obtain carbol fuchsin in solid form, for use as a stain for the tubercle bacillus, 1.0 part fuchsin, 5.0 of crystd. carbolic acid, 15.0 of lactose or pulverized sugar, are rubbed together. The resulting powder is made up into tablets. To obtain the soln., 2 g. of the powder are boiled with 10 cc. H_2O in a test tube.

Ger., 283,072, Feb. 11, 1914. K. HERTHA. Closure for side and bottom openings in glass vessels for growing bacteria and other organisms.

Ger., 283,112, Aug. 20, 1913. Addition to 229,970 (C. A. 5, 2698). F. BRAMIGK. Prepn. in powder form of dehydrated culture media for bacteria. In order to prevent increase of temp. above the necessary 37° , in the process of the principal patent, and yet to secure a rapid dehydration, the desiccation is effected *in vacuo*, whereby the period of drying is materially shortened and the danger of bacterial growth is at the same time lessened. In order to entirely remove this danger, the medium is sterilized with steam before subjecting to vacuum. The drying *in vacuo* can be favored by drawing preheated, filtered or sterilized air over the medium. The constituents of the medium may be separately prepared and dried and then mixed. This is especially desirable when one constituent (agar) can only be dehydrated after a very long treatment; so long a period of drying is not desirable for other constituents (albumin mols.).

D. BOTANY.

CARL L. ALSBERG.

The nuclein bases found in the shoots of *Aralia cordata*. K. MIYAKE. Tohoku Imp. Univ., Japan. *J. Biol. Chem.* 21, 507-9(1915).—An attempt to separate the nuclein bases of *Aralia cordata* was made. The presence of guanine and xanthine was proved. Adenine and hypoxanthine were not detected. I. GREENWALD.

Nature of the sugars found in the tubers of sweet potatoes. K. MIYAKE. Tohoku Imp. Univ., Japan. *J. Biol. Chem.* 21, 503-6(1915).—Sweet potatoes contain glucose, fructose and sucrose, but not pentose, galactose, mannose or maltose. I. G.

Inheritance of color in melandrium. GEORGE HARRISON SHULL. *Ber. deut. botan. Ges.* 31, 40-80(1913).—The presence of the inheritance factor *L*, which Bauer considers most necessary for the synthesis of chlorophyll, is corroborated. Without this factor the plant is entirely chlorophyll-free, and dies of starvation. Three various, non-Mendelian cases of bright-colored leaves are described, and their color inheritance discussed.

B. HOROWITZ.

Effects of illuminating gas on root systems. E. M. HARVEY AND R. C. ROSE. *Botan. Gas.* 60, 27-44(1915).—When illuminating gas is passed through soil the odorous constituents of the gas are readily absorbed by the soil particles and strongly held.

These odorous substances are very slightly, if at all, toxic to roots of plants growing in a soil containing them. The constituents of illuminating gas that remain in a gaseous state in the soil interstices are the chief cause of injury to root systems. Among these constituents ethylene is probably the most harmful, except in extremely high concns. of illuminating gas, where the toxicity of other substances, together with other factors, would be expected to play a part. With illuminating gas abnormalities appear in certain tree seedlings within 8-21 days, with concn. 1 part illum. gas to 4 parts air (air of the soil), or as low as 1 part of illum. gas to 40 of air. Ethylene alone, when used in concns. corresponding with those found in illum. gas, gives abnormalities similar in type and degree. High concn. of illum. gas results in the rapid killing of the roots. If illum. gas is allowed to flow very slowly through a soil in which woody plants are growing, abnormal tissue development in the root will very often ensue. In low concn. of illum. gas hydrolysis of starch and some other related chem. reactions are accelerated. By the use of etiolated sweet-pea seedlings, small amts. of illum. gas in the soil could be detected where the odor of gas was indistinguishable by the usual methods.

B. HOROWITZ.

Oxidation in healthy and diseased apple bark. DEAN H. ROSE. *Botan. Gaz.* 60, 55-65(1915).—Ext. of apple tree bark affected with Illinois canker causes greater and more rapid oxidation of pyrogallol than does the ext. of healthy bark. Diseased bark ext. is less acid than healthy bark ext., from which R. concludes that oxidation is in approx. inverse ratio to the acidity of the ext. in the range of concns. used. B. H.

A three-salt nutrient solution for plants. J. W. SHIVE. *Am. J. Botany* 2, 157-60 (1915).—S. found that the soln. giving best growth of wheat tops contained the 3 salts in the following volume-molecular partial concn.: KH_2PO_4 0.0180 *M*, $\text{Ca}(\text{NO}_3)_2$ 0.0052 *M*, MgSO_4 0.0150 *M*. This soln. produced better growth than Knop's soln. of the same total osmotic concn., and Tottingham's 4-salt soln. composed of KNO_3 , KH_2PO_4 , $\text{Ca}(\text{NO}_3)_2$ and MgSO_4 .

J. J. SKINNER.

The exchange of ions between the roots of *Lupinus albus* and culture solutions containing one nutrient salt. R. H. TRUE AND H. H. BARTLETT. *Am. J. Botany* 2, 255-78(1915).—Roots of *Lupinus albus* grown in darkness in distd. H_2O gave up their salts to the H_2O at a varying rate until the death of the plants through exhaustion of the reserves. KH_2PO_4 and KCl solns. act essentially like distd. H_2O in the concn. studied. Solns. of K_2SO_4 and KNO_3 show a slight absorption phase resulting in a minimal net gain in salts to the plant but otherwise differ little from the P and Cl. Absorption and growth take place in NaCl essentially as in KNO_3 and K_2SO_4 . Solns. of $\text{Mg}(\text{NO}_3)_2$ and MgSO_4 support a slight but clearly developed absorption phase resulting in a net gain in salts to the plant. A net leakage of salts is seen in the more dil. solns. and the toxic action in those of greater concn. $\text{Ca}(\text{NO}_3)_2$ and CaSO_4 in all concns. studied are actively absorbed by the roots and apparently enable the plants to retain possession of the salts already present.

J. J. SKINNER.

Biochemical investigation of the "Rübenschwanzfäule" of the sugar beet. J. BODNAR. Budapest. *Biochem. Z.* 69, 245-56(1915).—The first of the following figures is for the sound beet, the second for the diseased: H_2O -content, 73.8-78.9, 71.1-74.8; acidity, 14.2-20.2 cc. 0.1 *N* KOH, 24.8-63.1 cc.; cane sugar, 15.2-17.1, 6.9-14.8; invert sugar, 0.00-0.10, 0.35-1.62; ash, 3.92-5.16, 6.26-8.08; Al in ash, 1.42-2.57, 6.86-10.21.

C. J. WEST.

The diminution of electrolytes in germinating seeds. S. DEZANI AND T. BAROCELLI. Univ. Turin. *Atti accad. sci. Torino* 50, 169-80(1914).—In earlier expts. (C. A. 8, 3454) it was found that the elec. cond. of distd. water in which seeds were germinating gradually increased. These observations were followed out accurately

with *Zea mais* and it was found that in 48 hrs. 3.26% of the total inorganic matter, on the average, was transferred to the water.

E. J. WITZEMANN.

F. PHYSIOLOGY.

ANDREW HUNTER.

Composition and physiological activity of the pituitary body. FREDERIC FENGER. Chicago. *J. Biol. Chem.* 21, 283-8(1915).—"The posterior lobe of the pituitary body of the hog is twice as large in proportion to the wt. of the entire gland as in cattle. The physiol. activity of the posterior lobe, when detd. according to the isolated uterus method, is practically the same for cattle as for hogs. No distinct variation in activity and chem. comp. of the posterior lobe of the pituitary exists in cattle. Approx. 10% of beef glands contain colloid masses secreted between the anterior and posterior lobes. This material is insol. in acidulated H_2O and does not possess any pronounced uterine contracting power.

I. GREENWALD.

The synthesis of hippuric acid in nephrectomized dogs. F. B. KINGSBURY AND E. T. BELL. Univ. Minn. *J. Biol. Chem.* 21, 297-301(1915).—Using the methods described by Kingsbury (*C. A.* 9, 2259), hippuric acid was found in the blood and tissues of nephrectomized dogs, after administration of Na benzoate and glycine, thus proving that the kidney is not the only organ capable of synthesizing hippuric acid. I. G.

Vividiffusion experiments on the ammonia of the circulating blood. ALICE ROHDE. Johns Hopkins Univ. *J. Biol. Chem.* 21, 325-30(1915); *Proc. Nat. Acad.* 1, 357 (1915).—Confirming the observations of Medvedev (*C. A.* 5, 3292) it was found that in aseptically drawn blood there is a liberation of NH_3 on standing. In a dialysate obtained from circulating blood by the vividiffusion method (*C. A.* 8, 725, 3314) there is no liberation of NH_3 on standing. If the dialysis is continued until equil. between blood and dialysate is attained, the NH_3 content is the same.

I. GREENWALD.

Significance of certain internal conditions of the organism in organic evolution. F. H. PIKE AND E. L. SCOTT. *Am. Naturalist* 49, 321-59(1915).—The regulatory mechanisms are interpreted in terms of chem. equil.

B. HOROWITZ.

The cholesterol content of individual organs and the blood in hunger. V. Physiology of cholesterol metabolism. M. A. ROTHSCHILD. Univ. Freiburg. *Beitr. path. Anat.* 60, 227-31(1915).—In animals starved 2-9 days there was found an increase of cholesterol in the blood, bile, adrenals, and liver. The gall bladder epithelium and bile capillaries were free of anisotropic droplets. The increase of cholesterol in starvation indicates that it is the result of catabolism.

JULIAN H. LEWIS.

The relation of the spleen to cholesterol metabolism. VI. Physiology of cholesterol metabolism. W. B. SOPER. Univ. Freiburg. *Beitr. path. Anat.* 60, 232-44(1915).—If the lymphatic tissue of the rabbit is destroyed by mesothorium emanations, there is no change in the cholesterol content of the blood and the reticulo-endothelium is not injured. After extirpation of the spleen a gradual and marked increase in the cholesterol of the blood follows. The results can only be due to the removal of the reticulo-endothelium. The relation of the spleen to cholesterol metabolism, then, can be concerned only with this part of the organ. In hypercholesterolemia there is an increase of cholesterol in the spleen, especially in the reticulo-endothelium.

JULIAN H. LEWIS.

Nature of the nerve impulse. SHIRO TASHIRO. *Proc. Nat. Acad.* 1, 110-4(1915).—On the basis of his expts. on the correlation of the degree of irritability, of the direction and rate of the nerve impulse on one hand, and the production of CO_2 on the other, T. maintains that 2 chem. conditions are necessary for the conduction of the nerve impulse: (1) Excitability due to the presence of a chemically unstable substance of unknown constitution; (2) increase in chem. change at the place of stimulation must

be sufficiently greater than in its vicinity, the impulse then going in that direction, or there must be present a gradient of chem. activity. The nerve impulse is believed to be a propagation of chem. change, due to restoration of a metabolic equil. disturbed at the point of stimulation. This propagation proceeds toward the point of lesser chem. activity, as measured by the CO_2 output. W. A. PERLZWEIG.

The oxidizing power of oxyhemoglobin and erythrocytes. J. F. McCLENDON. Univ. Minn. *J. Biol. Chem.* 21, 276-81(1915).—Dog oxyhemoglobin and methemoglobin and goose hemoglobin rapidly oxidize α -naphthol, aloin, *p*-phenylenediamine and Vernon's substrate (α -naphthol and *p*-phenylenediamine) but not benzidine and guaiacol. H_2O_2 is not necessary. Laked erythrocytes oxidize Vernon's substrate more rapidly than do the same concns. of intact cells. This is probably due to the fact that in the latter case the hemoglobin is in the cells and cannot act until the substrate has reached it by diffusion. The use of induction shocks to increase the permeability led to inconclusive results. Cf. C. A. 9, 1920. I. GREENWALD.

Physiological climatology. II. W. A. OSBORNE. *J. Physiol.* 49, 133-8(1915).— H_2O evapd. from the skin of man was compared with that lost simultaneously from a moist sphere subjected to the same climatic conditions. Air temp. is the leading factor in causing skin evapn., but the relationship is not of the simple linear type. At high temps. H_2O is lost relatively more rapidly by the skin because of difference in temp. between the body surface and the evaporimeter, the latter being that of the wet bulb thermometer, the former more nearly that of the atm. J. F. LYMAN.

Influence of tonsil extract on the blood picture. C. B. FARMACHIDIS AND A. VATTUONE. *Policlinico* 22, No. 3(1915); *J. Am. Med. Assoc.* 64, 1537.—Both white and red corpuscles were increased in number under the influence of treatment with tonsil ext. Previous research described points to a glucolytic action by the ext.; also that this ext. is able to arrest the fatal toxic action of epinephrine. L. W. RIGGS.

Ventilation (WINSLOW) 14.

G. PATHOLOGY.

H. GIDEON WELLS.

The diagnostic value of uric acid determinations in blood. OTTO FOLIN AND W. DENIS. *Arch. Intern. Med.* 16, 33-7(1915).—"In gout the blood is invariably high in uric acid (U. A.), while the other waste-products represented in the non-protein N (N. P. N.) of the blood are usually within the normal limits. In arthritis also, the blood is not infrequently abnormally high in U. A., but such cases usually have abnormally high N. P. N. as well. Neither qual. tests for U. A. in the blood nor quant. detn. of the U. A. alone can be depended on in the differential diagnosis of gout and other joint diseases." For this purpose the patient must be put on a purine-free diet and the U. A. detns. accompanied by detns. of the N. P. N. (or urea). I. GREENWALD.

The relation of calcium to the delayed coagulation of the blood in obstructive jaundice. ROGER I. LEE AND BETH VINCENT. *Arch. Intern. Med.* 16, 59-66(1915).—Blood from a case of obstructive jaundice showed a very slow coagulation time. The addition of CaCl_2 shortened this to within normal limits. The administration of Ca lactate to the patient led to a shortening of the coagulation time after a few days. The addition of a small amt. of bile to normal blood delayed clotting. This delay could be obviated, if not too much bile were used, by the addition of CaCl_2 . In a dog, in which an exptl. obstructive jaundice was produced by ligation and resection of the common bile duct, there was a marked lengthening of the coagulation time, which could be shortened by the addition of CaCl_2 . It is suggested that the bile delays clotting by combining the Ca of the blood in such a manner as to make it unavailable for the clotting process. I. GREENWALD.

Complement fixation in pertussis. MIRIAM OLMSTAD AND PAUL LUTTINGER. N. Y. Board of Health. *Arch. Intern. Med.* 16, 67-85(1915).—"Complement fixation tests on sera from 111 cases of pertussis or suspected pertussis support the theory that the Bordet-Gengou bacillus is the etiological factor in the disease. The complement-fixation test may be of value in the diagnosis of doubtful cases of pertussis."

I. GREENWALD.

A study of the several factors of acid excretion in nephritis. WALTER W. PALMER AND LAWRENCE J. HENDERSON. *Arch. Intern. Med.* 16, 109-31(1915).—"The cases of nephritis studied are divided into 2 groups: (1) Cases in which the vol. of urine is large, its acidity intense and the total acid excretion much diminished (due to very low urinary NH_3). "In this group the later stages of glomerulonephritis predominate. It is usual to find high non-coagulable N, a much reduced phenolsulfonephthalein excretion, a high blood pressure, large amts. of albumin and a low sp. gr. of the urine." (2) Cases in which the vol. appears to be almost normal, acidity high, total acid excretion low, but not infrequently normal. The degenerative type of nephritis and earlier stages of glomerulonephritis occur more frequently in this group. The non-coagulable N, though often increased, is not always strikingly so. Phenolsulfonephthalein excretion is moderately, or even markedly, diminished. Blood pressure varies widely and albumin occurs in small amts. The sp. gr. of the urine is higher than in the first group. Cf. C. A. 8, 1982.

I. GREENWALD.

The Wassermann reaction in typhus exanthematicus. CONSTANTIN DELTA. *Centr. Bakt. Parasitenk., I Abt.* 76, 50-4(1915).—"The Wassermann reaction is constantly positive in typhus exanthematicus with either syphilitic or typhus antigen. It is negative at first, positive during defervescence, then negative after 2 mos.

JULIAN H. LEWIS.

The transmission of immunity against fowl cholera from mother to offspring. PHILIP B. HADLEY. *Centr. Bakt. Parasitenk., I Abt.* 76, 196-208(1915).—"This paper presents data on the inheritance in rabbits of immunity to infection with the bacterium of fowl cholera (hemorrhagic septicemia). It is demonstrated (1) that, contrary to previous results of other workers, female rabbits immunized by inoculation with a certain avirulent strain of fowl cholera bacterium, are able to transmit to their offspring a high degree of resistance to a virulent culture; (2) that some mothers are able to produce such immune offspring for more than 2 yrs. and 3 mos. after the date of immunization; (3) that resistance is not transmitted by immune males; (4) that as a rule the inherited resistance of the offspring does not endure for more than 40 days; (5) that this transient, inherited, passive resistance can be transformed into a durable active immunity by inoculating the young animals, sometimes within the first 40 days of life with small amts. of virulent culture; (6) that the method of immunity-transmission may have a practical application in the protection of animals against infection. JULIAN H. LEWIS.

The presence of so-called complement in milk. R. T. HEWLETT AND CECIL REVIS. Univ. London. *Centr. Bakt. Parasitenk., I Abt.* 76, 337-47(1915); cf. C. A. 9, 1197.—"In the case of mastitis milk, amboceptor may be present as well as complementary substance, but this would not be detectable in admixture with other milk. Colostrum gives evidence of its presence in 5% diln. with other milk. Even in the slighter forms of mastitis, complementary substance is present in the milk long after subsidence of the inflammatory condition. There is no connection to be traced between the number of cellular elements and the presence of the complementary substance, though the appearance of the latter is often accompanied by a rise in the number of the former. The above mentioned hemolytic system is of extraordinary delicacy in the case of milk. There is some doubt as to the true nature of the complementary substance in milk.

JULIAN H. LEWIS.

The biological reactions of the vegetable proteins. VI. The anaphylactic reaction with so-called proteoses of various seeds. H. GIDEON WELLS AND THOMAS B. OSBORNE. *J. Infect. Dis.* 17, 259-75(1915); cf. *C. A.* 8, 1824.—Substances that correspond in their solubility to animal proteoses obtained by dialyzing NaCl soln. exts. of seeds are distinguishable by means of the anaphylactic reaction from the other reserve proteins of the seeds. The proteoses obtained from different seeds and grains are also quite distinct from one another. They exhibit strong anaphylactic properties and cause very severe anaphylactic intoxication when injected into sensitized guinea pigs, even in minute doses (0.001 to 0.0005 g. being fatal doses with some of them). Their activity in this respect resembles that of the sol. animal proteins, such as egg-white, serum, etc., and greatly exceeds that of any of the other vegetable proteins (globulins, alc.-sol. proteins, etc.) which have been studied. This high anaphylactic activity seems to depend upon their great solubility in the body fluids. Their activity is not destroyed by heating to 100° for 1/2 hr., presumably because of their incoagulability. In their anaphylactic power these natural proteoses differ sharply from proteoses obtained from animal proteins by digestion with enzymes, or by chem. hydrolysis, such artificial products being almost, if not entirely, non-anaphylactogenic. Furthermore, those products of hydrolysis which result from heating vegetable proteins with acids, with H₂O under pressure, or by peptic digestion, have, so far as they have been tested, no anaphylactic properties. From these facts it would seem that the vegetable proteoses belong to a group of proteins which are chemically different from any heretofore recognized. They resemble highly sol. native proteins in their anaphylactogenic capacity, and are probably quite as complex in their chem. constitution. Their designation as proteoses is consequently improper. This differentiation of so many of these proteose preps. from the other proteins in the same seed is a striking example of the fact that the specificity of the anaphylaxis reaction is not dependent on biologic origin, but on chem. constitution. These expts. show also that these sol. proteins, which occur in the seeds of so many species of plants, are as distinct from one another as are the other more abundant proteins. The results described in this paper demonstrate that anaphylaxis furnishes a useful means for detg. the purity of protein preps. obtained from plant exts., in so far as contamination with the other proteins of the same seed are concerned.

JULIAN H. LEWIS.

Sensitization by protein cleavage products. E. HAILER. *Arb. kais. Gesundh.* 47, 527-40(1915).—Guinea pigs may be sensitized toward various sera by the use of protein cleavage products obtained by the digestion of beef or pork with steam, acids, or peptic or tryptic enzymes, also by the use of various com. exts. or preps. either containing coagulable protein or not. However, such sensitization is not specific, even when a sp. protein is present in the sensitizing serum. This confirms the observations of Uhlenhuth and Haendel. Cf. *C. A.* 4, 1198.

BERNARD RAYMUND.

Chemical constituents of water and diseases (MORGEN) 14.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Is strychnine an antagonist of stovaine? ITALO SIMON. Univ. Padua. *Arch. farm. sper.* 19, 412-22(1915).—Injection of strychnine does not increase the resistance of rabbits to stovaine, nor modify the behavior of the respiratory center toward this drug.

A. W. DOX.

A case of fatal poisoning by the American water hemlock. ANON. *Pub. Health Bull. of Mass. Board of Health* 2, 50-2(1915).—Symptoms are nausea, vomiting, vertigo, widely dilated pupils, convulsions, loss of consciousness, quickly passing into coma and rigor mortis. All of this happens in an hour. An ext. was made of the root of the plant and from its action on a frog it was found that a poison of the picrotoxin or cicu-

toxin group was present. This plant is sometimes taken for "*Sium cicutaefolium*," which is eaten by children. They differ in that the stems of the poisonous plant are quill-like while those of "*Sium*" are strongly corrugated or furrowed. Because of odor and texture, it is also sometimes mistaken for parsnips, artichokes, sweet cicely, horseradish or other edible roots.

J. GAUB.

The relation of the purgative action of magnesium sulfate to peristalsis and the general law of crossed innervation. S. J. MELTZER. Rockefeller Inst. *Arch. Intern. Med.* 15, 955-63 (1915); cf. *C. A.* 5, 711; 8, 2575, 3695.—There are 2 phases to peristalsis: (1) contraction of a portion of the intestine; (2) relaxation of that portion of the intestine immediately below the contracted part. $MgSO_4$ given intravenously or introduced directly into the lumen of the intestine of rabbits inhibits peristalsis. It is believed to increase the intensity of the inhibitory phase. The combination of a substance having this action with one, such as ergot, that augments the contractile phase of peristalsis, leads to a very rapid peristaltic wave. It is suggested that when $MgSO_4$ is given by mouth some Na_2SO_4 is formed (by interaction with $NaCl$). This increases the active phase of peristalsis; the remainder of the $MgSO_4$ intensifies the inhibitory phase. The consequence, as in the case of ergot and $MgSO_4$, is a very rapid peristalsis or purgation.

I. GREENWALD.

Digitalis dosage. CARY EGGLESTON. Cornell Univ. Med. College. *Arch. Intern. Med.* 16, 1-32 (1915).—"The cat method of standardization of digitalis yields results on which the dose for man can be based. The av. therapeutic dose of digitalis, given orally to man in the form of the tincture or infusion, is 0.146 "cat unit" (cat unit = the amt. of the drug which is just sufficient to kill 1 kg. of cat when slowly and continuously injected into the vein), or about 0.146 cc. of an av. high-grade tincture, per lb. of body wt., as established by 33 observations. Fifteen observations have established 0.066 cat unit or 0.023 mg. per pound as the av. therapeutic dose of cryst. digitoxin. In approx. 0.5 of a total of 48 courses of administration of either digitalis or digitoxin, full therapeutic effects were secured with doses falling within 15% above or below the av. dose. Doses considerably larger than the av. were taken in 17 instances without the production of more than mild toxic symptoms. The activity of the prep. of digitalis has no material influence on the dose required in terms of cat units. Age, sex and cardiac condition do not seem to influence the size of the dose required. Both digitalis and digitoxin are probably rapidly and fairly uniformly absorbed from the alimentary canal of men, but digitalis is less completely absorbed than is digitoxin. Stropanthus, the stropanthins, ouabain, true digitalin and some others are poorly or irregularly absorbed when given by mouth or to the higher animals and are unsuitable for therapeutic use in this way."

I. GREENWALD.

The clinical action of veratrum. RUSSEL J. COLLINS. *Arch. Intern. Med.* 16, 54-8 (1915).—"The therapeutically effective dose of the tincture of *Veratrum album* for adults ranges from 30 to 75 minims. Clinically, the effects of veratrum resemble the pharmacologic effects, and consist of a slowing of the pulse-rate amounting to from 12 to 42 beats per min. and a fall of systolic blood pressure amounting to about 39, of the diastolic, 32 mm. The 2 hypertension cases showed a fall of systolic blood pressure amounting to about 49 mm., of the diastolic, of about 8 mm. The circulatory effects produced by veratrum take place independently of the "toxic" symptoms such as nausea and vomiting."

I. GREENWALD.

The symptoms of urined poisoning. FRANK A. HARTMAN. *Arch. Intern. Med.* 16, 98-108 (1915); cf. *C. A.* 8, 3816.—Urined is toxic to frogs, lizards, mice and man. The lethal dose in frogs is from $1/800$ to $1/800$ of the body wt. Of this, most is not absorbed, so that the true lethal dose is probably much smaller. "The symptoms produced by urined ordinarily are: nausea, headache, loss of appetite, heaviness of the stomach

after meals, twitching, irritability of temper, mental dullness, physical weariness, drowsiness, dyspnea, convulsions and a state of non-irritability. The symptoms of urino poisoning resemble the nervous symptoms of uremia. Urino retention, therefore, might partly account for these nervous symptoms." I. GREENWALD.

The influence of salicylates upon the uric acid concentration of the blood. MORRIS S. FINE AND ARTHUR F. CHACE. *J. Biol. Chem.* 21, 371-5(1915).—The administration of Na salicylate or of aspirin lowered the concn. of uric acid in the circulating blood. Except in 1 case, the concn. of uric acid in the blood returned to its former level after medication ceased. I. GREENWALD.

Quantitative criteria of antagonism. W. J. V. OSTERHOUT. *Botan. Gas.* 58, 178-86(1914).—The method of mixing equally toxic solns. furnishes the best criterion of antagonism, since it is known at the outset just what effect each mixt. must have, provided there is no antagonism. Mixts. of 2 equally toxic solns. must have precisely the same effect on growth as the pure solns. themselves, provided that the effects of the salts are additive. If antagonism exists there is increased growth in the mixts. The amt. of this increase, expressed as % of the growth obtained in the pure solns., is a means of measuring antagonism. The most reliable results are obtained by the use of uniform material and by taking for measurement only such parts as come into immediate contact with the soln. B. HOROWITZ.

Anesthesia by phenylethylmalonylcarbamide. W. L. SYMES. *J. Physiol.* 49, 126-32(1915).—Physiol. action of the Na salt of methylethylmalonylcarbamide (luminal) is described for cats. 0.2 g. per kg. body wt. produces prolonged anesthesia, which reaches a max. after several hrs. There is no marked diuresis. Cats may be kept unconscious for days and recover completely. The anesthetized animal is markedly poikilothermic; hence the temp. of the room must be carefully regulated during the expt. Rabbits may be rapidly anesthetized by intravenous injection of a 10% soln. J. F. LYMAN.

Note on the treatment of the symptoms arising from inhalation of irritant gases and vapors. W. L. SYMES. *Brit. Med. J.* 1915, II, 12-3.—A preliminary report. Br vapor was administered to pithed cats under artificial respiration: The effect of the vapor is rapid, or gradual, obstruction of trachea. In some cases profuse broncharrhea appeared in the course of an hour. Little or no relief is afforded by intravenous injection of broncho-dilator drugs, but inhalation of same or similar drugs moderated symptoms. Amyl nitrite, atropine, adrenaline, stramonium (leaf infusion), lobelia, tobacco, opium and CHCl_3 were tested. Stramonium was the most successful. A. H. RAHE.

Action of the opium alkaloids, individually and in combination with each other, on the coronary artery and the coronary circulation. D. I. MACHT. Baltimore. *J. Am. Med. Assoc.* 64, 1489-94(1915); cf. *C. A.* 8, 175, 1466, 1997, 3694.—Rings about 2 mm. thick from the fresh coronary arteries of the pig were used. Two, 3 or 4 of these are joined together tandem fashion, and suspended in a glass chamber filled with Locke soln. at 37°; through this a const. stream of O is kept bubbling. In case of narcotine, Ringer soln. must be used in place of the alk. Locke which ppts. the alkaloid. Great care must be taken to keep the temp. and flow of O constant. The Locke soln. should be prepd. with glass-distd. water to avoid metals in soln. The prep. is then weighted by trial; the optimum condition of tonus for each prep. has to be detd. by selecting the proper wts. The test is then made by removing the Locke soln. and introducing in its place the substance to be tested dissolved in oxygenated Locke soln. at 37°. The alkaloids tested were morphine, narcotine, papaverine, codeine, narceine, and thebaine. The first three produced the greatest dilatation of the coronary, increasing in the order indicated. Codeine produced much less dilation, narceine and

thebaine practically none. Heroin behaved like codeine. Comparatively small therapeutic doses of the alkaloids produced relaxation. In the case of papeverine-HCl, 1 mg. in 100 cc. of soln. gave a distinct dilation. A combination of morphine and narcotine produces much less relaxation of the coronary artery than that produced by each of them individually. It is suggested that this antagonism is due to the different molecular structures of these alkaloids in their respective pyridine-phenanthrene and benzyl-isoquinoline groups. Expts. were made on excized hearts, and on the intact animal (cat). Caffeine singly was found to dilate the coronary artery, and this action was not antagonized by the opium alkaloids. L. W. RIGGS.

Lead neuritis from cosmetics. L. R. SANTE. St. Louis. *J. Am. Med. Assoc.* 64, 1573-4(1915); cf. *C. A.* 9, 1204.—Cases of poisoning by the use of "flake white" as a cosmetic are reported. L. W. RIGGS.

Distribution of arsenic in liver tissue in cases of poisoning. LEON A. RYAN. *J. Am. Chem. Soc.* 37, 1959-60(1915).—Analyses of the left lateral, left + right central, and caudate + right lateral lobes of the livers of dogs to which Na_3AsO_3 had been administered subcutaneously or in the food until death resulted showed that the As was uniformly distributed throughout the liver tissue. CHAS. A. ROUILLER.

Two poisonous plants. A critical review and experimental study of the yew (*Taxus baccata*) and the bryony (*Bryonia alba* and *B. dioica*). DIETRICH JENSEN. *Rostock Inst. Pharm. physiol. Chem.*, Separate 1-57(1914); through *Chem. Zentr.* 1915, I, 211-2.—The pulp of the ripe fruit of the yew is non-poisonous; the kernel contains the taxin. This substance is pptd. from its satd. soln. in very dil. NaCl soln., by NaCl, NH_3 , NaOH, phosphotungstic acid, phosphomolybdic acid, potassium mercuric iodide, KI_3 , Esbach's reagent, AuCl_3 and $(\text{NH}_4)_2\text{SO}_4$. With concd. H_2SO_4 it gives a red color and with Killiani's reagent a red ring; KMnO_4 is decolorized in both acid and neutral soln. In CHCl_3 with a layer of concd. H_2SO_4 a brown ring is formed. The unripe fruit is perhaps more poisonous than the ripe. Taxin is not toxic to fish. Rabbits, guinea pigs, and cats, if the dosage is cautiously increased, can stand many times the lethal dosage subcutaneously without harm. These animals thus become comparatively immune to this poison very quickly. Game and cud-chewing domestic animals stand moderate amts. of yew needles without harm; horses and other solipeds, though more susceptible, likewise soon easily accustom themselves to taxin. It may be exdtd. from the urine, into which it passes unchanged, by Et_2O , after adding Na_2CO_3 . The action of taxin consists in motor excitation of the central nerve system, followed by paralysis. Fresh bryony root is much more active than the dried, and the former gives a good yield of active substance only in late autumn. Two glucosides can be obtained from the roots gathered in October; *bryonin* (sol. in H_2O), which is inactive, and *bryonidin* (insol. in H_2O), which paralyzes the nerve system when parenterally applied. Taken internally, bryonidin may act as a purgative. *Bryonia* does not merit therapeutic use. NORMAN A. SHEPARD.

Various cases of poisoning. FLEISSIG. *Schweiz. Apoth. Ztg.* 53, 252-3(1915).—Kanngieser records the symptoms of exptl. self-poisoning with berries of *Daphne mezereum* and the use of uzara as antidote. R. Beck reports on poisoning by nutmeg, A. Guth (*Corresp. Bl. f. Schweizer Aerzte* 1915, No. 9) on a toxic effect on the kidneys, bladder and urethra by a certain porous plaster. Other poisonous principles reported on are fungi (Roch), *Solanum nigrum* (Kanngieser and Hager) and *Euphorbia lathyris* (H. Wegelin). S. WALDBOTT.

Toxic symptoms among workers in calcium cyanamide factories (KOELSCH) 4.

I. ZOÖLOGY.

R. A. GORTNER.

Formation of fats from proteins in the eggs of fish and amphibians. J. F. Mc-

CLENDON. Univ. Minn. *J. Biol. Chem.* 21, 269-81(1915).—"During the development of the *Cryptobranchus* egg there is an increase in the fatty acids of about 8%. During the development of the brook-trout egg this increase is about 5.6%. In these eggs the vitellin is the chief reserve material and it seems probable that it is transformed into fatty and other substances."

I. GREENWALD.

Conditions of activation of unfertilized starfish eggs under the influence of high temperatures and fatty acid solutions. RALPH S. LILLIE. *Biol. Bull.* 28, 260-303 (1915).—In order to induce favorable development an exposure of 3-4 times the minimum for membrane formation (*e. g.*, 7-8 min. at 32°) is required; more prolonged exposures are followed by failure to develop. Brief exposure to *N*/260 butyric acid causes membrane formation followed by a breakdown; longer exposures cause cleavage and development to larval stages, and still longer exposures produce cytolysis without development.

B. HOROWITZ.

Absorption of fat by fresh water mussels. E. P. CHURCHILL, JR. *Biol. Bull.* 29, 68(1915).—The first of a series of papers in which C.'s object is to state whether or not animals living in water use dissolved food from the surrounding medium in addition to "formed" food, and also whether, if such dissolved food be used, it is absorbed by the alimentary tract alone or to some extent by the epidermis. He found that fat dissolved in water is absorbed by fresh-water mussels, through the epithelium of the intestine, and probably also by that of the gills, mantle and foot. The fat is transported both by the blood corpuscles and by the plasma directly.

B. HOROWITZ.

Respiratory function of the air stores carried by some aquatic insects (Corixidae, Dytiscidae and Notonecta). RICHARD EGE. *Z. allgem. Physiol.* 17, 80-124(1915).—The air store carried by some air-breathing aquatic insects has a respiratory and not a hydrostatic function alone. When the O pressure in the supply is lowered, O must diffuse into it on account of the O tension-difference between the air and water. The amt. of O that diffuses into the animal's supply of air depends on the tension-difference and on the area of the free surface of the supply. The surface through which the invasion takes place is, in the insects examined, so considerable that the O invasion is able to maintain the life of the animals, even at a temp. of 15-20°. As the CO₂ produced by the animal diffuses out much more rapidly than the O diffuses in, a tension-difference is established for N. N therefore diffuses from the supply of air into the water. During the stay of the animal in the water, the supply of air therefore decreases and finally disappears. This is the chief reason why the animals cannot live indefinitely in the water.

B. HOROWITZ.

Autolysis and involution. MAX MORSE. *Am. J. Physiol.* 36, 145-52(1915).—Tails from involuting and non-involuting frog larvae underwent autolysis at equal rates as shown by N not pptd. by tannic acid and by amino acids produced; hence it appears that autolysis is not accelerated in the atrophying tissues of the larval frog.

J. F. LYMAN.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Tamarind sirup. W. C. TABER. *J. Ind. Eng. Chem.* 7, 607-9(1915).—Six sirups were prepared and analyzed. Organoleptic tests agree closely with the opinions of the best manufacturers that 2 lbs. of whole tamarinds to the gal. are necessary to produce the distinct flavor and desirable degree of acidity.

ISADOR MILLER.

Hydrolysis of sugar solutions under pressure. W. S. HUBBARD AND W. L. MITCHELL. *J. Ind. Eng. Chem.* 7, 609-10(1915).—An attempt has been made to det.

under what conditions hydrolysis of sugar (for the prepn. of invert sugar sirups for industries requiring a heavy sirup) can be carried on successfully without caramelization.

ISADOR MILLER.

Concise group method for the detection of gelatinizing agents, pasty material and thickeners used in food products. L. A. CONGDON. *J. Ind. Eng. Chem.* 7, 606-7 (1915).—C. divides all the above products into 6 groups according to the reagent (reactions given) used in their detection: (1) I soln.; (2) Millon's or Stoke's reagent ($\text{HgH}(\text{NO}_2)_2$); (3) concd. soln. Na borate; (4) soln. of NaOH; (5) soln. of HgCl_2 ; (6) Schweitzer's reagent (soln. of cupra-ammonia).

ISADOR MILLER.

The cause of dark color in canned corn. W. D. BIGELOW AND H. M. MILLER. Research Lab., National Canners Assoc., *Bull.* 6, 7 pp. (1915).—The cooker and filler used in canning corn sometimes is not completely tinned. When for any reason a period of several days elapses without the app. being used, a film of oxide appears to form; this is invisible, but yields a trace of Cu to the first corn passing through it, probably because of the salt that is added to the corn. This Cu combines with H_2S (always formed in the cooking of foods containing nitrogenous material), with the formation of CuS. The presence of 0.001% CuS gives corn a preceptibly dark color, while 0.003% makes it practically black. A method for obviating the difficulty is suggested.

The relation of the refraction, specific gravity and solids in tomatoes and tomato pulp. W. D. BIGELOW AND F. F. FITZGERALD. *J. Ind. Eng. Chem.* 7, 602-6 (1915).—As a result of the exam. of a considerable number of fresh and canned tomatoes, and of pulps made up under known conditions, tables have been constructed to facilitate analytical work. The generalizations given below are within the limits of analytical error. The filtrate referred to is obtained by throwing a sample of tomato pulp, or crushed tomato product, on a folded filter. Raw tomatoes should be cooked previously in a reflux condenser. The solids are determined by drying *in vacuo* at 70° and under atmospheric pressure at the temperature of boiling water; solids of pulp *in vacuo* = solids of pulp at atmospheric pressure $\times 1.085$; solids of pulp *in vacuo* = solids of filtrate *in vacuo* $\times 1.12$; solids of filtrate *in vacuo* = solids of filtrate at atm. pressure $\times 1.125$. From the sp. gr. of the filtered liquid at 20° the % of solids of the pulp (not of the filtrate) may be ascertained from the Windish wine table (Table V, *Bull.* 107, Bureau of Chem.). The figure 0.05 should be deducted from the percentage of solids given in that table. The solids of the filtrate may be ascertained from the index of refraction, using Wagner's table for beer and wine ext. This table is applicable without correction to the juice of fresh or canned tomatoes. When applying it to the filtrate from pulp of the usual concn., the figure 0.17 should be deducted from the % of solids as given. If the product has been salted, the NaCl should be detd. and a corresponding correction made in the refractive index.

Carrying over of silicic acid in milk by sterilization in glass flasks. B. PRYL. *Arb. kais. Gesundh.* 48, 321-9 (1915).—A process was devised for the detn. of minute amts. of SiO_2 in milk. Using this method tests were made on the amt. of SiO_2 in raw milk and milk which had been sterilized in the usual manner in glass bottles. While 500 cc. of the original sample of milk contained from 0.8 to 1.1 mg. of SiO_2 , the increase in SiO_2 in milk which had been heated in previously used glass bottles amounted to only 0.0 to 0.7 mg. Unused bottles employed for the first time yielded 0.2 and in the case of cheap bottles 13.2 mg. SiO_2 to 500 cc. of milk. These amts. of SiO_2 are negligible as compared with the amts. taken by children in the form of barley water, infants' foods, spinach, etc. Comparatively speaking the amts. of SiO_2 taken by adults in their food are quite appreciable.

C. A. NOWAK.

Studies relating to the chemistry of milk and casein. New York Agr. Expt. Sta., *Tech. Bull.* 37, 3-11(1914). 1. The cause of acidity of fresh milk of cows and a method for the determination of acidity. LUCIUS L. VAN SLYKE AND ALFRED W. BOSWORTH. 2. The phosphorus content of casein. ALFRED W. BOSWORTH AND LUCIUS L. VAN SLYKE. See C. A. 8, 3663. 3. The action of rennin on casein. II. ALFRED W. BOSWORTH. See C. A. 9, 810.—The acidity of fresh milk is due to the presence of acid phosphates. To det. the acidity, the Ca must be removed previous to titration by treatment of 100 cc. of milk with 2 cc. of satd. soln. of (COOK).

R. C. ROARK.

Examination of evaporated milk. W. D. BIGELOW AND F. F. FITZGERALD. Research Laboratories, National Canners Association, *Bull.* 5, 23 pp.(1915).—The results are given on collaborative work on several methods for the detn. of fat in evapd. milk. The Adams method is only of value from a historical standpoint. If the fat obtained by it is purified by soln. in petr. ether, the results are always low. The Paul method is unreliable for the same reason. "On the whole, this method is long and tedious, and the results are unsatisfactory." The Babcock method and two modifications, which were studied, were found to be only approx. It is pointed out that the method usually employed for reading the fat column in the Babcock tube (reading over all) gives too high results with evapd. milk. The Röse-Gottlieb method alone was found to give accurate results.

Hydrocyanic acid content of bitter and sweet cassava. A. E. COLLENS. Dept. Agr., Trinidad and Tobago, *Bull.* 14, 54-6(1914); *J. Soc. Chem. Ind.* 34, 630.—The following quantities of HCN were found in (a) sweet and (b) bitter cassava plants, the detns. being made immediately after the plants had been dug up: Leaves, (a) 0.0162, (b) 0.041; peel of stem, (a) 0.043, (b) 0.113; pith of stem, (a) 0.019, (b) 0.076; edible portion of root, (a) 0.0048, (b) 0.053%. The HCN content of different parts of the freshly dug roots was the same, but after keeping for 3 days the upper part of the sweet roots contained about twice as much as the bottom portion; loss of water during air-drying also caused the HCN content to increase. When sweet cassava was boiled with water for 1 hr., or roasted, no HCN was developed.

E. J. C.

Baking without grain flour. A. FORNET. Berlin. *Chem. Ztg.* 39, 388(1915).—Potato starch or rice starch used as a substitute for wheat flour in baking, gives a product which is not light and porous, because the dough is not sufficiently elastic and tough to retain the CO₂ during baking. The "Versuchsanstalt für Getreideverarbeitung" has overcome this difficulty by adding materials which give to the dough physical properties similar to those of gluten. (It is not stated what those substances are.) The product is very similar to wheat bread in appearance and taste. Analysis gave H₂O, 39.25; ash, 3.43; fat, 4.35; crude fiber, 0.32; protein, 2.28 and starch, 50.37%.

J. H. MOORE.

Catalase reaction of milk. H. B. TAYLOR. *Proc. Roy. Soc. N. S. Wales* 48, 319-32(1914).—T. discusses the action of milk and an active product obtained from it on H₂O₂. Two methods of study were used. The first, which is suitable for work with milk and H₂O₂, consisted in treating a definite vol. of a mixt. of milk and H₂O₂ at any stage of its reaction, with H₂SO₄ which stops all action and ppts. the caseinogen. The method is as follows: Treat 5 cc. of a mixt. containing 15 cc. 0.1 M H₂O₂ and 50 cc. of milk with 20 cc. 0.2 N H₂SO₄. Filter and analyze the filtrate for H₂O₂ colorimetrically by comparison with a standard soln. of H₂O₂, Ti sulfate being used for the color indicator. Tables are given showing the effect on the rate of decompn. of H₂O₂ when milk is present. The second method is intended for use with pure catalase prepd. from milk. To prep. the soln. of catalase add to 500 cc. of milk HOAc to ppt. the caseinogen; with NaOH make alk. to methyl red and acid to phenolph and filter; treat

the filtrate with 800-900 cc. 90% alc. Filter off the ppt., free from alc. by drying *in vacuo* and treat with H_2O in presence of $CHCl_3$. The resulting soln. is used directly or after dialyzing through parchment paper. Increasing concn. of H_2O_2 decreases the rate at which it is decompd. by the catalase. Increasing temp. increases the rate of decompn. up to an optimum of about 25° and then the rate decreases, due to the destruction of the enzyme by higher temps. The rate of destruction is increased by increasing concn. of H_2O_2 and by increasing temp. At 15° it is $2\frac{1}{2}$ times and at 50° over 200 times as great as at 0° . KCN and HCN decrease the activity of the enzyme, but increase its resistance to destruction by H_2O_2 . Numerous tables show the exptl. data and the velocity consts. of decompn. of H_2O_2 and of destruction of the catalase under varying conditions.

P. J. DONK.

The manufacture of condensed milk, milk powders, casein, etc. R. T. MOHAN. *Chem. Eng.* 22, 11-5(1915); see C. A. 9, 1515.

E. J. C.

Quantitative determination of the amino acids of feeding-stuffs by the Van Slyke method. H. S. GRINDLEY, W. E. JOSEPH AND M. E. SLATER. *J. Am. Chem. Soc.* 37, 1779-81(1915).—The V. S. method applied to cottonseed meal, tankage and alfalfa hay gave the following resp. results, expressed in % of the total N of the feeding-stuff: Ammonia N, 10.45, 6.58, 8.44; melanine N, 7.78, 4.40, 15.79; arginine N, 19.52, 14.15, 7.68; cystine N, 0.65, 1.28, 0.88; histidine N, 5.47, 4.97, 7.44; lysine N, 4.78, 7.48, 4.10; amino N in filtrate from bases, 42.82, 52.39, 44.02; non-amino N in filtrate from bases, 5.43, 7.27, 9.79. A table is also reproduced, giving the results in % of the feeding-stuff.

CHAS. A. ROUILLER.

Tests of the Humphries-Thomas method for the moisture treatment of grain products. J. BUCHWALD AND M. P. NEUMANN. *Z. ges. Getreidew.* 5, 24(1913); *Chem. Tech. Rept.* 38, 48(1914).—The baking properties of flour are improved by exposing it to a current of warm moist air and adding at the same time Na_3PO_4 and malt ext. Flour with more than 15% H_2O does not keep well.

H. L. OLIN.

Determination of lint in cottonseed meal. R. N. BRACKETT. Clemson College. *J. Ind. Eng. Chem.* 7, 611-2(1915).—Soln. by $ZnCl_2$ is employed. ISADOR MILLER.

Ger., 282,799, Sept. 30, 1913. F. MÜLLER. Machine for sepgg. the press mats from oil cakes.

Ger., 282,973, July 3, 1913. K. M. SPENGLER. Manuf. of a cola preparation. The roasting of the cola bean with a view to obtaining a permanent prepn. results in the conversion of a portion of the alkaloids (caffeine with some theobromine) from the combined to the free form, which is less active. This conversion is prevented in the improved process by fermenting the ground beans in their own juices for a time before roasting. At the same time the volatile oils, which give rise to the unpleasant taste, are removed. In carrying out the process the fresh beans are first ground and allowed to lie in heaps for 3-6 days to ferment in their own juices. The resulting product is then subjected to a roasting process at $180-200^\circ$ until the granules have been thoroughly roasted. The product thus obtained has a mild aromatic taste and does not differ in its action, in any way, from the fresh bean, but may be kept for a year.

The prepn. is used by boiling up in hot H_2O , and thickening the resulting liquor by the addition of sugar. The ext. can, moreover, be used directly, as coffee or tea, for a beverage.

Ger., 283,044, July 2, 1912. A. SAMUEL. In mfg. artificial sausage skins, a suitable absorbent material, such as a fabric, or the like, having the form of the intestine, is impregnated with fresh flesh. Raw meat is ground repeatedly until it forms a thin slurry; a suitably shaped skin of fine mull, or the like, is coated with this slurry, and the impregnated fabric is dried. The slurry may be further dild. with H_2O , and binders or preservatives may be added. The blood plasma and serum of freshly slaughtered animals may be used as diluent and binder. This product does not crack and upon drying the sausage it does not wrinkle. Any desired form may be given to it. Smoking is facilitated and the material is cleaner than the natural skin.

Ger., 283,346, Sept. 4, 1912. A. QVALE. Preserving fish and other foodstuffs by packing in shredded peat which has been taken from a depth. The preservative constituents of peat are missing from the surface layers.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Report of committee on water purification. W. H. DURBIN, Chairman. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 50-56.—The final report of the N. E. W. W. A. Comm. on Stan. Statistics is referred to as applying to the Evansville filter plant. Very little data are given. D. K. FRENCH.

The Madison, Ind., water supply. J. W. MOORE. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 87-90.—The first supply was taken direct from the Ohio River, then from the infiltration wells in the bed of the river, now from wells sunk near the bank of the river. The first two methods were unsatisfactory from a sanitary point of view. The water at present is pronounced good. D. K. FRENCH.

Determination of reaction in waters. H. KLUT. *Wasser u. Abwasser* 9, 337-41 (1915).—A critical discussion (nothing new) of the use of various indicators such as litmus, rosolic acid, Congo red, methyl orange and phenolphthalein. A. L.

Boiler waters of Iloilo province. G. W. HEISE. *Philippine J. Sci. (A)* 10, 75-9 (1915).—Analyses of water for boiler purposes from 34 sources are given. It is concluded that much better supplies are available than are being used at the present.

W. F. LANGEЛИER.

Water supply for city of Iloilo. G. W. HEISE. *Philippine J. Sci. (A)* 10, 65-72 (1915).—Three proposed sources of supply were investigated. Artesian water contains from 300 to 1800 p. p. m. Cl. Tigon River if impounded would furnish abundance of good water but estimated cost of the project is too high. Analyses of water from Tigon R. indicate turbidity 0, color 0, residue 390, Cl 16, SO_4 54, Fe 0.7, alkalinity 50 p. p. m. Spring water from upland sources of Guimaras Is., 3 km. across the straits, is of good quality and could be delivered to consumers at reasonable cost.

W. F. LANGEЛИER.

The new water supply of the fishing harbor at Ymuiden (Holland). ANON. *J. Gasbel.* 58, 250-3 (1915).—The plant consists of an intake, an iron removal app. and filter house, a clear water reservoir, and a water tower. A max. of 100 cu. m. per hour can be furnished. ARTHUR LEDERER.

The effect of filtration and sterilization on typhoid fever in Philadelphia. F. D. WEST. *Munic. J.* 39, 111-2 (1915).—The bacterial results at the Torresdale plant, together with typhoid statistics, demonstrate conclusively the benefits of water disinfection. ARTHUR LEDERER.

Akron's water purification plant. *Munic. J.* 38, 725-8(1915).—This rapid filter plant handles a population of 75,000. The novel feature is the filter bottom of the Wheeler strainer type, using graded spherical balls in pyramidal cups 8.8 in. sq. on the base. A brass tube $\frac{3}{4}$ in. diam. enters the apex, the jet of water lifting the balls slightly during wash. L. PEARSE.

Slow sand filtration of water. JOSEPH RACE. *Can. Engr.* 28, 595-9(1915).—Slow sand filtration depends on mechanical, physical and biochem. action. The changes effected chemically, largely reduction of free NH_3 , are slight. The bacterial reduction should be high. A table shows the relation between rate of filtration and removal of bacteria. Slow rates prolong runs, but the quantity filtered remains const. The rate of 6.05 mil. gal. per acre per day appears economical. The rate of filtration should be kept const. Color is not affected by slow sand filters. Excessive turbidities require use of a coagulant. L. PEARSE.

The war and potable water. E. A. MARTEL. *Rev. hyg. pol. sanit.* 37, 449-90 (1915).—M. discusses the contamination of subterranean waters, inhumation and exhumation on battle fields, sanitation of devastated regions, and safeguards of potable waters. W. H. FRY.

The Moor water of Schwartau, its composition and use, Niederstadt. Z. öffent. Chem. 31, 71-3(1915).—This is a deep brown, clear water (sp. gr. 1.0030), which gives no ppt. on standing. It is recommended as a bath water. In 1 liter there is 1.7592 g. of residue composed of SiO_2 0.0245, Fe_2O_3 0.0154, CaSO_4 0.0812, K_2SO_4 0.0256, Na_2SO_4 0.0208, KCl 0.0444, NaCl 0.0348, MgCO_3 0.0268, K_2CO_3 0.6350, Na_2CO_3 0.4870, humic acid 0.3637 g. H. A. LEPPER.

Water works of Valparaiso, Ind. E. L. LOOMIS. *Munic. Eng.* 49, 9-12(1915). ARTHUR LEDERER.

Chemical constituents of water and their relation to non-specific diseases. H. G. MORGAN. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 94-99.—M. describes the relation of alk. earth and other salts in water to such diseases as goiter, kidney and bladder stones, arterio-sclerosis, diarrhea, indigestion, etc., laying special stress upon the subject of goiters. This has been considered more or less of a water-born disease, but investigation has failed to show any decided relation between sol. salts and goiters. A deficiency in I is suggested as the most probable cause. D. K. F.

The standards for drinking waters used in interstate carriers. H. E. JORDAN. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 38-42.—J. discusses and criticizes the recent govt. standards (C. A. 9, 675) and their relation to municipal supplies. D. K. FRENCH.

Potash waste lyes and drinking water. J. H. VOGEL. *Chem. Ind.* 38, 1-5(1915).—A general review and discussion of the permissible limits of the content of waste lyes in drinking H_2O with especial consideration of the recent publications of Gärtner (*Z. Hyg. Infekt.-Krankh.* 79, 1-129 (1914)). F. W. SMITHER.

The utilization of the "upper surface-subterranean" water for bathing purposes. H. KÜHL. *Z. öffent. Chem.* 20, 393-7(1914).—The term "upper surface-subterranean" water is used to designate water of ponds or lakes owing their origin to subterranean streams. Results of chem. and mycological exam. of a water from a lake of this type are given with conclusions drawn therefrom. H. A. LEPPER.

Fat from precipitated muck and the disposal of the residue. H. BECHHOLD. Frankfurt a/M. *Chem. Ztg.* 39, 283-4(1915).—B. discusses the utilization of the fat present in sewage in connection with the war and the great decrease in the amt. of fats and oils at present imported into Germany. It is estd. that each inhabitant contributes 10 g. of fat (in all forms) daily to the waste H_2O of a household, thus making a daily

total of 670,000 kg. for 67 million inhabitants; this fat can only be recovered in case the sewage is collected in settling basins for clarification. The fat which collects upon the surface of the sewage in the settling basin constitutes only a small proportion of the total fat; most of the fat is absorbed by the flocculating, suspended particles of the sewage and thus carried to the bottom of the basin. The fat content of the muck varied from 12 to 22% in different cities. In previous expts. at Kassel the pptd. muck was first dried (after addition of H_2SO_4) and then extd. with benzene; this expt. was an economic failure because of the fuel expense in drying, the muck being especially difficult to dry because of the enveloping layer of adsorbed fat on the particles. In subsequent expts. at Frankfurt a/M, the muck (with the contained H_2O) was treated with a fat solvent, the highest temp. employed in the preliminary treatment of the muck being considerably below 100° ; the muck, after removal of the fat, was passed through presses to remove the remaining H_2O . The muck contained 90-95% H_2O , according to the speed with which the sewage passed through the basin; by careful treatment it was possible considerably to reduce this H_2O content. A brownish black crude fat of the consistency of grease was finally obtained; by distn. under reduced pressure it was possible to obtain a yellow fat which was sepd. by pressing, into approx. 50% liquid olein and 50% solid stearin. The m. p., sapon. no., acid no., I no. (Hübl) and % of unsaponifiable substance of the olein and of stearin were (undetd.), 167.5, 160.5, 62.85, 19.37 and 45.3° , 199.0, 195.2, 25.07, 6.07, resp. The capacity of the muck for retaining H_2O is so greatly diminished in the process of extg. the fat, that the H_2O content may be readily reduced to approx. 50% in the app. employed. The principal value of this partially dried muck is in the production of heat or for fertilizer. H. S. PAINE.

The electrolysis of sewage. E. SCHNECKENBERG. *Elektrochem. Z.* 21, 294-6 (1915).—Data are given showing the disinfecting properties of Cl when added as NaOCl to sewage. The Stahl electrolyzer is built for the purpose of producing NaOCl from NaCl. W. E. RUDER.

The Indianapolis sewage testing station. C. H. UNDERWOOD. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 139-144.—The testing station comprizes an Imhoff tank of reinforced concrete, and is a full sized unit. Dimensions: diam. 24 ft., depth 29 ft. 4 in. from the water level; the bottom is conical. The settling chamber has a capacity of 21,000 gals. and the sludge digestion chamber 47,000 gals. There are also 2 sprinkling filters 16 ft. in diam. The plant is built over the main intercepting sewer and the results of the work have shown the tank to be suitable for preparatory treatment. A 2-hr. rate of operation is considered satisfactory for Indianapolis sewage. Eight-foot filters produce effluents that cause no visible nuisance when mixed with river water. D. K. FRENCH.

Activated sludge in America. W. N. BAKER. *Eng. News* 74, 164-71 (1915).—Notes on the new process of sewage treatment gathered by B. on visits to the several experimental plants. Sewage is aerated in the presence of an accumulation of aerated sludge. There is reason to hope that a high degree of clarification (and perhaps bacterial reduction, when necessary), with a stable effluent and a quick-drying sludge, high in fertilizing value, can be produced by this process. ARTHUR LEDERER.

The sewage disposal works at Fitchburg, Mass. D. A. HARTWELL. *J. Boston Soc. Civil Eng.* 2, 203-22 (1915); cf. *C. A.* 9, 1522.—The disposal works now in operation serve 35,000 population. In Jan., 1915, 68.6% of the suspended solids were removed by the Imhoff tank. The sprinkling filter effluent contained 3.9 p. p. m. of nitrates, and 60% of the daily samples were stable. Owing to the partial completion of the sewer not all the population is yet connected. The total cost exclusive of excavation for the disposal works was \$347,000, or for 55,000 people \$6.31 per capita.

L. PRARSE.

Activated sludge experiments at Milwaukee, Wisconsin. CH. T. HATTON. *Eng. News* 74, 134-7(1915).—Tests of the activated sludge method of sewage treatment are described. A large fill-and-draw tank, and a continuous flow tank of the same size and also two small tanks provided with glass windows are included in the studies which are being made. Methods of air diffusion, vol. and time of air application and cost records are given.

ARTHUR LEDERER.

The purification of industrial wastes. H. KLUT. *Naturwissenschaften* 2, 415-9, 444-8(1914); *Wasser u. Abwasser* 9, 385-8(1915).—K. discusses methods of treatment for wastes produced by several industries. Suspended matter and fibrous material should be removed previous to the discharge of trade wastes.

ARTHUR LEDERER.

Reduction of garbage. ANON. *Munic. J.* 39, 35-9(1915).—The plant on Barren Island, New York, disposes of the garbage of that city by the reduction process. A description of the plant, together with a report on the further elimination of odors, is given.

ARTHUR LEDERER.

Three residential sewage treatment plants near Cleveland. R. F. MACDOWELL. *Eng. News* 74, 56-7(1915).—The first plant consists of a 2-story sedimentation tank and a glass-covered rapid sand filter. The purpose of the glass is to produce heat which aids in drying the surface of the beds and thus makes the scum and grease deposits more readily removable. The total cost of the plant was about \$2,000.00. The second plant consists of screens, a 2-story sedimentation tank, dosing tank and intermittent sand filters. The plant was designed to treat a max. daily sewage flow of 4500 gal. The third plant consists of a septic tank, dosing tank, and sub-surface irrigation. All 3 plants operate successfully and have produced effluents of satisfactory character.

ARTHUR LEDERER.

Sewage disposal in Maryland. *Munic. J.* 38, 842-4(1915).—The need of adequate state supervision is outlined. The organization of sewerage districts is recommended. The state has passed a law (just declared constitutional), giving full powers over water supply and sewerage systems for the construction of which the municipal authorities may issue bonds up to 2%.

L. PEARSE.

Albany's sewage treatment plant. *Munic. J.* 38, 837-40(1915).—Albany (N. Y.) is constructing intercepting sewers, pumping station and sedimentation plant (Imhoff tanks) at a cost of \$1,100,000 to settle the sewage before discharge into the Hudson River. The tanks have a period of detention of 3 hrs. at 30 mil. gal. flow per day.

L. PEARSE.

Garbage and rubbish disposal in Los Angeles. S. C. SIMONS. *Munic. J.* 38, 799-803(1915).—A contractor pays the city 51 cents a ton for garbage delivered at the works. A reduction plant handles about 175 tons daily, on the Cobwell system. The garbage is treated under 85 lbs. per sq. in. steam pressure, with a liquid resembling naphtha to ext. the grease. The tankage is dried and bagged. One ton of green garbage yields 600 lbs. tankage and 85 lbs. grease. The tankage contains 2.68% N, 2% P₂O₅ and 1.9% potash.

L. PEARSE.

Sewage works of Morristown. CLYDE POTTS. *Eng. News* 73, 1105-8(1915).—Morristown had a population of 12,507 in 1910, with a low water consumption of 40 gal. per cap. per day. The plant was designed on a basis of 66 gals. per cap. per day, and 15,000 pop., and comprises (1) a settling tank of capacity 100,000 gal.; (2) 5 contact beds in a pentagon of total area 1.25 acres, each 6 1/4 ft. deep, with 1/2 to 2 in. stone, underdrained; (3) contact bed control housed in; (4) 4 sand filters of total area 1.5 acres. The dried tank sludge contains, in %, N 0.51, total P₂O₅ 0.14, potash 0.10. The effluent has been stable, with a bacterial reduction of 96.8%. The plant cost \$94,889.00.

L. PEARSE.

Refuse incinerator, Florence, S. C. McKEAN MAFFITT. *Eng. News* 73, 1166-7 (1915).—A 12-ton incinerator is used to burn night-soil, garbage and other refuse.

L. PEARSE.

Garbage reduction at Columbus, Ohio, in 1913 and 1914. T. D. BANKS. *Ann. Report*, Columbus, 1914; *Eng. News* 73, 1030(1915).—Tables give detailed figures on itemized costs. A net profit of \$1.226 per ton of garbage was made or \$26,501.57 for the year 1914.

L. PEARSE.

Sewage disposal plant for Akron. ANON. *Munic. J.* 39, 71-4, 112-4(1915).—The plant consists of Imhoff tanks, sprinkling filters, secondary sedimentation tanks and sludge beds. Novel features in details of Imhoff tank construction and in control chambers are shown. There is in addition a garbage reduction plant with a capacity of 25 tons in 8 hrs.

ARTHUR LEDERER.

Sewerage system and sewage disposal farm at Cairo, Egypt. *Eng. News* 73, 1030(1915).—The sewage is lifted by compressed air ejectors in a central station and discharged through a sewer 12 miles long to a sewage farm of 3,000 acres.

L. PEARSE.

Sewage treatment plant for a small sanatorium. R. F. MACDOWELL. *Eng. News* 73, 1014-6(1915).—This was designed for a tuberculosis sanatorium for 250 persons. A 2-story settling tank, a dosing tank, a sludge bed, 2 intermittent sand filters (3 ft. deep), an absorption tile (1650 lineal ft. of 10 in. pipe) and a disinfection app. complete the equipment. The plant, including 2000 ft. of sewers, cost \$9,000.

L. PEARSE.

Success of two municipal garbage reduction plants. ANON. *Eng. News* 73, 1042.—The revenue at Columbus, O., pays the entire operating and fixed charges, including interest and depreciation. The cost of operation at Cleveland, O., was \$2.54, at Columbus \$1.86 per ton of garbage, with gross earnings, \$3.49 and \$3.08, resp.

L. PEARSE.

The typical Iowa sewage treatment plant and its proper operation. ANON. Report of San. Committee of Iowa Eng. Soc.; *Eng. Contrg.* 44, 7(1915). A. LEDERER.

The disposal of creamery refuse. H. R. CROHURST AND A. D. WESTON. *Eng. Contrg.* 44, 7-9(1915).—A summary of previously published data and conclusions bearing on the subject of creamery refuse disposal.

ARTHUR LEDERER.

Sewage disposal (tannery waste). J. M. SELTZER. *J. Am. Leather Chem. Assoc.* 10, 370-2(1915).—The effluent (95,000 gal. daily) from a tannery working 260 hides per day, is treated in a settling tank. There is a by-product formed for which no successful means of disposal have been found.

L. B.

The Great Lakes in their relation to typhoid fever. TALLAFERRO CLARK. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 122-30.—There is an undue prevalence of typhoid fever in cities and towns bordering on the lakes. Virtually all water supplies taken from the lakes are unsatisfactory for drinking without treatment. Wind is a factor of importance in distribution of harbor pollution. All of the lakes, with the exception of Lake Michigan, which is badly polluted in its southern portion, have water of a high degree of purity outside of the zone of pollution surrounding large cities or river outlets. The pollution in every case is due to sewage discharge from municipalities. Proper treatment of sewage before ultimate disposal is just as important as treatment of the water supplies used by the various municipalities.

D. K. FRENCH.

The sanitation of schools. TALLAFERRO CLARK. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 100-104.—A general discussion. School sanitation in addition to the medical inspection of the child considers the character of the water supply,

sewage disposal, ventilation and illumination. Considerable attention is paid to the influence of CO₂ and that of dust in connection with the health of the pupils.

D. K. FRENCH.

Disinfectants for clinical, surgical and sanitary purposes. HERBERT C. HAMILTON. *Am. J. Pharm.* 87, 315-23(1915).—Comparisons are made which indicate that even the ordinary coal-tar disinfectants when properly prepared are superior to phenol under all conditions, and surpass all other disinfectants aside from the purpose for which the latter are peculiarly adapted.

W. G. GAESSLER.

New York State Commission on ventilation. C. E. A. WINSLOW. *J. Am. Pub. Health* 5, 85-118(1915); *Science* 41, 625-32(1915).—The following tentative conclusions are indicated by the expts. of the first year. A room temp. 86° F. with 80% relative humidity, produces a slight elevation of body temp., an increase in reclining heart rate, an increase in the excess of standing over reclining heart rate, a very slight lowering of systolic blood pressure, and a marked fall in the Crampton value. There is shown no effect upon the rate of respiration, dead space in the lungs, acidosis of the blood, dissociation of oxyhemoglobin, respiratory quotient, rate of heat production, rate of digestion, carbohydrate or protein metabolism, conc. of the urine and skin sensitivity. Only the inclination and not the power to do work is diminished by a high room temp. A temp. of 75° and with 50% relative humidity has all of the effects noted for the higher temp. but in a less degree. Stagnant air, containing 20 pts. per 10,000 of CO₂ and other impurities of breathed air, if kept at fresh air temp., showed no effect upon (1) the physiol. responses above mentioned, (2) the power or inclination to do work, (3) the sensations of comfort of the subjects breathing it. It may, however, slightly reduce the appetite for food.

W. F. LANGELEIR.

Ozone—an aid to factory ventilation. V. D. GREENE. *Eng. Mag.* 49, 517(1915).
C. G. F.

Public health in Springfield, Illinois. FRANZ SCHNEIDER, JR. *Russell Sage Foundation*, May, 1915.—This is a report of 159 pp. covering a thorough sanitary survey. Particular comment is made on the water supply, sewerage, sewage disposal, milk and food supplies. The abolition of privies and private wells is urged. Both typhoid and venereal disease death rates are high.

L. PEARSE.

Stream pollution and sewage disposal. R. L. SACKETT. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 45-46.—S. emphasizes the necessity of protection against stream pollution rather than methods for purification.

D. K. FRENCH.

Stream sanitation. EARLE B. PHELPS. *Proc. 8th Ann. Conv. Ind. San. & W. S. Assoc.* 1915, 47-50.—A general article.

D. K. FRENCH.
